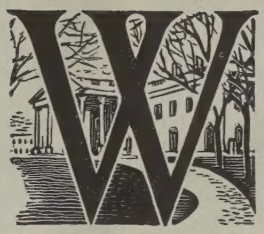
WASPS–ZYMOTIC DISEASE



WASPS, insects of the order Hymenoptera, most typically characterized by a narrow waist connecting the thorax and the abdomen. Ants, bees, sawflies, horntails, and a few others are also Hymenoptera. The remaining families of the order are known loosely as wasps, although the average observer would not think of them as wasps. They are often called flies, but this is a misnomer, as true flies of the order Diptera have only one pair of wings, while Hymenoptera have two pairs. These atypical wasps are mostly parasites and are extremely important in maintaining the balance of nature by destroying the plant-feeding insects which compete with man for food.

Parasitic Wasps.—The parasitic wasps include the ichneumons, braconids, proctotrupids, and chalcidoids and range from large species whose larvae feed internally on the bodies of caterpillars and other insects to minute forms whose entire growth can occur within an egg of a small insect. These minute wasps are among the smallest insects, some of them being only 0.21 millimeters (less than one hundredth of an inch) in length.

The majority of the parasitic wasps insert their eggs into the bodies of their living and active hosts by means of sharp ovipositors. The host insect continues its normal life until killed by the growing wasp larva or grub within. Most such wasps do not use their ovipositors as stings to defend themselves. A few, however, temporarily inactivate their hosts by means of a poison injected through the ovipositor. Such wasps may also sting in defense if picked up in the fingers. In more typical wasps the ovipositor has lost its original egg-laying function and serves only as a sting. The eggs are too large to pass through the sting and are laid from an aperture at its base. As the sting is a modified ovipositor, it is absent in all male Hymenoptera.

Typical Wasps.—It is an easily understood step from stinging parasitic wasps to certain more typical wasps such as Scoliidae which search for their prey, usually white grubs—larvae of June beetles (Scarabaeidae)—in the soil. Such a grub is paralyzed with a sting and an egg laid on it, after which the wasp goes on. Several of the natural enemies of the Japanese beetle, introduced from Japan in an attempt to control that pest, have such habits.

Nonsocial Wasps.—The next important step in wasp evolution appears to have been the establishment of a home, a nest, to which the wasp returns with its prey. (See NESTS AND NEST BUILDING.) The wasps discussed above have no such home, but simply wander about in search of hosts or prey. Most typical wasps, however, construct a nest, then paralyze the prey with a sting and carry it to the nest. The wasp places the prey in a small enclosed space (cell), lays an egg, seals the cell, and goes on to construct and provision other cells. This manner of providing food for the young is called mass provisioning. Such mother wasps never see their own young, for the cells are sealed immediately after egg laying and the mother is dead before her progeny mature and emerge. The advantage of paralyzing rather than killing the prey stored in the nest seems to be that the growing wasp grubs have fresh, in fact living, food to eat.

Among the many wasps whose behavior is as described above are the tarantula hawk (*Pepsis*), blue-black with red wings, and large enough to overpower and paralyze tarantulas; the cicada killer (*Sphecius*), a giant yellow-banded wasp that captures and paralyzes cicadas or locusts; the thread-waisted sand wasps (*Ammophila*), which put paralyzed caterpillars in holes in the soil as food for their larvae; the familiar mud daubers (*Sceliphron*) which make their mud nests on walls; and tiny black wasps (*Stigmus*) which fill their cells in pithy stems with paralyzed aphids or plant lice.

Wasps such as the above are called solitary or nonsocial because each female makes her own nest and never lives with her progeny. Some wasps, however, have become subsocial, that is, the food is provided progressively as needed by the larva. Some eumenid wasps provide whole caterpillars progressively, others partly chewed caterpillars, and a few chew up caterpillars into masses of tissue.

Social Wasps.—The latter method of feeding is that used by the social wasps (family Vespidae). These wasps are termed social because the mother is sufficiently long-lived to live with her mature progeny. The resulting colony is held together partly by exchange of food; the adults feed the larvae but also crave a secretion of the larvae. This mutual exchange of food is called trophallaxis. In such a colony the mother is the queen, while her female progeny are mostly slightly smaller, do not lay eggs, and are called workers. Nests of social wasps are nearly all made of wasp paper. Such paper, made from wood and stem fibers, was made by wasps millions of years before man learned the art.

The common social wasps of temperate climates pass the winter as fertilized young queens hidden in protected places. In the spring they come forth and usually each builds a small nest to rear her first progeny, all of which are females and mature as workers. After they are mature the queen ceases foraging and spends her time in the nest, where she lays eggs while the workers do

the foraging, enlarge the nest, and defend it. In late summer the queen's eggs, for reasons that are little understood, develop not into workers but into males and young queens. With cold weather all die except the young fertilized queens.

In North America there are two principal types of social wasps, each represented by numerous species. One type, the common paper wasps (*Polistes*), have small and usually timid colonies on exposed combs of paper cells hanging from eaves of buildings, branches of bushes or trees, and many similar localities. In fall the young fertilized queens often work into houses while searching for hibernating quarters. The other type constructs combs surrounded by paper envelopes. The colonies are much larger than in *Polistes,* and consist of hundreds or thousands of individuals having exceedingly painful stings. Those that nest in cavities in the soil (*Vespula*) are called yellow jackets while those that place their nests on branches of bushes or trees (*Dolichovespula*) may be called yellow jackets, although the larger species are often termed hornets. A single species introduced from Europe (*Vespa crabro*) nests in hollow trees and similar places and is called the European hornet.

Consult Wheeler, William M., *Social Life Among the Insects* (New York 1923); Michener, Charles D., and Michener, Mary H., *American Social Insects* (New York 1951); Richards, Owain W., *The Social Insects* (New York 1953).

and MARY H. MICHENER.

WASSAIL, wŏs"l (Anglo-Saxon *wes hāl,* be whole or have health), a greeting or toast on a special occasion, at the same time offering a beverage and drinking a health. In medieval times and earlier, a bowl was prepared with ale or wine, flavored with sugar, spices, toast, and fruit, like the modern punch, probably heated by plunging a redhot poker in the mixture. Groups of people went from house to house on Christmas and Twelfth Night, singing carols, and were offered the wassail bowl at each stop. This is the origin of the old English carol *Here we come a-wassailing* . . . In Shakespeare's *Hamlet,* Act I, scene 4, Hamlet says:

> The king doth wake tonight and takes his rouse,
> Keeps wassail . . .

An old poem of Robert de Brunne (13th century) describes the custom of offering the wassail bowl to a guest, with the proper response, "Drink hail." A wassail is sometimes used to denote a drinking song, and wassailers came to mean drunkards, as in John Milton's *Comus.*

WASSERMANN, väs'ĕr-män, **August von,** German bacteriologist: b. Bamberg, Bavaria, Feb. 21, 1866; d. Berlin, Germany, March 15, 1925. After studying at the universities of Munich, Erlangen, Strasbourg, and Vienna, Wassermann began practice as a physician in Strasbourg in 1888. Under Robert Koch (q.v.) he was director of the department of experimental therapy and biochemistry at the Koch Institute for Infectious Diseases, Berlin, and later was director at the Kaiser Wilhelm Institute in Berlin-Dahlem (1913). He developed antitoxin treatment of diphtheria, inoculation against typhoid, cholera, and tetanus, and did valuable work in pre-tuberculosis cases. He also worked out a differentiation classification for blood groups. His work in diagnosing syphilis is best known. Working with Albert Neisser and Carl Bruck on the Bordet-Gengou reaction, he discovered a complement-fixation test for syphilis, which is called by his name (1906).

Wassermann Reaction or Test.—A serum composed of an extract of the *Spirochaeta pallida* is used to test the presence in the blood or spinal fluid of antibodies which have been formed as the result of an infection of syphilis which affected tissue cells. This may be found even though evidence of the disease is not observable at the time. If the patient is syphilitic the complement in the serum will not dissolve the red blood cells; if syphilis is absent, the cells are dissolved, producing a clear fluid in the test tube. Sometimes a positive reaction is obtained from yaws, leprosy, malaria, and infectious mononucleosis. Also, a positive reaction may be had from the spinal fluid, and a negative from the blood. Nevertheless, the Wassermann test, even though simplified by later research, is still considered the most reliable, and in some states, the test is required for a premarital medical certificate.

WASSERMANN, Jakob, German-Jewish novelist: b. Fürth, Bavaria, March 10, 1873; d. Alt-Aussee, Austria, Jan. 1, 1934. Wassermann's early years were spent in extreme hardship, but after his stories and poems appeared in *Simplicissimus,* he went on to attain fame and recognition as one of the foremost German writers. In 1896 his novel *Die Juden von Zirndorf* (tr. as both *The Jews of Zirndorf* and *The Dark Pilgrimage,* 1933), introduced a writer of great narrative ability who employed strange characters and posed interesting problems. In 1898 he went to live in Austria. Among his novels were *Caspar Hauser* (1908; Eng. tr., 1928); *Das Gänsemännchen* (1915; Eng. tr., *The Goose Man,* 1922); *Christian Wahnschaffe* (1919; Eng. tr., *The World's Illusion,* 1920); *Der Fall Maurizius* (1928; Eng. tr., *The Maurizius Case,* 1929); *Etzel Andergast* (1931; Eng. tr., 1928); its sequel, *Joseph Kerkhoven's dritte Existenz* (1934; Eng. tr., *Kerkhoven's Third Existence,* 1934). His autobiography, *Mein Weg als Deutscher und Jude* (1921; Eng. tr., *My Life as German and Jew,* 1933), expressed the difficulties of the Jew in Europe even before the Nazi anti-Semitism.

Consult Blankenagel, John Carl, *Writings of Jakob Wassermann* (Boston 1942).

WASTE, *in law,* the result of any act or omission by the tenant of any particular estate by which it is rendered of less permanent value. Waste is of two sorts, *voluntary* and *permissive.* The former is that caused by active procedure on the part of the tenant, such as the destruction or alteration of buildings, the removal of fixtures, the cutting down of fruit or shade trees or ornamental shrubs, or in the case of a wood lot, the removal of timber trees and cordwood and their sale for the benefit of the tenant. The latter may, however, cut such timber as is needed and used in the repair of the buildings on the estate. Permissive waste is that caused by negligence, such as the allowing of buildings to fall out of repair. Under the law of waste a tenant may work any mine or quarry already in existence on the leased property unless specifically forbidden in the lease. But he is not permitted to open and operate for his own gain either mine or quarry. In some states of the United States the tenant is permitted to clear up wild land for agricultural

purposes; but he must not sell the product of such clearing in cordwood or lumber for his own emolument. On the theory of permissive waste as developed at common law is based the rule which throws upon the tenant the responsibility of making all ordinary repairs in the premises which he occupies. Though he cannot strictly be required to make repairs, and is not liable in damages for any failure so to do, yet in case of an action for waste against him his only defense is a demonstration that he has repaired the waste, and he, therefore, prefers to maintain the premises in repair.

WASTE, or BY-PRODUCTS. Waste is that portion of raw material used in any specific manufacture which is in the process rendered useless for that particular line. However, the name is sometimes retained long after a substance, at one time of little or no value, has been utilized as raw material in some other industry. In every manufacturing process, mechanical or chemical, there is more or less left over material which becomes waste. The examples given below relate to new waste, but nearly everything we use wears or corrodes, or gets broken or unshapely, and so rags and rust and scraps arise. On the other hand, the rust which arises from corroding iron is utter waste, since it can never be profitably collected at all. There is a kind of waste, for the most part difficult to prevent, which goes on in the consumption of fuel, and in certain processes of roasting or calcination in the smelting of metals. Roundly speaking, the best designed steam-engines and boilers require only half as much coal per horse power per hour as those less skilfully constructed, and the fuel unnecessarily consumed by bad boiler furnaces is largely wasted as smoke through imperfect combustion. The utilization of blast furnaces gases for heating purposes, and the recovery of tar and ammonia also produced at the same time from the coal consumed in these furnaces, form an instance of a double saving from the same source. In the report of the chief inspector of alkali works for 1891, it is stated that the plant put up in recent years for collecting tar, ammonia, etc., at 57 Scotch blast furnaces cost $2,223,000, a sum fully equal to the cost of building the furnaces themselves. The condensing flues, miles in length, connected with some lead-smelting furnaces are modern examples for appliances to condense lead fumes or vapor which formerly was allowed to escape, causing much loss of the metal.

Some instances of how waste in a solid form arises in working rock and other mineral substances may now be given. In shaping and dressing granite paving stones as much as three-fourths of the rock quarried is, in some instances at least, wasted. This waste is as yet only in very small part utilized for road metal, and for "granolithic" pavements. Blast-furnace slag is now utilized in several ways, notably in the manufacture of Portland cement. In a number of cases the accumulations of other kinds of slag on the sites of ancient smelting works have, in modern times, been again put through the furnace to extract the metals left in them, with profitable results. Some of the refuse from the old silver mines of Laurium has been bought up by capitalists for this purpose. One instance though not of very recent date, may be given where, by the salvaging of a by-product, a fortune was very quickly amassed. About 1840 Mr. Askin of Birmingham discovered a method of separating cobalt, in the form of oxide, from nickel, two metals which were very difficult to separate. This oxide of cobalt was at first a waste product, but before very long it was put into the hands of potters, who readily bought it up to produce a blue color on their ware, at the rate of two guineas per pound. Among comparatively recent instances of utilization of by-products and waste products in the chemical industries, we may refer to the importance of the substances now developed from coal tar (q.v.), and the great value of some of them in the manufacture of dyes. Another example is the recovery of binoxide of manganese in the production of chlorine for the manufacture of bleaching powder by Weldon's beautiful process. Formerly for every 100 pounds of bleaching powder made about 100 pounds of the native oxide of manganese were required. Now this manganese is recovered and used again and again in the process, with only a loss of about 5 per cent to make up each time it is returned to the chlorine still. The earlier methods of recovering manganese were not nearly so perfect, and, therefore, were not much used. A process for the utilization of chemical waste on a great scale is Chance's method, patented in 1888, of recovering sulphur from alkali makers' black-ash refuse. A British automobile manufacturing concern salvages 1,200 gallons of cutting oil a week from scrap metal, this oil being used again with the addition of 10 per cent of new oil, the latter being the actual amount of unrecoverable waste. Another establishment treated in one year 83,400 pounds of lathe waste, recovering 2,292 gallons of cutting oil. Large quantities of machine oil are recoverable from rags and cotton waste used for wiping machinery. The process of oil recovery so cleanses the wipers that they are useful again. The year's report shows 350,000 wipers treated, and an annual replacement of only 15,000 new cloths required; and a recovery of more than 5,000 gallons of oil — the total cost of the operation being less than $1,000.

Passing to vegetable substances, the various materials besides rags used in the manufacture of paper may be first noticed. Straw, wood, and esparto fibre, if not exactly waste products, were at least undeveloped substances before they became, as they now are, so largely used in paper making. Old ropes, flax and jute-mill waste, old or torn pieces of paper of every kind, are all serviceable in paper-mills or in the manufacture of millboard. In the pulp of the latter old newspapers bulk largely. Cotton waste is much used by mechanical engineers for cleaning purposes. Sawdust is employed in several ways: in the manufacture of artificial wood, which is pressed into many architectural forms; as a source of oxalic acid, and of pyroligneous acid; and, when compounded with magnesium chloride, as a durable, warm and resilient coating for the cement floors of fireproof buildings. Chips of yellow pine from Southern shipyards yield turpentine and rosin to the waste industry. One of the most interesting developments of all is the manufacture of artificial silk from the wood waste of saw-mills and carpenter shops. The timber

wastes of the United States are prodigious; the estimate for 1913 placing the total at 150,000,000 tons. One of the most effective activities of the Forest Service is directing the salvaging of this waste and its delivery into the hands of establishments which will utilize it. The waste liquors of the wood-pulp industry yield alcohol, adhesives, tanning agents and thymol; and a recently discovered Norwegian process for separating the lignin makes that substance available for fuel — in amount nearly or quite enough to furnish all the heat required in making the pulp. Molasses, a waste product of sugar making, besides being a food, yields large quantities of industrial alcohol at low cost; and, as a by-product to this manufacture, yields valuable potash salts. Corkcutter's waste has become of high importance in the manufacture of linoleum and cork carpet. Cork mattresses and life-preservers, compressed with shellac into new bottle corks, for lining refrigerators and as a substitute for shavings in vinegar making. From the bark stripped from osier wands the useful medicine salicin is now made. In days not so long past the spent madder of our large dyeworks was suddenly raised from a useless to a valuable material by treatment with sulphuric acid, which converted it into the dye called garancin. One of the most interesting examples of what has been done in converting a waste animal product into a highly useful material is seen in the case of waste silk. Cocoons do not yield half their weight of reeled silk, but the remaining «waste» portion has, through the ingenuity of an English inventor, become the raw material for a large spun silk industry. In Venice artificial flowers for ladies' headdresses are made of imperfect cocoons. The various kinds of waste from woolen mills and from the cutting up of woolen fabrics are either worked up again, the short fibre into mungo and the long fibre into shoddy, or it is used for felt or ground into flock for paper hangings. Glue (q.v.) is made from parings of hide and bone, which also yield glycerine. The turnings and dust of the ivory and bone turner have various useful applications. From almost any waste animal matter, such as parings of horns and hoofs, hair, blood, leather cuttings and even field mice, is made the whole list of the invaluable cyanides. The waste of leather cutting is compounded with waste or scrap rubber in the production of a waterproof artificial sole leather. Clippings of fur skins are made into hats and fish scales into artificial pearls. The waste of mother-of-pearl left by button cutters is converted into a fine powder of peculiarly beautiful silky lustre, and used in making artificial flowers and fine wallpapers. The skim-milk residue of butter factories is made into a grade of condensed milk or treated as a source of commercial casein, the whey being worked for its content of milk sugar. The waste bone-charcoal of the sugar refineries is treated with sulphuric acid to make the valued bone phosphate fertilizer. Other materials regularly dealt in by the dealers in waste include old twine, old oilcloth and carpets, books and magazines, old hats, broken glass and old bottles, moss, hair, fur, bones and many others.

The enormously increased prices following the entrance of the United States into the World War gave a market stimulus to the waste industry, owing to the increased values which waste assumed. The larger establishments found it profitable to organize individual salvage departments, in some cases costing into the millions; equipped with complete outfits for treating all sorts of waste. It has been stated that the national savings during the war in scrap metal, wool waste, paper, rags, bags and cotton linters were more than $1,500,000,000.

By destructive distillation of coal Ford converts a ton of bituminous into 8,000 cu. ft. of gas, 10 gals. of gasoline, 20 lbs. ammonium sulphate, 30 gals. crude light tar, 3 gals. creosote oil, 2 gals. crude lubricating oil, 10 lbs. grease and has left 1,500 lbs. coke. The net money loss of present practises is estimated at $2,000,000,000 which could be salvaged by the proper use of coal including doubling the horse-power and salvaging the ammonium sulphate, benzol, tar, creosote oil, etc.

Smaller establishments disposed of their waste at good prices to one of a large and competitive throng of dealers. The waste trade has its own directory which lists more than 30,000 concerns who either deal in wastes or who use these wastes as raw material in their own industries. Some 6,000 of these dealers are in foreign countries, and not only sell their own domestic waste, but buy at good prices the wastes of American industries. Consult Koller, T., 'The Utilization of Waste Products' (London 1918); Kershaw, J. B. C., 'Recovery and Use of Waste' in 'Industrial Chemist' (1926).

WASTE LANDS, uncultivated and unprofitable tracts in populous and cultivated countries. The term waste lands is not employed with reference to land not reduced to cultivation in countries only partially settled. There is a large extent of waste lands even in Great Britain. Of the total 56,107,000 acres which it contains (excluding water), only 30,280,000 acres are arable land and improved pastures; 2,736,000 acres are occupied by woods and plantations. In Scotland 9,710,000 acres were rough grazing land in 1926, generally at considerable elevation and little improved by art. In a recent year in Ireland 8,000,000 acres were uninclosed pasture, 3,000,000 acres were mountain and bog; and the remainder was unimproved and unproductive.

In the United States, much of the land now practically waste is in this condition merely because the time has not yet come for profitable development of its capacities. That brought under cultivation is remarkably productive. The report of the Department of the Interior declares that on 1 July, 1931, the acreage of «unappropriated and unreserved lands» in the United States was as follows:

	Surveyed lands	Unsurveyed lands	Total
Arizona	7,489,400	6,877,000	14,366,400

WASTES, Disposal of City.—The public wastes of a city may be grouped into two very broad classes: sewage, including industrial chemical wastes; and refuse. The first class is specifically treated under the title SANITARY ENGINEERING and elsewhere in these volumes.

Refuse.—This second broad class of city wastes includes garbage, ashes, street sweepings, rubbish, dead animals, night soil, swill, slops, offal, trade wastes, and other putrescible and nonputrescible wastes, except the liquid-carried wastes normally discharged into sewers. With the increased use of garbage grinders quantities of garbage are being discharged into the sewerage system and handled in the same manner as the wastes discussed under SANITARY ENGINEERING—*Sewage Treatment.*

The primary consideration of the problem of refuse collection and disposal is proper sanitation. The public health significance of the problem differs with the nature of the waste material. Sanitary methods of handling and disposal of garbage, street sweepings which may contain manure, and certain other refuse that contain organic waste constituents are important because these wastes may attract and serve as food supplies for flies, cockroaches, and rodents. Rubbish, paper, and other dry wastes may serve as harborage for rats and insects. Nuisances resulting from improper handling of garbage and refuse include disagreeable odors, breeding of insects and rodents, and unsightly, filthy esthetic conditions.

The second most important consideration is the attainment of satisfactory results with a minimum expenditure of funds. Refuse collection, storage, and disposal are fundamentally engineering problems requiring the application of the principles of engineering design and management. The problems vary in each community but their complexity is common to all. A thorough study of local conditions and technical problems that are encountered in the initiation and operation of a satisfactory refuse disposal program at lowest possble cost should come under the jurisdiction of a sanitary engineer or sanitarian qualified to undertake this type of study.

Refuse is a general term that includes many different substances from a great number of sources, including all solid or semisolid waste materials with the exception of excreta. It may be classified as to source, examples being market refuse, stable refuse, house refuse, and street refuse; but it is generally divided into several classifications as to type: (1) garbage; (2) ashes; (3) rubbish; (4) dead animals; (5) night soil; (6) street sweepings; and (7) mixed refuse. Each of these classes of refuse will be described briefly and the different methods of collection and disposal will be discussed subsequently.

(1) Garbage comprises all putrescible wastes of vegetable or animal matter originally intended for or associated with food for human consumption. It includes all waste materials from kitchens of homes, restaurants, hotels, and institutions, together with the putrescible organic waste materials from markets, groceries, and abattoirs. It requires careful collection, storage, and handling, especially during warm weather, when it decomposes quickly and gives off offensive odors. As mentioned previously, it also attracts flies, insects and rodents. However, garbage is also the most valuable of any of the classes of refuse, as it may be used in feeding hogs and it may yield grease and fertilizer by reduction processes which are described under methods of refuse disposal. Research is being carried on in the United States at the present time to improve the methods of composting garbage to convert the easily putrescible organic matter into a stabilized humus usable as fertilizer.

(2) Ashes are the waste products of coal and other fuels used for cooking, in the heating of homes and for industrial purposes. The amount of ashes produced fluctuates with the seasons, being highest in the winter. The amount also is dependent upon the geographical location and climatic conditions. Ashes may differ considerably in quality depending upon their source and the type of fuel used. They may also contain considerable amounts of unburned combustible material, some incombustible material, such as tin cans and other metallic substances, broken glassware, and crockery. The amounts of ashes being produced have decreased considerably in the past few years because of the increased amounts of gas and oil being used as fuels.

(3) Rubbish is any dry nonputrescible household or business wastes that are not classified as garbage or ashes. It includes paper, rubber, rags, cartons, excelsior and other packing, discarded furniture and other wood, glass, crockery, leather, sweepings, metal, and other articles. It is synonymous with the term "trash." Rubbish is normally not putrescible, but may contain floor sweepings contaminated with pathogenic bacteria or cans containing small amounts of putrescible materials.

(4) Dead animals may be collected by the municipal refuse collection service from stables, riding academies, dairies, zoos, race tracks, and even visiting circuses and rodeo troupes. In some cities private companies may perform this service, although they usually do not collect small animals, the latter being collected by the cities. Dead animals are usually disposed of by burial, incineration, or reduction. They should be buried deep enough to prevent dogs or other carnivorous animals from digging them up. Larger animals, such as horses, cattle and mules, are generally skinned and their hides sold.

(5) Night soil is a term applied to the solid and liquid human excrement collected from box-and-can toilets, private privy vaults, and other receptacles for excreta disposal in those areas without water-carriage sewer systems. The term "night soil" originated from the fact that before the advent of sewer systems large numbers of privy vaults were then in use and when they became full were emptied at night. This method of human waste disposal has been outlawed in the cities of the United States although many are still in use throughout the country in outlying sections of the larger cities as well as in the smaller towns and rural areas. It is primarily a rural problem.

In many parts of the world, notably Formosa, Japan, China, and India, the night soil is of con-

siderable economic value as fertilizer. In South Africa over 100 cities and towns mix night soil with garbage and other putrescible organic waste materials in compost pits to produce fertilizer for their agriculture.

(6) Street sweepings consist of the dust from the wear and tear of the road surfaces, paper, leaves, branches of weeds and trees, cigarette and cigar butts, sweepings from stores and sidewalks, materials that have fallen from vehicles, and many other types of litter. Education of the general public, backed up by effective police control, can help to reduce, if not eliminate, unnecessary littering of the streets which adds to the expense of street cleaning. New York City has recently instituted a program to promote a cleaner city by empowering all supervisory personnel of the Department of Sanitation with police power to hand out summons to appear in court for any violation of the Sanitary Code, including the promiscuous littering of streets with paper and other refuse. (See STREET CLEANING.)

(7) Mixed refuse consists of one or more combinations of the various refuse materials of a community to facilitate their collection and disposal. Rubbish and garbage are often collected together, when the mixture will be disposed of by incineration. Other common combinations are rubbish and ashes, combustible, and noncombustible mixtures, one mixture being placed in one container and the remainder in another, dependent upon the final method of disposal. With the sanitary land-fill method it is unnecessary to separate the refuse into its component parts.

Quantities and Characteristics of Refuse.—The quantities of refuse in any community are dependent on many factors, including climate, season, habits of the people, geographical location of the community, nature or type of community, economic period, and efficiency of collection service.

Garbage weighs between 30 to 55 pounds per cubic foot, dependent on moisture content, which varies from 50 to 70 per cent. Ashes weigh from 40 to 50 pounds per cubic foot, while rubbish is much lighter in weight, varying from 20 to 25 pounds per cubic foot. In cities requiring that garbage be drained and wrapped the weight is lowered proportionately to the amount of moisture removed.

The total weight of refuse in a city varies considerably but averages about 2 pounds per capita per day. Of the total weight, garbage constitutes about one fourth of the weight and one fifth of the volume, or varies from a minimum of about 0.3 pounds to a maximum of 2.3 pounds per capita per day in different cities. Rubbish constitutes about one third of the weight and one half of the volume of the total amount of refuse of a city. This variation in weight and volume must be carefully considered in providing an efficient, economical, and sanitary refuse collection service.

The composition of refuse varies widely, making it almost impossible to predict the amounts of its different components. Therefore, it is very essential to obtain accurate weights and volumes and to maintain accurate records to determine costs of refuse collection and disposal. Chemical analyses may aid in determining the value of by-products obtainable, such as grease, feed for hogs and cattle, or fertilizer.

Municipal Refuse Disposal.—The problem of municipal refuse disposal is divided into three separate phases: house treatment; collection; and disposal.

House Treatment.—This consists of the handling or treatment of refuse by the producer in the home or business place before collection. The treatment that it receives plays an important role in sanitation. Odors may be almost eliminated or reduced for several days if garbage is drained and wrapped, or mixed with ashes and rubbish in the receptacle for collection. The most important nuisance from rubbish is due to loose paper. Mixing of garbage with the rubbish moistens the paper and helps to eliminate this problem.

The most common method of house treatment in the United States is the separation of the refuse into two cans. The garbage is usually placed in one can, and the rubbish and ashes are placed in another. This is a very satisfactory method where either hog feeding or reduction is the method of disposal.

The receptacle used for the storage of refuse before collection should be of material suitable to receive the wastes and be provided with a tight-fitting cover. In most cities metal receptacles are recommended for storage of garbage and ashes. The size of the container required is partly dependent upon the amount of garbage and refuse to be stored between collections, but it must not be so large that it is difficult to empty into the collection vehicle. The maximum size recommended for separate garbage storage and collection is 10 or 12 gallons, and for combined garbage and domestic refuse a 30-gallon container with a weight limit of 65 pounds when full is preferable for easier handling.

In New York City very large enclosed metal containers are placed in certain locations where large volumes of refuse are produced, such as at hospitals, schools, markets, and apartments. When full, they are lifted onto a large truck by means of a hoist, an empty container is substituted, and the full container is hauled away.

Collection of Refuse.—The method used in most communities in the United States for the collection of refuse consists of a gang of two or three men with a vehicle. The men pick up the refuse containers from each house and place the cans or their contents into the vehicle and transport it to the place of disposal. The vehicle may be an open-body type or the more sanitary, enclosed, compaction-type truck, of which there are several designs. The vehicles with compacting units have a hauling capacity of 35 to 50 per cent more than the open-body trucks. Based on an average wage of $1.50 per hour, it was shown in a 1952 survey of several California towns that the average labor cost of the pickup operation was $3.71 per ton and the total collection operation amounted to $5.37 per ton.

Problems considered in the efficient operation of any refuse collection system are: frequency of collection; time of collection; type and size of vehicles; number and efficiency of men in collection crews; length of haul to place of disposal; method of administration, whether by municipal personnel, by private contractors, or by a combination of the two.

Factors considered in the selection of refuse collection trucks are: ease of loading; low-loading height; speed of loading; compactability; reliability; maintenance costs; and original cost of vehicle.

Disposal of Refuse.—The method selected for the disposal of refuse should perform its function with the least production of nuisances and in the most economical manner. The refuse disposal methods include the following: dumping upon the land; dumping into the sea; incineration; sanitary landfill; hog feeding; garbage grinding; reduction; and composting.

Sufficient space is not available to discuss all of these methods in detail, and since dumping on land, dumping at sea, and incineration have already been covered adequately under the title SANITARY ENGINEERING, they will not be discussed in this article. An excellent discussion of sanitary landfill, hog feeding, and garbage grinding will also be found in the above-mentioned article but additional comments will be made here. The two other methods, reduction and composting, will be discussed in subsequent paragraphs, as they have not been included elsewhere in these volumes.

Sanitary Landfill: This method of refuse disposal is distinguished from the open dump by the fact that the garbage, ashes, street sweepings, and rubbish are dumped in layers of controlled depth and width in a trench or depression and the material compacted and covered at the end of each working day with a layer of clean dirt, sand, or ashes to a depth of 2 or 3 feet, to exclude rodents and prevent the escape of odors or the outbreak of fires. A single bulldozer or dragline with an operator can operate a landfill handling 3,000 to 4,000 cubic yards of refuse per year. An area of 0.75 to 1.5 acres per 10,000 population per year is sufficient where the refuse is placed in layers to an average depth of 6 feet.

Hog Feeding: The feeding of garbage to hogs is operated as a profit-making venture. With this being the primary objective, public health departments have considerable difficulty in attempting to persuade hog farmers to maintain some semblance of sanitation in their operations. The nature of the activity itself together with economic and political considerations makes it almost an impossibility.

In the United States most public health authorities frown on hog feeding as a method for the disposal of raw garbage because of the high incidence of trichinosis infestation among these hogs. The United States Quarantine Regulations now require that garbage fed to hogs to be sold in interstate commerce must be heated at 212° F. for 30 minutes. Most health authorities recommend the heating of garbage which may contain trichinae larvae to prevent hogs from becoming infected with these worms that may infect man upon the consumption of insufficiently cooked meats from garbage-fed hogs.

Many states have recently required the heating of garbage at a minimum temperature of 145°F. for not less than 30 minutes to prevent the transmission of vesicular exanthema, a disease of hogs almost wholly confined to farms feeding raw garbage.

In England and Wales in 1940 a program for the separate collection of garbage was instituted on a national scale in order to salvage this material for the feeding of hogs due to the serious shortage of imported animal foods. Over 60 sterilization stations were built for the purpose of heating the garbage to 212° F. for 1 hour to destroy the virus of foot-and-mouth disease which had caused many extremely costly and wasteful outbreaks of this disease on their hog farms.

Garbage Grinding: Every year, increasing numbers of garbage grinders are being installed in homes for the disposal of garbage into sewers. In the past few years several municipalities, following the example of Jasper, Indiana, have installed home grinders on a citywide basis. Jasper purchased the units in large quantities at a low price, resold them at cost to the home owner under a monthly-payment arrangement, and provided maintenance, all for a total cost of $0.66 per family per month, including interest. Many cities prohibit the installation of home grinding units because of the increased amount of organic sludge load placed on the municipal sewage sludge digestion facilities already operating at maximum capacity.

Reduction: This is a method of processing garbage and dead animals to recover grease and produce tankage used as livestock feed or as fertilizer. Two general procedures for garbage reduction are in use, the cooking method and the extraction method. In the cooking method the garbage is cooked in closed tanks to prevent the escape of odors. The grease and water are then pressed out of the cooked material and the grease is skimmed from the surface of the water. Additional grease is extracted from the filter cake by an organic solvent such as naphtha or gasoline. The filter cake is then dried, ground, and sold as tankage for the manufacture of fertilizer or cattle feed. In the extraction method, the garbage is first ground, dried, and then treated with an organic solvent as by the previous method. About 1 to 8 per cent of grease and from 10 to 20 per cent of tankage by weight may be recovered from garbage. During the past few years many plants have been abandoned as unprofitable either because of operating difficulties from escape of odors or because of explosive hazards.

Composting: This is a biological method of altering the composition of garbage and other organic material, resulting in a stable humus-like end product usable as fertilizer. The composting process consists of placing the raw materials in piles or in concrete or brick cells, then allowing the mass to ferment through the action of bacteria and other microorganisms. Heat is generated, and the resulting high temperature, 140° F. to 180° F., is sufficient to destroy pathogenic organisms. Mixing of the mass is essential, varying from one or two manual turnings to continuous mixing by mechanical means. The mixing provides aeration so that the fermentation will proceed under aerobic conditions in preference to the slower-acting anaerobic process.

This is an age-old process for the conservation of organic waste products, including night soil, which has been developed with considerable success in many countries, notably Denmark, France, Italy, and throughout the British Empire. In South Africa this method of composting has been developed by using garbage, night soil, bat and kangaroo manure, farm manure, and abattoir wastes as raw materials for the production of fertilizer. The chief operating difficulties with composting are fly breeding, odors, and proper drainage.

WATCH HILL, post village in Westerly Township, Washington County, R.I., on the Atlantic Ocean, and about three miles southeast of Stonington, Conn. It is near Watch Hill Point, a promontory forming the extreme southwest point of Rhode Island. The place has a fine beach and ranks next to Newport and Narragansett Pier, in Rhode Island, as a popular summer resort. Pop. (1950) c.500.

WATCHMAKING, Modern. The history of watchmaking covers nearly 500 years of dramatic technical progress and intense international rivalries. In that period four nations have struggled for supremacy in the industry, even resorting to the use of spies and smuggling, and today (1950) the competition is as keen as ever.

Structure of Watch Movements.—The jeweled watch of quality (15 to 23 jewels) is a complex mechanism consisting of 135 to 140 pieces and requiring from 2,500 to 3,000 manufacturing operations. Its structure is described by Walter Kleinlein of the Waltham Watch Company as follows. There are four principal assemblies in a watch movement: (1) the power plant consisting of the barrel, the mainspring, and its attachments; (2) the train of toothed wheels and pinions, through which the power of the mainspring is transmitted; (3) the escapement assembly, which stops and releases the transmission of power; (4) the balance and hairspring assembly, which governs the period of time in which each release of power is made. The hands and dial assembly complete the operations by indicating the timekeeping performance of a watch.

The escapement is one of the most important elements in the watch, and its operation is worthy of more detailed description.

Fig. 1 shows a diagram of the detached lever escapement, which consists of four parts: (1) the escape wheel; (2) the pallet and arbor assembly; (3) the adjustable banking pins; (4) the balance staff and roller assembly. The energy of the mainspring is transmitted through the train to the escape wheel. Pressure of the teeth of the escape wheel on the pallet jewels sets up an oscillating motion of the pallet and fork, which is transmitted to the balance wheel and hairspring. The accuracy of the watch is controlled by the precise design and adjustment of these parts to each other, and by the reduction of friction through the use of jeweled bearings. Quality jeweled watches require adjustment for four basic factors: (1) isochronism, (2) timing, (3) temperature, and (4) position.

Isochronism is the maintenance of a constant rate of operation as the watch runs down after winding. In a clock this is accomplished by the use of a pendulum of constant length and weight swinging under the constant influence of gravity. In a watch the rate is kept relatively independent of the changing force of the mainspring by the oscillation of a poised balance wheel of constant mass and fixed center of gravity, operating under the constant influence of the hairspring.

Isochronism involves two major problems of design: (1) The balance wheel must be poised, that is, its weight must be uniformly distributed so that the force of gravity will not affect its oscillation. (2) The design of the balance wheel and the hairspring must be such that their oscillating motion does not alter the force exerted by the hairspring or the resistance offered by the inertia of the balance wheel.

Poise is obtained by the adjustment of radial screws in the rim of the balance wheel. Metal is removed from the underside of the head, or heavier screws are added above, until the wheel, when mounted in poising calipers or poising tool, rotates freely and is not more disposed to stop in one position than in another.

Timing.—Timing is obtained by adjusting the

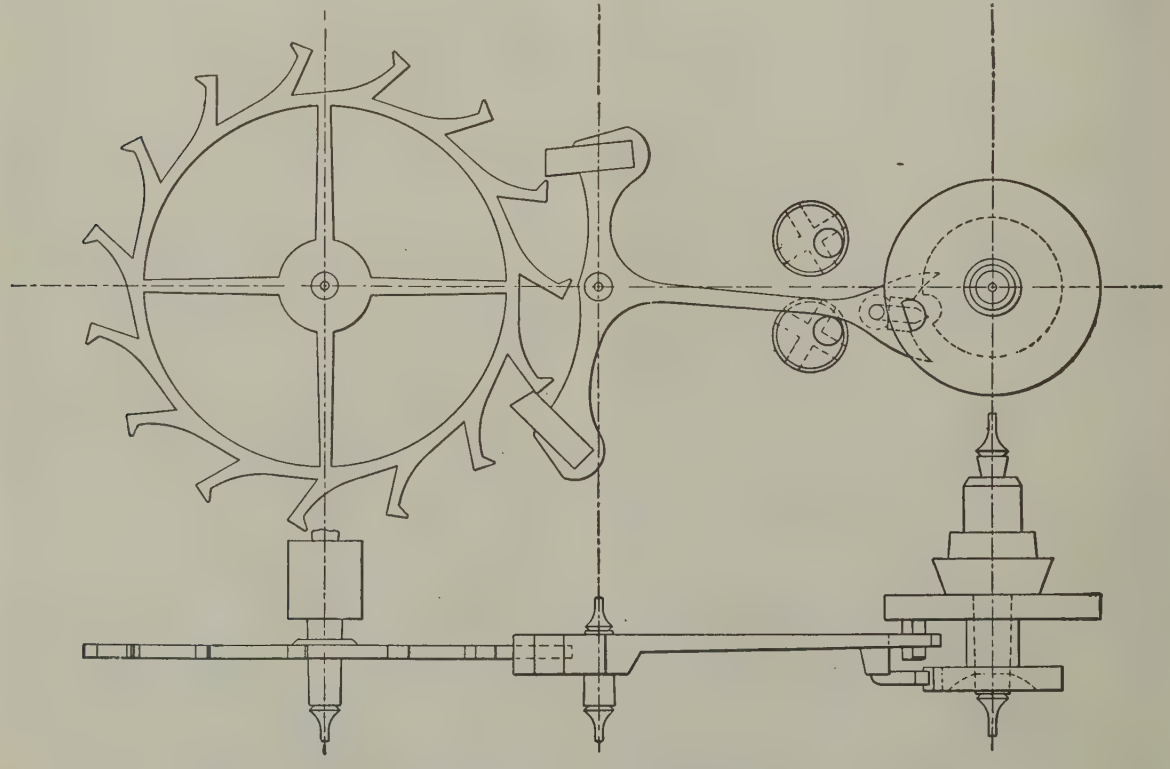

Fig. 1. Double roller escapement.

strength of the hairspring to the oscillating force of the balance wheel. This is called vibrating, and involves obtaining the correct number of oscillations per hour for which the watch was built. In modern watches this consists of 18,000 oscillations per hour. This means that through the operation of the escapement, the balance, and the hairspring, the train of wheels (and therefore the timing) of a modern watch is stopped and again released 18,000 times per hour, or 432,000 times in a 24-hour period.

Adjustment of steel hairsprings for changes in temperature is accomplished by making the rim of the compensation balance wheel of two

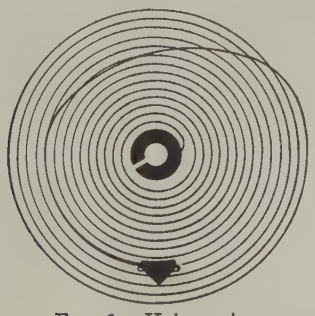

FIG. 2. Hair spring.

sections of bimetallic metal, fitted with adjustment screws (Fig. 3). The outer strip of brass is brazed to the inner strip of steel. An increase in temperature expands the whole wheel, tending to increase its inertia, but the greater expansion of brass compared to steel shortens the radius of curvature, as in Fig. 4, counteracting the effect of simple expansion. Adjustment is accomplished by shifting the screws to various positions on the rim.

Methods of Correcting Temperature Variation.—Fig. 4 shows an extreme distortion of both sections of a bimetallic compensation balance wheel in high temperature. The free ends curve

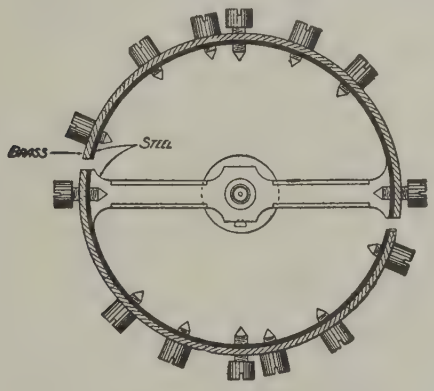

FIG. 3. Bimetallic balance wheel.

inward from true concentric as the temperature increases from normal; shifting screws to different holes toward the cuts and in opposite pairs causes additional weight to move nearer center. This alteration supplies a gaining rate to overcome the loss produced by the increased length and lessening of elasticity of the steel hairspring.

Inversely when the temperature decreases the free ends curve outside of true concentric. This causes a loss at the same time that the hairspring supplies a gaining rate due to its becoming shorter and stronger. In this case screws are moved away from the cuts when the variation is above tolerance and a correction is required.

By using a solid monometallic balance wheel and a hairspring, each containing alloys with a very low coefficient of expansion for temperature changes, there is no need for mechanical temperature adjustment. These alloys have the further advantages of being virtually nonmagnetic and rustproof.

A solid rim monometallic balance wheel is shown in Fig. 5.

Adjustments are made for as many as six positions: stem up, left, right, down; dial up and dial down. Approximate adjustment is obtained by poising the balance wheel, thereby

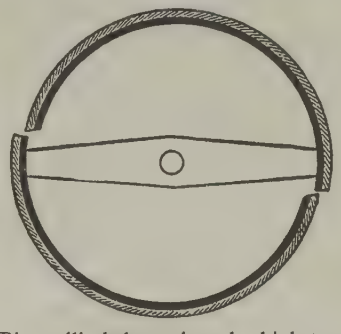

FIG. 4. Bimetallic balance bent by high temperature.

eliminating the effect of gravity upon the oscillation of the wheel. Other adjustments are made to correct the effect of gravity on the hairspring and the various jeweled bearings of the movement.

Production.—The production of watches began in central Germany about 1500, and from this section came the bulky timepieces known as Nürnberg eggs. Two hundred years later the leadership of the industry passed to the English, for German ingenuity was no match for specialized English craftsmanship. English leadership lasted some 140 years, but by 1840 the Swiss had

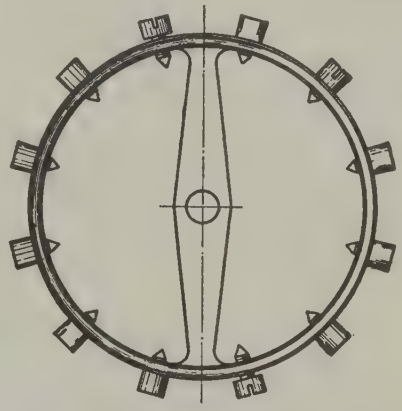

FIG. 5. Monometallic balance wheel.

acquired such superlative skill in the same manufacturing methods used by the English that they, in turn, seized the dominant position in the watch industry. The craftsmanship of Swiss watchmakers has probably never been surpassed, but in the 19th century manual skill was not sufficient to maintain a position of leadership in the industry, and first place was forfeited to the United States. Beginning in 1850, a new firm, later known as the Waltham Watch Company, applied to watchmaking a combination of mechanical ingenuity and organizing skill that we have since come to call mass production. It was clearly demonstrated in Philadelphia at the Centennial

Exhibition of 1876 that better watches could be made for less money by this revolutionary "American system," introduced by Aaron Lufkin Dennison in 1850 and developed by Waltham. The results were so spectacular that the methods were soon copied both at home and abroad, and eventually they were adopted as standard in the industry.

The first successful domestic competition came from the Elgin National Watch Company, which was founded in 1864. There followed a series of nearly 60 American firms which depended largely on domestic parts (except jewels) for the production of complete watches. Of these firms only Elgin, Hamilton, and Waltham remain.

In the early years of the industrial revolution, English methods of watch manufacture were the acme of manufacturing efficiency, but by 1850 they were fast becoming archaic. In that year Aaron Lufkin Dennison, founder of the Waltham Watch Company, visited England in search of technical information and reported as follows:

> "I found that the party setting up as manufacturer of watches bought his Lancashire movements—a conglomeration of rough materials—and gave them to A, B, C, and D, to have them finished; and that A, B, C, and D gave out the different jobs of pivoting certain wheels of the train to E, certain other parts to F, and the fusee cutting to G—dial making, jeweling, gilding, motioning, etc., to others, down almost the entire length of the alphabet."

He returned home convinced that competition with English firms would present no real difficulties to American watchmakers, if the latter used the interchangeable system and if manufacture on a large scale was adopted.

The interchangeable, or American, system, as it is called in the watch industry, was not originated by Dennison. He found it in a high state of development at the Springfield (Mass.) Arsenal, where it was used in the manufacture of rifles. The fundamentals of mass production had been employed by Eli Whitney (q.v.) in making firearms in 1798, and the system had been in successful use for over 50 years, when Dennison attempted to apply the same principles to watchmaking. It seemed obvious to Dennison that these mass production methods were applicable to the watch industry, but the sober judgment of the times was against him, and he was dubbed the "Boston Lunatic." There were, in fact, four major problems, the magnitude of which was not adequately foreseen. The seriousness of each problem was discovered separately, and each required a fresh start, one of them involving bankruptcy.

The first problem was to design a watch that could be produced efficiently by mass production methods. It was also desired to offer a conspicuous improvement over the watches then commonly in use, so that novel design would help to gain public acceptance for the product and the new method of manufacture. With these ends in mind, the first model produced by the Waltham Company was an eight-day watch having two mainsprings to furnish the additional power required for an interval of eight days with one winding. A few of these watches were made, but, as they did not keep good time, the model was promptly abandoned in favor of a standard 36-hour watch of the English lever type.

The second error was in design and construction of machine tools, sufficiently accurate for watchmaking and dependable enough as regards uniformity of output, for use in a mass production factory. Before the company was started, Dennison designed, built, and tested some of the key machines that were needed. Unfortunately the tests were not as exhaustive as the circumstances required, and the machine failed to meet the necessary standards of accuracy and uniformity. The machine-tool industry of that day had no equipment capable of such precision as four ten-thousandths of an inch when working on parts so small that a magnifying glass is needed to inspect them. It was therefore necessary to redesign the machines, to test and redesign again, until satisfactory accuracy and uniformity could be maintained day after day on many thousands of watch parts.

The tremendous capacity that is the great virtue of mass production requires that operations be conducted on a grand scale, and Dennison miscalculated the size of the undertaking. Having little capital of his own, he sought financial assistance from the Boston firm of Howard and Davis, and from Edward Howard's father-in-law, Samuel Curtis. With $30,000 obtained from these sources, the original firm attempted to mass-produce a watch containing approximately 150 parts and requiring some 3,700 distinct operations. The time and money required to bring such a venture to the point of profitable operation, and the ultimate size of the undertaking, were beyond the range of foresight. "It was more than three years," wrote Edward Howard, "before the establishment had fairly and fully started in the business of making watches, and then it was found that it would require ten times as much room as had been provided, and we set about building a very much larger factory." The new factory was built in 1854 on the banks of the Charles River at Waltham, Mass.

The most serious of the many problems facing the watch industry then and later was that of mass distribution, the Siamese twin of mass production. Little thought was given to marketing when the business was started. Both Howard and Dennison were widely acquainted in the jewelry trade, Howard as a manufacturer of clocks and Dennison through 10 years' experience as a wholesaler of watches in Boston. There was no difficulty in disposing of the output of the original plant in Roxbury, just outside of Boston, but when production in the new plant at Waltham reached 100 watches per month, marketing became the crucial function of the business. The need for wider markets came at a time (1857) when general business was in a state of severe depression. The problem of expanding the company's markets in the face of a collapse of general business activity put too great a strain on financial resources which had never been really adequate. As a consequence, the company went into bankruptcy and was sold at auction to Royal E. Robbins, a New York importer of watches.

The bankruptcy of the Waltham Watch Company throws dramatic emphasis on the hazardous nature of mass production. Four New England businessmen lost about $150,000 in the original Waltham venture, and Dennison failed three times more before he finally applied his ideas successfully to the manufacture of watch cases in Birmingham, England. The difficulties experienced in 1850 still handicap the efforts of businessmen in the use of these principles, and the number of failures in mass production industries is alarmingly high.

The chief causes of these failures are three

in number. To begin with, few, if any, complex products are mass-produced in their entirety; some parts can be made more efficiently by less highly mechanized methods. In 1863, Edward Howard wrote: "The interchangeability of parts, however, was found not to be practical in the finer parts; never has been to this day and never will be." This is the technical hazard in the use of mass production. Suppose, however, that automatic machinery *can* be used for most of the expensive operations, financial problems then become paramount. The purchase of so much intricate machinery calls for a vast outlay of funds, and it may require more money than can be attracted to the venture by the prospect of large profits. As the need for more and more capital develops, investors become reluctant to increase their contributions, and if profits are not promptly realized, the business is likely to die of financial strangulation. But even though the technical and financial problems are successfully solved, the enterprise may fail by reason of its own fecundity. The volume of output tends to increase with each rise in productive efficiency until it reaches unforeseen proportions and becomes a drug on the market. The venture then suffers that most common of all business disasters, failure in the field of marketing.

Marketing.—The production of watches by modern methods has been limited by the means for marketing them. Each improvement in watchmaking machinery and methods poured a new flood of watches on the market and forced the development of better and cheaper methods of distribution. The production of watches in the United States increased more than a thousandfold after 1854, and the resulting competition became extremely sharp. Only a few domestic concerns have been able to solve the problems of marketing on such a rapidly rising scale. In all, there have been more than 10 failures for every success in the American watch industry.

The machine tools used in the early years of the American system were an improvement over the standard English equipment in that they could be made to "repeat" the production of a given part easily and with great exactness. They were better machines, but they were not fundamentally different; the second major development —that of automatic machines—was accomplished gradually.

At first, automatic machines were frowned upon by management as well as workmen. Each machine in use required the entire attention of an operator, and the notion that a mechanical device could produce precision parts while the operator's back was turned did not seem practical. The first semiautomatic machines were therefore built and tested by Waltham inventors without the knowledge of management, but the results of the test were so remarkable that policy was reversed and subsequent developments were rapid. Even with the combined support of management and labor, the task of the inventors was a long one. The design of fully automatic equipment for multiple operations on plates and pinions was not completed until the last decade of the 19th century. Much of the best work in this field was done by Duane H. Church, who was employed by the Waltham Company from 1882 to 1905.

By 1879, the development of semiautomatic machinery had carried production at Waltham over 98,000 watches per year, and competitors—both domestic and foreign—were expanding their production by the same means. The market could not absorb so much at customary prices, and price cutting became common.

In addition to this, other efforts were made to expand the market without resorting to major changes in distribution methods. The appeals of variety and style were used in an effort to reach more customers and to stimulate repeat sales. There was also increased activity in foreign markets, particularly in Latin America, in England, and in the British Dominions. These measures were effective for the time being, but the continued improvements in production methods and the rising output kept an unremitting pressure on prices, and new economies were necessary. By 1910 a change in the channels of distribution could no longer be postponed.

The channels of distribution for watches prior to 1850 started with the foreign manufacturer, who sold to a domestic importer, from whom the watches passed to the wholesaler, the retailer, and the consumer. This method of selling watches entailed four separate business risks and four layers of expense and profit, all added to the cost of manufacture. Although this may sound cumbersome and inefficient, it was well suited to the distribution problems of that time. In fact, it stood the test of use for centuries. In 1910, however, the manufacturer's agent (who had replaced the importer when production started in the United States) was dropped by the Waltham Company from the chain of distribution. Thereafter Waltham watches were sold by the factory sales force direct to the jewelry wholesaler. The economies achieved in this fashion were adequate for a considerable period of years, but Swiss competition inaugurated changes both in production and distribution that called for further readjustments in the industry.

The Swiss were not slow to grasp the significance of the American system of watch manufacture, nor did they hesitate in dealing with this menace to one of their most important industries. Their first step was frankly to admit the facts. In 1876 one of the Swiss commissioners to the United States, Édouard Favre-Perret, addressed his countrymen most earnestly on the subject. He said in part:

> "For a long time we have heard here of an American competition, without believing it. The skeptics—and there were many of them—denied the possibility of a competition at once so rapid and so important. . . . I sincerely confess that I personally have doubted that competition. But now I have seen—I have felt it—and am terrified by the danger to which our industry is exposed."

Swiss producers rose to the occasion with changes in many phases of the industry. They were quick to seize the essential elements of the American system and put them to use. But they were not content merely to copy; they developed a new variation of the method that was particularly well suited to their conditions. Watch movements, produced wholly or in part in Switzerland, were shipped to the United States to be completed, sometimes merely to be cased. This arrangement had many advantages. It permitted a maximum use of Swiss labor at a very favorable scale of wages, yet made it possible to market these watches as a domestic product. It also permitted the Swiss to take advantage of any differential in tariff between completed watches and parts. Advances in Swiss merchandising also were notable, especially of the wrist watch which became popular about the time of World War I.

In the matter of watchmaking machinery Swiss designers were particularly successful.

The Swiss government was active in support of the industry. Measures were taken to prevent overproduction. Schools were established to ensure an adequate supply of skilled watchmakers and designers. The watch industry of the nation was organized into a trust for large producers and a superholding company for smaller manufacturers. Through these organizations the Swiss government was able to take such measures as seemed desirable for protecting interests of the industry.

The aggressive efforts of the Swiss were so successful that imports of watches, movements, and materials from Switzerland into the United States exceeded $12,000,000 in 1929, but countermeasures were soon forthcoming. The Smoot-Hawley Tariff Act, passed by the United States in 1930, sharply reduced Swiss imports. The higher tariffs, combined with the depression in general business, carried Swiss imports of watches and parts down to $1,300,000 in 1932. Unfortunately for the American industry, the official figures on imports did not represent the true total; smuggling (judging by the newspaper reports and the court records) was a thriving industry. One American producer estimated that smugglers brought in between one and two million movements per year.

In the attempt to increase sales, Swiss ingenuity turned to devices for expanding the market as a whole. Manufacturers with Swiss affiliations were particularly active in radio advertising; one firm is reported to have spent $1,250,000 in 1937 on this form of advertising alone. Sales by the factory direct to retailers, and extensive consumer credit, were also employed to facilitate the rapid flow of watches to the widest possible market at the lowest possible price. These practices have been adopted by some of the old-line American producers, illustrating again the vigorous give and take of international competition. On the whole, progress in the marketing of watches has lagged behind production, and further substantial improvements in marketing methods are to be expected.

The watch industry as it existed just prior to World War II was largely confined to Switzerland and the United States (See U.S. Tariff Commission, *Watches,* pp. 3-6, Washington, 1946). There were then four producers of essentially complete jeweled watches of quality in the United States: Elgin, Hamilton, Waltham, and the Bulova Company. The Bulova Company was also an importer of Swiss movements and an assembler of Swiss parts. About 100 other firms fell in the class of importers and assemblers. In Switzerland there were 68 manufacturers of complete watches and 350 assemblers. In 1941 domestic manufacturers had about 38 per cent of the United States market, the remainder going to importers and assemblers of Swiss goods. Exports of the Swiss watch industry to the United States were from 10 to 27 per cent of the total value of all Swiss exports.

War Production.—M. Favre-Perret sounded the keynote of past rivalries in the watch industry, when he referred to the American market as the "milch cow" of the Swiss producers. In the future, however, military necessity will be added to the economic motives that have driven international competition at such a hard pace. It is even conceivable that national survival may hinge on the existence of a large and thriving domestic watch industry.

War has always been a stimulus to the American watch industry, but it was not until World War I that its essentially military character began to appear. During that conflict the government's demand for watches grew with the increasing importance of precise timing and coordination in military operations. At this point, also, there arose a demand for a new class of product, not directly related to watches, but requiring the same unique skills and the same, or similar, equipment. The first of the strictly military products of the watch industry was the time fuze for controlling the burst of shrapnel. This item was developed and produced—in cooperation with the government—at the Waltham plant during World War I. As the tools of war have become more intricate and powerful, the devices for controlling them have become more numerous, more delicate, and more precise; as the scope of war expands, the need for mass production becomes imperative. Productive capacity for a large volume and variety of precision parts is essential to military preparedness.

In World War II the entire watch industry was mobilized. The tremendous increase in the number of tanks, aircraft, and naval units established a new peak in the demand for military watches, especially the precision models for use in navigation. In addition to watches, chronometers, and small clocks, the industry produced a wide variety of precision parts and equipment. The line of fuzes was expanded to include percussion and base-detonating types. Other items in the list of war material were tachometers, speedometers, compasses, recording drift sights, precision springs, and rifle parts. Exact figures on the value of the munitions turned out by the watch industry during World War II are not available at the time of writing this article (1947), but the total has been estimated at between 100 and 200 million dollars. This figure, large as it is, does not give a true gauge of the importance of the industry to military operations. The items produced are vital to the navigation of ships and planes, to the effective operation of tanks, to the control of burst of heavy projectiles, and to a host of minor uses where timing is the essence of successful action.

It is customary in the United States to think of war production as infinitely expandable by converting peacetime industries. This has been approximately true, but the capacity of the watch industry is limited by the number of skilled workers. The peacetime force cannot be augmented by newly trained workers within the time permitted by the pattern of modern war. For example, it requires an average training period of one year to produce a fully skilled machine operator, and six years to train a die maker. Experienced finishers who assemble the components and adjust the finished mechanism need three years to become masters of their trade, and so on through the wide variety of special skills which require training and experience not provided in other peacetime industries. Carefully planned training programs were arranged by the industry with the cooperation of the government during World War II, but such programs are of limited value unless there is a large force of fully trained workers to carry on the conversion of equipment from the production of civilian goods to the manufacture of military items. At best, it

requires one to two years to develop and to put into production a new military watch or similar device.

Labor Relations.—The workers of the watch industry as a whole have been doubly fortunate: first, in the liberal policies of the watch companies, and second, in the exceptionally able leadership displayed by their union organizer. With the growth of the Waltham Company some of the personal contact between management and the workers was lost, as was the case in most other industries. Under these circumstances the organization of the employees into a labor union was a logical development. In 1941 an organizing campaign was successfully conducted at Waltham under the auspices of the American Federation of Labor (AFL). The union subsequently retired from the AFL and set up an independent Watch Workers Union, extending the organization to include the employees of the Hamilton and Elgin companies.

The union has shown a sound regard for the difficult business problems of the industry, and has avoided the use of tactics that impede the successful conclusion of collective bargaining. Good relations have been further promoted by a temperate and cooperative attitude on the part of management. Industrial peace has been maintained through the reconversion period following World War II, in spite of the controversial issues arising from wartime inflation and Swiss competition. In regard to foreign competition and its effect on employment and wages, the union is exerting its major pressure on Congress for the raising of import duties on watches. The government must balance the advantages of a brisk foreign trade with Switzerland against the requirements of national security and domestic prosperity in the watch industry. See also Clocks.

Charles W. Moore.

WATCHUNG or **ORANGE MOUNTAINS,** in New Jersey; a range of hills west of Paterson, Plainfield, and Orange, extending north and south, but curving westward at each end. Length, about 40 miles. There are three divisions of the range, each composed of trap-rock, which was a lava flow about the time other portions of New Jersey were in a more advanced stage of formation. The mud and sand covering followed and now the ranges are mostly shale and sandstone. The traprock, in places, forms elevations from 300 to 400 feet high; the soft sedimentary beds once enclosing it, yielded more rapidly to erosion. There is a similarity in the material composition of the Watchung Mountains and the Palisades, the difference being more in the direction of the original lava flow. The Palisades sheet was not a surface flow, but was forced between the sedimentary beds.

WATELET, vä-tê-lā′, **Claude Henri,** French writer and artist: b. Paris, 1718; d. there, 1786. The son of a receiver general of finances for the Orléans district, he succeeded his father in that office, but continued to cultivate a taste for painting, sculpture and engraving. He obtained admission to the Académie Française through his authorship of a didactic poem, *l'Art de peindre* (1760). He built a charming country place on the banks of the Seine, naming it "Moulin-Joli." Its grounds became the classic model of "English Gardens," so much in vogue in France in the epoch just prior to the Revolution. His *Essai sur les jardins* (1774) helped considerably toward popularizing landscape gardening. He also compiled a dictionary of painting, engraving, and sculpture, published posthumously in 1792.

WATELET, Louis Étienne, French painter and lithographer: b. Paris, 1782; d. there, 1866. Commencing his career in 1799, his first canvasses were tritely traditional landscapes with the usual ruined castles. During the decade 1810–1820 he tried to escape the trammels of convention in several French and Italian views. Later he followed the romantic movement. Among his best works are *Lac Némi, Canal près de Bruges, Terrasse à Richemond,* and *Vue d'Inspruck.*

WATER, a universally diffused liquid, the true nature of which was not discovered until toward the close of the 18th century. In 1781 Henry Cavendish carried out a series of experiments by detonating mixtures of common air and hydrogen or dephlogisticated air, as it was termed. He showed that by regulating the relative quantities "almost the whole of the inflammable and dephlogisticated air is converted into pure water." Although Cavendish showed experimentally that water is produced by bringing together oxygen and hydrogen, yet to Antoine Lavoisier, who received information regarding Cavendish's experiments, must be assigned the merit of interpreting aright the experimental results, and of proving that water was a compound substance—a compound of hydrogen and oxygen.

Water may be produced by exploding a mixture of two volumes of hydrogen with one volume of oxygen at a temperature above 1190° F. Below that temperature the gases will not unite. It may also be produced by passing hydrogen over the heated oxides of several of the metals—and in various other ways. It exists, although never in a perfectly pure state, in immense quantities in nature. The composition of water has been determined by two distinct methods: (1) by volumetric synthesis; (2) by gravimetric synthesis. In volumetric synthesis of water measured volumes of pure dry hydrogen and of pure dry oxygen are mixed and the mixture is exploded by the electric spark while standing over mercury; the residual volume of gas is then measured; it is found that two volumes of hydrogen invariably unite with one volume of oxygen. In the second method a weighed quantity of a metallic oxide (usually cupric oxide) is decomposed by means of pure dry hydrogen at a high temperature and the water which is produced is weighed. The decrease in weight of the oxide gives the quantity of oxygen in the water formed; while the difference between the total weight of water and the weight of the oxygen gives the weight of hydrogen used. It is found that 16 parts by weight of oxygen are always united with two parts by weight of hydrogen to form 18 parts by weight of water. In the scale in which 16 is adopted as the atomic weight of oxygen the formula of water is H_2O. The molecular weight of water has been variously

decided upon; first as 18, later as 36, and it is now accepted as probably 72.

Water is a tasteless, inodorous liquid, under usual conditions, colorless; but when a great thickness of it is examined, as in looking endwise through a pipe filled with it, it is found to have a distinctly blue tint. At all temperatures below 32° F. it is a solid and at all temperatures above 212° F. it is a gas. When water at 32° is heated it contracts until it reaches the temperature of 39.2°, after which it expands; conversely, when water at 212° is cooled it contracts until it reaches the temperature of 39.2°, after which it expands; 39.2° F. is called the point of maximum density of water; the specific gravity of water is greater at this than at any other temperature. The fact that water expands on cooling from 39.2° to 32° is a most important one. If a sheet of fresh water be cooled, the upper layers become more and more dense; they, therefore, tend to sink, and so fresh surfaces are exposed to the cooling influences. But when the temperature of the mass of water has reached 39.2° further cooling of the surface causes an expansion of the upper layers, which continues until these solidify into ice; these layers of cold water consequently float upon the warmer water underneath; hence it is impossible for the mass of water to suddenly freeze throughout. When water passes from the liquid to the solid state it expands to the amount of about 1-11th of its volume; that is, one volume of water forms 1.0908 volume of ice. This expansion is sufficient to bring about a large quantity of mechanical work, and to it the bursting of water-pipes during frost is to be largely traced. When solid water becomes liquid, or when liquid water becomes gaseous, a considerable quantity of heat is absorbed and disappears, or, as the expression is, is rendered "latent" Steam issuing from boiling water is no hotter than the water itself; water formed when ice is melting is no hotter than the ice itself; yet heat is being communicated to the ice and to the water. The latent heat of water is 79 thermal units; the latent heat of steam is 536 thermal units, although by the thermometer the temperature remains unchanged. In other words, in order to convert unit weight of ice at 32° into water at 32° a quantity of heat must be communicated to the ice, which, if communicated to unit weight of water at 32°, would raise its temperature to 79° C. In order to convert unit weight of water at 212° into steam at 212° such a quantity of heat must be communicated to the water as would suffice to raise the temperature of that weight of water through 536° C., or 536 times that weight of water through 1° C. Before water can become steam the upward pressure of its vapor must overcome the downward pressure of the atmosphere; hence it follows that the boiling point of water is conditioned by the atmospheric pressure. Water boils at a much lower temperature on mountain tops, where the pressure is comparatively small, than in the valleys. Water is almost incompressible. At 32° it is diminished in volume only by the fraction .0000462 for each atmosphere (14.7 pounds) of pressure added.

The solvent power of water is very large. As a rule hot water dissolves larger quantities of solid matter than cold. Water is found in nature in many forms — vapor, dew, hoar-frost, rain, hail, snow; besides the several distinct variations of spring water, well water, river water, surface water, sea water, etc. As has been mentioned it is never found in a state of purity. Analyses of dew and hoar frost show from 2.64 to 8.00 parts of solid impurities in 100,000 parts of water. These are organic carbon, organic nitrogen, ammonia, nitrates and nitrites, chlorine, lime and magnesia. These substances have been held in solution in the vapor of water in the air. Snow will gain in ammonia content the longer it lies on the ground.

Rain water, when collected before it touches the earth, contains only such impurities as may be derived from the atmosphere, chiefly consisting of oxygen, nitrogen and carbon dioxide, with more or less nitric acid and ammonia in the case of thunder showers. The rain water of towns contains comparatively large quantities of sulphurous and sulphuric acids and of soluble salts. The amount of these substances may be taken as an estimate of the comparative purities of the atmospheres of different towns. Rain water collected near the sea is rich in chlorides. Samples of rain water taken in a farming country near the sea have shown 42.8 parts of solid impurities per 100,000.

River water varies greatly in so far as the nature and quantity of the substances held in solution by it are concerned. The soluble constituents of river water are chiefly such as may be derived from the rocks through which the water of the springs which have fed the river has percolated and the amount of surface water it has received owing to storms. The dilution of the original spring water by the continual influx of tributaries reduces the relative quantity of solid matter held in solution, while the escape of carbon dioxide during the exposure of the surface water to the air causes the precipitation of those salts which were held in solution by the aid of the carbonic acid. River water is often largely contaminated by the drainage of towns or of manufactories situated on the river banks.

Spring Waters.— The soluble constituents of spring waters are various. In some springs the quantity of dissolved solid matter is but trifling, while in others it amounts to 2,000 grains per gallon. Spring waters are usually divided into classes in accordance as one or other dissolved constituent predominates. See MINERAL WATERS.

Sea water is essentially an alkaline chlorinated water. The quantity of solid matter held in solution varies in the waters of different seas. Inland seas, as a rule, contain less solid matter than the ocean; thus the solid content of the water of the Black Sea amounts to about 1,760 parts per million, while that of the Baltic averages 17,700, and that of the Atlantic Ocean 36,000 parts per million. The substances held in solution in sea water are chiefly chlorides and sulphates of sodium, magnesium and potassium, together with iodides, bromides and carbonates, chiefly of potassium and calcium.

Use of Water.— In considering the suitableness of a water for domestic use attention should be principally paid to (1) the source of the supply, (2) the total solid matter held

in solution by the water, (3) the organic matter held in solution and (4) the action which is likely to be exercised on the water by the means of supply. In examining the source of a water supply attention should be paid especially to the proximity of drains or sewers of any description, and to the likelihood of contamination from these sources. The nature of the soil through which the water percolates should also be inquired into. The solid substances held in solution by a sample of water may be estimated by evaporating a measured quantity of the water to dryness in a platinum basin heated by steam and weighing the residue. From a knowledge of the total solids in a water, unaccompanied by any further information, no reliable conclusion as to the suitability of such a water for potable purposes can be deduced. In seeking to determine whether a sample of water has undergone contamination with hurtful organic matter the following points are to be more particularly attended to: (1) Estimation of the amount of chlorine, whether existing as hydrochloric acid or as a chloride; (2) estimation of ammonia; (3) estimation of nitrates, and (4) detection and estimation, if necessary, of poisonous metals. The presence of an undue amount of chlorine generally points to contamination with animal matter. Pure waters do not as a rule contain more than three to four grains of chlorine per gallon. It must, however, be borne in mind that such waters as flow through a soil rich in chlorides — such, for instance, as the waters found in the neighborhood of salt-beds — always contain large quantities of chlorine. The sudden appearance of chlorides in a water previously free or nearly free from these substances points to animal contamination.

Ammonia may be obtained from most waters by distillation after the addition of a little sodium carbonate; when the whole of this ammonia has been driven off it not unfrequently happens that the addition of an alkaline solution of permanganate of potassium and heating results in the production of a further quantity of ammonia. The ammonia obtained by the first distillation is usually spoken of as "free ammonia," while to that obtained by the second distillation the name of "albumenoid ammonia" is given. The presence of even small quantities of albumenoid ammonia points unmistakably to organic contamination. Such ammonia is derived from the decomposition, by the agency of the alkaline permanganate liquid, of nitrogenous matter of animal or vegetable origin. Pure water should not contain more than 0.10 parts of "free" ammonia per million, nor more than 0.08 parts of "albumenoid" per million.

If nitrogenous matter has become thoroughly oxidized it gives rise to the formation of nitric and nitrous acids. The presence of these acids or of their salts, therefore, generally points to previous contamination of some organic nature. As, however, these things are the harmless — that is, in the quantities in which they occur in waters — products of the decomposition, and, therefore, of the removal, of hurtful substances, their presence, even when in comparatively large quantities, ought not of itself to condemn a water. The poisonous metals which are most likely to occur in drinking waters are lead and copper. These may be easily detected and estimated even when present in exceedingly minute quantities. For details of the analytical methods of water analysis reference must be made to manuals of applied chemistry. It is evident that in a water analysis we look for symptoms of a disease; not for substances which are in themselves hurtful, but for substances whose presence is associated more or less invariably with others, the action of which upon the system cannot but be pernicious.

In storing water for domestic purposes the water may undergo contamination from the vessels containing it or from proximity to drains or other places emitting noxious gases. It is certain that water exercises a solvent action upon lead; but our ordinary leaden water pipes and tanks become coated with a comparatively insoluble compound of lead, so that the danger of contamination from this source is not great. Hot water should never be stored in leaden tanks; it very quickly corrodes and dissolves the metal. Aerated waters act rapidly on lead: for this reason they should never be prepared or stored in leaden vessels. The solvent action of water on copper is very small. The system of storing water for drinking or cooking in cisterns close to, or even communicating with, the house drainage system, is a very bad one. (See SANITARY SCIENCE; PUBLIC HEALTH). In some circumstances, as in the case of swimming-baths, large quantities of water have to be heated to a certain temperature and kept at the same for a considerable time while the water has to be maintained in a due condition of purity. For industrial purposes also most waters require purification of a kind, depending upon the processes of manufacture in which they are employed. The most common treatment is that known as "softening," for the removal of lime and magnesia carbonates, chlorine and other lesser impurities. See WATER SOFTENING; WATER SUPPLY.

WATER, ITS RELATION TO DISEASE. See WATER SUPPLY.

WATER BABIES, The. This story, by Charles Kingsley, written originally for the amusement of his youngest son "and all other good little boys," and published in 1863, remains perhaps the most popular of the author's works, with the possible exception of the historical novel 'Westward Ho.' It is on the face of it a fairy story. Tom, a little friendless chimney sweep, falls asleep in a fine house where he is working and is transformed into a water baby, being in most respects like a land baby, except for the presence of gills and other necessities of aqueous life. As a water baby he has many charming and attractive adventures of the kind since made more popular as well as more fantastic through Lewis Carroll's 'Alice in Wonderland.' In addition to these merely odd happenings, the book is, characteristically, a treatise on belief and education. As in 'Alton Locke,' 'Yeast,' 'Westward Ho,' 'Hypatia' and other Kingsley novels, there is a fundamental moral thesis. In this book it is that one must not be too prone to dispute the existence of this or that simply because he has not seen it. This idea comes out most clearly in the clever argument of Kingsley's to demonstrate the existence of water babies. From this

point of view the book is a vivacious argument for faith, designed on the one hand to make readers less assertive and dogmatic and also to render them more receptive of the underlying, if undemonstrable, mysteries of the Christian religion.

WILLIAM T. BREWSTER.

WATER BALANCE, an oscillating pendulous frame, having a series of troughs in vertical series and inclined in alternate directions, so that, as the frame oscillates, the water dipped by the lower one shall be poured into the next above, which, on the return motion, shall pour it into the next, and so on.

WATER BAROMETER. See BAROMETER.

WATER-BEARS. See TARDIGRADA.

WATER BED, a watertight mattress or bed for relieving any partial pressure of the body of a patient long confined to bed and so preventing the formation of ulcers which arise from such local pressure. One form is that of a trough half-filled with water, covered by a loose lining of india-rubber sheeting attached all around to the upper edge of the trough so as to be watertight, a mattress being laid between the invalid and the lining. Another form is that of a large waterproof bag which is laid upon an ordinary mattress and half-filled with water, the weight of the body resting upon this directly or with bed clothes between.

WATER-BEETLES, the numerous species of beetles which inhabit water. A common mode of life does not indicate blood relationship, and the various aquatic beetles belong to a number of quite distinct families. Besides those which are aquatic throughout their lives quite a large number of beetles live in or near the water only during the larval period. The strictly and permanently aquatic beetles belong chiefly to three families. The diving beetles (*Dytiscidæ*) are predaceous throughout life and represent in the water the *Carabidæ,* to which they are somewhat closely related, on land. The legs in these insects are adapted for swimming, the two hinder pairs being flattened and fringed with hairs. The body is oval and flattened. The mandibles are short and strong and the thorax is broad. The front legs are short and the antennæ long and filiform. In the genus *Dytiscus* the tarsi of the males are wide, flat and provided with sucking discs, while those of the females are unmodified. The females are of two forms, the one having the wing-covers smooth, the other grooved. The head is short and received into the thorax. *D. fasciventris* is the common water-beetle of our ponds. These insects carry a supply of air for breathing beneath the *elytra* or wing-covers. At evening they fly in the air. They are eminently carnivorous in habits and feed on other insects. The larvæ are active creatures and are also aquatic; their noteworthy rapacity has gained for them the name of water-tigers, which they well merit, for they will not hesitate to seize in their sharp sickle-like jaws any insect-larvae, small fish or tadpole that comes within reach, and after draining its juices discard the dead body. The tail is terminated by a pair of respiratory tubes which are raised above the surface of the water to effect respiration. Besides this large species the family includes numerous small ones having similar habits. The other two families have club-shape instead of filiform antennæ.

The *Gyrinidæ,* or whirligig beetles, have the antennæ short, the front legs long, clawed, and in the males provided with a spongy disc, the second and third pairs of legs very short, broad and paddle-shaped, and the elytra do not cover the tip of the oval body. They derive their familiar name from their peculiar habit of describing circles on the surface of the pools they inhabit. When alarmed these insects dive to the bottom and anchor themselves for a time by means of the strong front legs, carrying with them a small bubble of air on the tip of the abdomen. Owing to their smooth, polished and oily surface they are unaffected by the water. The facets of the compound eyes are divided into two groups on each side, one adapted for vision in the water, and looking downward, the other for looking upward in the air — an important adaptation to the peculiar mode of life of these insects on the surface. When handled, the whirligigs emit from the joints a peculiar strong-smelling milky fluid. Although, like the *Dytiscus* larvæ, the young of the whirligigs are predaceous, their appearance is totally different; they are of slender form and, instead of a single pair of caudal respiratory tubes or gills, they bear 10 pairs of fringed lateral gills on the sides of as many abdominal segments. Several other genera and species are common in ponds.

The largest of the common water-beetles belong to the family *Hydrophilidæ,* which also includes numerous small and inconspicuous species. In the form of the body and the fringed oar-like middle and hind legs they resemble the *Dytiscidæ,* from which all the members of this family are distinguished by their short strongly-clubbed antennæ. The eggs are deposited in silken cocoons attached to water-plants or carried by the female. In general resembling the water-tigers in form, the larvæ have shorter, thicker, solid jaws, much less prominent respiratory tubes and are less active, although, like them, carnivorous. They pupate in burrows in the banks of the ponds which they inhabit. The great water-beetle (*Hydrophilus triangularis*) is a pitchy black polished beetle an inch and a half long, often seen flying at night or during the day rising to the surface of clear weed-grown ponds for air and, unlike the *Dytiscidæ,* usually resting head upward. In adult life they forsake the predaceous habits and animal diet of their larvæ and become scavengers, finding their food chiefly in the vegetable debris at the bottom of ponds. Few inhabitants of fresh-water ponds and ditches are better suited to life in an aquarium than these beetles and few present a greater variety or more interesting habits. Consult standard works, especially Miall, 'The Natural History of Aquatic Insects' (New York 1895) and Morgan, A., 'Field Book of Ponds and Streams' (1930). See FRESH-WATER INSECTS.

WATER-BOA, the anaconda snake. See BOA.

WATER-BOATMAN. See BOAT-FLY; WATER-BUG.

WATER BRASH. See PYROSIS.

WATER-BUG, an aquatic bug of the hemipterous family *Notonectidæ*. The hind legs are long and adapted for swimming by being provided with a fringe of stiff hairs. The body is prismatic in form, convex above and flat beneath, and the head is as large and as wide as the body. *Notonecta* is the typical genus of the family and *N. irrorata* and *undulata* are two of the common species. These and others abound in ponds and streams, where they rest on their backs at the surface, occasionally striking out with a vigorous oar-like movement of the hind legs, or dive to the bottom and cling to plants or stones. They are constantly buoyed up by a film of air which surrounds the abdomen, partly entangled in a coat of close fine hairs, partly held between the wings and the abdomen in a space into which the spiracles open and partly between the joints of the abdominal and thoracic segments. On land the water boatman are at a disadvantage and progress by a series of spasmodic leaps; but they are agile fliers. As larvæ, nymphs and imagoes they are predaceous and, besides strictly aquatic insects, young fishes, etc., they attack and suck the juices of flying insects which happen to fall into the water or approach its margin to drink. Various other hemipterous insects, such as the water-scorpions (q.v.), are aquatic. The croton bug is not truly aquatic, but is called a water-bug because it frequents water-pipes in cities.

WATER-CLOCK. See CLEPSYDRA.

WATER-COLOR. See PAINTING, TECHNIQUE OF.

WATER-COLOR PAINTING, in contradistinction to oil painting, the use of water generally interfused with gum arabic as a vehicle for applying colors, very often transparently, to a white surface. Anciently, there were three distinct methods of water-color painting, and these were known as tempera, encaustic and fresco. Tempera, or as it was sometimes called, distemper painting, was common in early Italian art. (See PAINTING). The colors were ground and mixed with the beaten-up white and yolk of an egg, or with the white juice of the fig tree, and sometimes with ox-gall. Encaustic painting was a process in which the colors were mixed with wax and laid in a thin coating, then fixed by the application of hot irons. The early Flemish and Dutch painters attained considerable success by the use of water colors in the medium of tempera, long previous to the invention of oil painting by the Van Eyck brothers. The Italian frescoes are painted in water color, on damp plaster and have retained their colors scarcely impaired for centuries. See FRESCO PAINTING.

But when we speak of water-color painting in a modern sense we refer to the aquarelle. The ancient Egyptians used water-color to decorate their papyrus rolls, and the monks of the Middle Ages employed it to adorn vellum manuscripts; but this was all impasto, not the transparent washes, as in modern English work. This process and manipulation was the outgrowth of the methods worked out by Paul Sandby (1725–1809) and advanced by Alexander Cozens, creating an entirely new type of fine art productions known as aquarelles. The former treatment of the water-color work on white paper was really a species of sketching in outline certain scenes then filling in the spaces with water-color (color printing). In the aquarelles the brush supersedes the pen (or pencil). Thomas Girtin (1775–1802) perfected the method and produced pictures disclosing consummate genius, and the novel charm of light and shade in nature as a fine art with transparent washes was revealed to admiring connoisseurs. These were the precursors of a talented English school. In the English school there has been no exclusive use made of what is known as body color. The lightness and darkness of each tint have generally been determined by the degree of their dilution with pure water, not by their modification through an admixture of Chinese white.

In early painting the pigments employed were generally mineral earths or juices pressed from plants. The colors found in antique frescoes were few but permanent in value. In the Middle Ages chemistry came to the aid of the fresco painter and supplied him with many brilliant and permanent tints, which is some instances vied with the lustre with which the church window maker stained his glass. The modern water-color painter has gained innumerable additions to the color range of his palette, and the freshness, crispness and unerring certainty of his touch have been largely due to the beauty, clearness and permanency of the colors in which he has worked. Manufacturers have, indeed, vied with each other in providing him with pigments which shall flow smoothly from his brush and stand projected with nature's beauty upon his paper. While the modern water-color painter aims at producing his effects by means of transparent washes, artists have not always considered it illegitimate to resort to the use of body color in their efforts to impart to their work the depth and solidity of oil painting.

Technique.— The necessary apparatus of a water-color artist's studio is simple and consists of paper, drawing-board and drawing-pins (push pins), palette pigments and brushes. Many use an easel, but a number rest the drawing-board on their knees or on an adjacent piece of furniture (table, etc.). To avoid the paper from crinkling or cockling when the water washes are applied it is necessary to stretch the paper, by wetting it with water and fastening it firmly to the board by pins or mucilage around the border. While there are differences of opinion as to what paper to select, there is a limit to the number of makes acceptable to any artist. All used surfaces, grains, textures, etc., are comprised in the following list: Whitman, Allenjé, Michallet, David Cox, Creswick, Varley, cartridge, Van Gelder, white Canson and Burlington.

Pigments.— The colors used by the early aquarelle masters were made up into little hard bricks (cakes) and were rubbed out in water on a porcelain surface, but a more recent, perhaps more convenient, form of pigment preparation consists of moist colors, requiring less manipulation before being ready for the brush. Light-red, yellow ochre, cyanine blue, ivory black and burnt sienna are the colors which are the mainstay of artists. From these basic pigments can be produced every ordinary color effect in nature directly or by blending. But, in these days of rapid action, many or most artists add an

array of other paints to the color-box, care being taken that they are not such as fade quickly in the light, as do prussian blue, antwerp blue, etc. French ultramarine (pure ultramarine being altogether too expensive), Indian ink, rose madder, sepia, oxide of chromium, vermilion and naples yellow are considered safe for use. Brushes are peculiarly a matter of choice of individual artists, their sense of touch differing greatly. The number selected is not so much a matter of importance as their being kept *absolutely* clean and carefully dried after use.

But the full capacity of the water-color medium was not known before the pictures of Joseph Mallard William Turner (1775–1851) (an early student of John Cozens' works and a constant coworker with Girtin till the latter's premature death), were exhibited to the world. His early water-colors were, indeed, low in tone and gloomy, though forcible and convincing. What he came to do in the way of color is shown best in his Venetian studies, originally made on the spot in water-colors. Turner, however, did not confine himself to the water wash; when he thought it necessary he employed body color in parts of his work, and even, on occasion, pastels; or it may be pencil or pen. But he never revealed to anyone the secrets of a technique which made him the greatest landscape painter in water-colors which the world has ever seen. The foundation of the Old Water-Color Society, in 1800, and of the new society, in 1863, gave a great impulse to the art, among whose representatives may be mentioned Copley Fielding (d. 1855); Peter de Wint (d. 1849); Samuel Prout (d. 1852), the master of architectural painting; David Cox (d. 1859) and the brilliant executer of Oriental genre, Lewis (d. 1876). Taylor and Landseer, as animal painters, found this a successful and pliant medium, and among the Pre-Raphaelites who were eminent aquarellists may be mentioned Rosetti, Madox Brown, Burne-Jones, Holman Hunt and Millais.

Prominent Aquarellists.—A partial list of the aquarelle artists of the English school whose works are appreciated by connoisseurs at sales must include the following; there are, of course, a number of noted artists who use the water-color medium as a side issue for «studies» but do not specialize on aquarelles. Earliest masters: Alexander Cozens and his son John Robert, Girtin, Turner, De Wint, David Cox, J. S. Cotman, Copley Fielding, S. Prout, Devis, Hearne, Bonington, Rooker, the two Cleveleys, W. Payne and N. Pocock. Belonging to the latter half of the 19th century we have F. Walker, G. J. Pinwell, Sir John Gilbert, G. Cattermole, E. J. Gregory, M. Birket Foster, J. M. Swan. Recent artists: R. W. Allen, Mrs. Allingham, Wilfrid Ball, F. Brangwyn, Sir Alfred East, G. S. Elgood, W. R. Flint, A. Goodwin, A. Ingram, F. E. James, H. Marshall, E. Noble, A. Powell, A. Rackham, A. Wardle, Sir E Waterlow, J. R. Weguelin, J. W. West, M. Fisher, M. Hale, Hughes-Stanton, Lamorna Birch, A. W. Rich, C. M. Gere, C. J. Holmes, etc.

In France, among able landscape painters in water colors, were conspicuous I. B. Isabey (1767–1855); Hubert, J. Ouvrié, Sué and Fort. They pretty generally employed body color (*gouache*) in their composition, the transparent wash being much less frequently employed in France. In portraits, Olivier Grand; in flower painting and still life, Redonté (1759–1840), the best painter of this class France has ever produced. But the art was not tried to its full capacity until the oriental sketches of Eugene Delacroix (1798–1863) proved to the French art world that there was something to be sought for fresher and more inspiring than the frigid classicalism of David. His lead was followed by Descamps (1803–60), one of the best colorists and most original painters of the modern French school, who taught his countrymen that it was possible to represent in water-colors the broad blaze of open sunlight in an African sand-plain; or in the streets of Smyrna and Constantinople. The powerful genres of Gavarni (1804–66) made a sensation even in England, the native home of water colors.

The German school of water-color painting began with the illuminating or tinting by hand of copper plate engravings. An independent and distinct department of aquarelle came late in the history of German art. The first notable aquarellists in that country were Karl Werner of Leipzig and Edward Hildebrandt of Berlin — Viermann, Otto, Grael of Berlin, Heindrich, Stöckles, R. Stieles of Munich and a circle in Düsseldorf, including Scheuren and Mintrop, kept up the traditions of German water-color painting. A new path was struck out by Menzel, who obtained a great following. He adopted a broad, frank and dashing style which was much admired. The Berlin painters, such as Franz Skarbina and Paul Mayerheim, vied with him in this method of handling. But German aquarelle has never been distinguished for the lightness of touch, the brilliant and transparent coloring, the powerful and vivid landscape effects which we find in the productions of English and French artists. Italy and Russia on the other hand have many skilful adepts in this art. The vivid coloring of such masters as Corelli, Zezzos and Mainella has a light and vividness all its own and the creations of these painters are worthy of comparison with many of the most eminent workers in their own department of art in other parts of Europe. The same may be said of the Russians, Benkendorf, Bergholz, Karafin, Heftler, Jegornow, Pissemski and Ehrenon.

Water-color painting has always formed a very living section of American art life. When Vassili Verestchagin, the great Russian war painter, was in America, he was astonished, according to his own account, that native artists were not more alive to the possibilities of American scenery and American life as subjects for the pencil. He was not sufficiently acquainted with the history of art in the country to which he had come a stranger, to be aware of the fact that local art had long flourished there. The Hudson River School of painters produced many noble transcripts from the scenery of that river, mostly in large canvases, and by employing oil as a favorite medium, but several of them have also executed gems of art in water-colors after the style of the best masters. Among those who have done some good water-color sketching among the sublime scenery of the West may be named Albert Bierstadt, some of whose views are correct in drawing and rich in coloring, albeit they owed their original impressiveness to the novelty of the effects in atmosphere and moun-

tain contour or coloring which they reproduced. The same in a less degree may be said of the drawings of F. E. Church. Neither of these painters was, however, as triumphant in water as in oil. The New York Water Color Club has done much to foster a revived interest in this most difficult yet most effective and delightful department of the painter's art and among the most successful of those who cultivate it may be enumerated James McNeill Whistler, John Singer Sargent, Childe Hassam, Abbey, Moran, Parton, Murphy, Parsons, Shurtleef, Tryon, etc. Louis C. Tiffany is a colorist of rare gifts and although his natural predilection leads him to the representation of still life, yet his water-color landscapes have a value of their own. Charles Sanderson is well known for his lovely water-color studies of the shores of Lake Michigan. At the end of the 19th century there was suddenly a new movement developed in this department, principally through the influence of John H. Twachtman, whose early death was a sad blow to the cause he had most at heart in his native country. In 1898 the Ten American Artists crystallized into a new school of painting in New York. As far as this movement was represented by Twachtman it stood for a distinct advance in water-color art. There can be no doubt that he reflected in the practice of his art the very best features of that style which in Europe was embodied in the work of Girtin, Cozens and Turner. Water-color painting in the United States numbers among its devotees many other great names. Homer D. Martin's few water-colors are of the highest value. Frederic Crowninshield shows in his water-colors a noble sense of the form of hills and cliffs and the greater forms of the landscape, as well as of tree-form. Winslow Homer's many water-colors are about as important a contribution to American art as any other group of works. They are extremely vigorous and impressive, they sell at high prices and among lovers of modern painting there are certainly none more esteemed. Winslow Homer is essentially a «painter's painter» and no single artist in the whole group is more admired by his fellow-artists. John La Farge's water-colors are what have chiefly made his great reputation. There are hundreds of them in private collections in Boston, New York and neighboring towns and the show of the South Sea Island collection at the Paris Salon in 1898 or 1899 occupied a hall especially set aside for it and made a great sensation. There is nothing in modern art more rich in color than these La Farge drawings, which were produced during the years 1865 to 1895 chiefly; for from that time he became thoroughly absorbed in decorating work, glass and the like. The work of Robert F. Blum and that of Irving R. Wiles commands the admiration of their brother artists. Francis Hopkinson Smith was a master of loaded color, that which is mixed with white (the French *gouache*). There are women artists who excel in water-color work of each kind.

WATER-GAS, a mixture of gases produced by the action of steam on incandescent carbon. The carbon first decomposes the steam, forming hydrogen and carbon dioxide, and the latter gas then combines with more carbon to form the inflammable carbon monoxide. Thus water-gas may be considered economically a mixture of hydrogen and carbon monoxide with certain impurities. Its especial value as a fuel lies in the fact that 90 per cent of its volume is combustible, while the ordinary producer-gas is but 30 per cent combustion. Pure water-gas is non-luminous, but it is rendered luminous by mixing with it various gases obtained from petroleum, the luminous mixture being known as carbureted water-gas. Two chief methods are employed for the manufacture of water-gas for illuminating purposes. In the first of these, the Lowe process, the preparation of the pure gas and the carbureting are performed in one operation. The apparatus consists essentially of a generator, filled with anthracite or coke, in which the non-carbureted gas is produced; a carbureter, a circular chamber lined with fire-brick and filled with a checkerwork of the same material; and a superheater, a taller circular chamber similarly filled. By means of air-blasts and the producer-gas from the anthracite of the generator, the fire-bricks of the carbureter and the superheater are raised to a red heat, and then superheated steam is passed through the incandescent carbon. The product at this stage is known as «blue water-gas» and burns with a very hot, non-luminous flame. It is useful for many manufacturing purposes. To make it available for illuminating the water-gas formed is carried over into the carbureter, where it becomes mixed with the highly carbureted gases formed by the action of the heated bricks on mineral oil, which is introduced from above. This process is completed in the superheater, and the carbureted gas is then ready for purification process in which the

sulphureted hydrogen and carbon dioxide components are removed. In the Wilkinson process the operations of making the gas and carbureting are separate. In the United States carbureted water-gas has largely replaced coal-gas as an illuminant, partly because of its brighter light and partly because it can be more cheaply manufactured. Illuminating gas made from coal is often mixed with carbureted water-gas in order to increase its illuminating power. The chief objection to the use of water-gas as an illuminant is the highly poisonous nature of one of its largest constituents, carbon monoxide. By keeping the percentage of this constituent down to 16 per cent of the total volume, the mixture is not more dangerous to inhale than ordinary coal-gas. See GAS, NATURAL.

WATER GLASS, a substance which, when solid, resembles glass, but is slowly soluble in boiling water, although it remains unaffected by ordinary atmospheric changes. It consists of soluble silicates of potash or soda, or a mixture of both. The soda glass has the formula, $Na_2O.3SiO_2$. A substance of this kind was first discovered, so far as is known, by Van Helmont in 1640. In the 19th century Dr. Johann Fuchs of Munich did much to improve the mode of preparing and applying it. Water glass may be prepared in two ways, called wet and dry. The former method is used where the proportion of alkali may be so large as 50 per cent, in which case the sand and alkali may be simply boiled together. Where a water glass richer in silica is required the mode of preparation consists in breaking down and calcining flint nodules, the fragments or particles of which are then added to a solution of caustic potash or soda, whereupon the whole is exposed for a time to intense heat at 60 pounds pressure. Sand may be used instead of the flint. According to the product when prepared in this way is viscid, and may be used in this state or further diluted. In this method of manufacture the caustic soda or potash may be replaced by the carbonate or the sulphate. Potash water glass is more soluble than soda water glass, and if both metals be present a still more soluble glass, called double soluble glass, is obtained. Among the purposes to which water glass is applied are painting on glass, coating stone, wood and other materials to render them waterproof or fireproof, glazing scenery and paintings, etc. It is also used mixed with sand to make an artificial stone, and it forms an ingredient indispensable in the manufacture of fireproof cements, such as are used in joining firebricks in furnace construction. For this purpose it is commonly mixed with lime. One of the most valuable of its applications is in the fixing of wall-paintings, by spraying with the water glass. They are thus rendered more durable than in the ordinary process of fresco-painting.

WATER HAMMER, the name applied in the laboratory to a vessel partly filled with water, exhausted of air and hermetically sealed. When reversed or shaken, the water being unimpeded by air, strikes the sides with a sound like that of a metal striking against glass. In hydraulics the term is used to designate the sudden rise of pressure in a pipeline due to the check of flow of the liquid running in it — as by the sudden closing of a valve. The strain on the pipe and any motor connected openly with it is often very serious. The formulas which are used to calculate this strain are $\frac{pr}{t}$ = the circumferential stress in the pipe walls; and $\frac{pr}{2t}$ the longitudinal stress — where p represents the increase in pressure in pounds per square foot; r the radius of the pipe in feet; and t the thickness of the pipe in feet. The hydraulic ram (q.v.) operates by water hammer. The technics of water hammer is exhaustively discussed in Gibson, A. H., 'Water Hammer in Hydraulic Pipe Lines' (Manchester, England, 1908).

WATER-HEMLOCK, deadly poisonous plants (*Cicuta*) of the carrot family, known also by many other names, such as beaver-poison, spotted parsley, muskrat-weed and musquash-root, the latter names being borrowed from the muskrat, which inhabits such swamps as the *Cicuta* affects; and the odor of the roots of certain species of the latter also recalls the musk-scented rodent. *Cicuta maculata* is a tall biennial, reaching eight feet in height, with a rigid, hollow stem marked with purple lines, that grows in swamps and wet lands throughout the northeastern United States. The leaves are decompound, even three-pinnate, having coarsely serrate leaflets, with veins apparently ending in notches instead of at the points of the teeth, as in ordinary foliage. The flowers are very tiny and white, in decompound, terminal umbels, with unequal pedicels. The fruits are ovate-oblong, glabrous and slightly flattened laterally. The ribs are corky, the lateral ones being strongest. Spindle-shaped, tuberous roots cluster about the base of the stem, and are the cause of many deaths. They have an aromatic flavor and fleshy substance, and are frequently mistaken, especially by children, for the roots of sweet cicely, parsnips, artichokes, or even horse-radish, and are sometimes eaten for no particular reason except that they are fleshy and exposed by washouts, freezing or digging-operations. Even livestock are killed, not only by feeding on the tubers themselves but by drinking water poisoned by roots which have been crushed under the cattle's hoofs. The poisonous element in this *Cicuta* is an aromatic oily fluid, which permeates the whole plant, but is found chiefly in the roots, and probably contains the alkaloid conine and the bitter principle cicutoxin. When eaten *Cicuta* produces vomiting, colic, staggering and unconsciousness, and finally frightful convulsions which end in death. No chemical antidote being known, the only treatment possible is to cleanse thoroughly the digestive system, and treat each stage of the attack with such medicines as seem necessary. Cattle may sometimes be saved by timely and repeated doses of melted lard. The elongated spindling-roots of the Wyoming water-hemlock, *Cicuta occidentalis,* which in Montana is known as the wild parsnip, has a characteristic musky odor, and stock are poisoned either by the young plants or by the roots. Other species of *Cicuta* have a similar appearance above ground and are equally poisonous.

WATER-HEN, or **MOOR-HEN,** a rail (*Gallinula chloropus*), generally distributed throughout Europe, Asia and Africa. Its length is about 13 inches; back, wings, rump and tail rich dark olive-brown; head, neck, breast and sides dark slate gray; thighs and flanks streaked with white, belly and vent grayish white; beak yellowish, becoming red; naked patch on forehead red; legs and toes greenish-yellow, claws dark-brown. The female is rather larger and more vividly colored than the male. They frequent ponds covered with aquatic herbage, overgrown water-courses and the banks of slow rivers, swimming and diving with facility, assisted by an expansion of the membrane along the sides of the toes. The water-hen is representative of the sub-family *Gallinulinæ* of the rail family (*Rallidæ*) which comprises 30 or 40 species found in all parts of the world. In the United States they are generally known as gallinules or mud-hens, and are represented by the purple gallinule (*Ionornis martinica*) and the Florida, or common gallinule (*Gallinula galeata*). The American coot (*Fulica americana*) is also frequently called a water-hen.

WATER-HICKORY. See HICKORY.

WATER INCH, *in hydraulics,* a measure of water equal to the quantity discharged in the 24 hours through a circular opening of one inch diameter leading from a reservoir under the least pressure, that is, when the water is only so high as to cover the orifice. This quantity is about 500 cubic feet. In irrigation, the term is used synonymously with "miner's inch," which is the volume of water which flows in one hour through an aperture one inch square, the sides being horizontal and vertical, under a head of six inches measured from the upper edge of the aperture. The flow amounts to 673.2 gallons per hour.

WATER LAWS, the body of legislative enactment and legal decisions governing the rights to the use of water. In comparison with the laws concerning ownership of land and of other property the water laws, particularly in the United States, are extremely complicated. There is a great amount of law with apparent lack of consistency in the prevailing legislation and decisions. The cause of this lies largely in the physical fact that water as a substance varies in quantity from day to day and until recent years the principles governing its occurrence and the methods of measurements have not been well understood. In fact they are still more or less of a mystery to many members of law-making bodies. More than this there has been an attempt to apply rules of law which while suitable for permanent or fixed objects are hardly applicable to a substance the component particles of which are ever flowing away and are ever renewed, but in fluctuating quantity. To illustrate some of the different conditions and viewpoints take first the case of a natural spring or pond on a certain tract of land. It is generally conceded that ownership of the land carries with it the full right to the use of this small body of water. If, however, the spring or pond discharges onto a piece of land belonging to another proprietor, it is obvious that the second owner has certain rights due to the fact that the stream flows along or across his land. Under ordinary conditions the upper owner may not deprive the lower of his fair share of the water, at least for drinking purposes for man and beast. The stream flows on continually, joins with others and becomes a boundary line between proprietors Each through his ownership of the land claims certain riparian rights in the flowing water. The stream finally becomes of such size as to be of importance to the whole community or State and the latter sometimes claims proprietorship in the bed and banks, these being held by the State for the benefit of the public. It finally becomes of navigable capacity, and, under the terms of the prevailing interpretation of the Constitution of the United States regarding commerce, the control is vested in Congress. In the older part of the country where, under humid conditions, there is usually ample water and to spare, the rule is that each riparian proprietor shall permit the stream to flow through or along his land undisturbed in quantity and unchanged or unpolluted as to quality — his rights being bounded by those of all his neighbors above and below, each having a fair share in the use of the water provided he does not interfere with rights of others. He may utilize the water for power if in so doing he does not overflow the lands of others nor interfere with established usages nor with the enjoyment of similar opportunities by others. If, however, a municipality finds it necessary to take water from a stream, it must be prepared to make compensation for any possible rights which may be interfered with. As a rule it cannot exercise the right of eminent domain outside of the borders of the State in which the city is located. It may be thus narrowly circumscribed and hindered from its best growth because of artificial restrictions imposed by State lines.

In the arid and semi-arid regions in the western part of the United States the common law of England, which has been followed in the humid East, is not in accord with the common necessities of the people. There it is possible to cultivate the ground successfully only through the artificial application of water. The lands will remain unproductive and population cannot increase unless the waters are taken from their natural channels to be spread over the ground and the stream channels left practically dry. The rights of riparian proprietors can be no longer observed, as in Eastern States, where under ordinary circumstances there is enough water for all. Out of the necessity of the people has thus grown an entirely different theory, namely, that of appropriation — this being limited to beneficial use, each appropriator being permitted to take usually only so much water as is needed for the irrigation of his land; even in this he may be required to show an economic use. In the case of two or more appropriators not finding enough water to satisfy their needs, the rule is usually enforced to the effect that first in time is first in right, although this rule is being modified in practice in accordance with larger equity, for example, if the first in time is at a place where there results great waste in getting

the water to him, consideration may be taken of the fact that to irrigate one acre thus situated many acres better located must be left dry.

The common law of riparian rights such as prevails in the eastern or humid part of the United States, but modified to a considerable extent, is recognized in California, Kansas, Montana and Washington. The civil-law doctrine declaring that the waters are the property of the state is contained in the constitution of Wyoming; similar declarations are made in the laws of Idaho, Nevada and Texas. By the constitution of Colorado the water of every natural stream is declared to be the property of the public and dedicated to the use of the people of the state. Similar declarations are contained in the water laws of Nebraska, New Mexico, North Dakota, Oklahoma, South Dakota and Utah. Under the so-called Wyoming system the water rights are in theory acquired by grant from the state. There is great difference among the Western states with reference to the control of appropriation. In some states this control is vested in a state board with right of appeal, however, to the courts. In others adjudication proceedings are initiated in the courts. Because of the difficulty of ascertaining the ordinary supply of water and because of the exaggerated claims which are made to its use there have arisen innumerable controversies so that in some parts of the arid region more money is being expended in litigation than in actual irrigation. In most states in which water rights are adjudicated by courts, the law provides that all parties claiming rights to water from the same source shall be made parties to the action so that all rights may be determined in a single action. Without such provision, there may be an interminable succession of suits, A bringing B into court to determine their respective rights, then C coming in and upsetting the arrangements and so on through the entire alphabet. The interest of the public or of the state is not necessarily taken into consideration at any time.

There are conflicting theories which arise from a difference of opinion as to the origin of rights to water Throughout a greater part of the East there is insistence upon the conception that all rights to the use of water abide in and are derived from private or personal proprietorship of land and that any attempt at the invasion of the sanctity of property will result disastrously. Nevertheless attempts have been made and are continually being made to preserve the rights of the public and by asserting the theory of state ownership and control of water, to set a limit to the broad claims of riparian owners. Further than this there is still a third class who claim that the federal government has the right and duty on behalf of all the people and for the general welfare to extend its authority beyond the narrow limitations of preventing interference with navigation, and to legislate in such a way as to prevent this great natural resource from being exploited wholly for private gain, especially as to those waters which have not already been appropriated or put to beneficial use. There is continual attempt of riparian owners and of large moneyed interests to extend and strengthen their control of water rights. At the same time efforts are being made by the state legislatures and by the federal Congress to enact legislation protecting the general public in the proper enjoyment of water, which, like air, is essential to all life whether human, animal or vegetable. The conflict between these opposing theories and views is resulting in innumerable statutes and court decisions, many of them apparently irreconcilable. The unfortunate feature is that, besides provoking litigation, the largest and best uses of the waters of the country are not being given full consideration.

F. H. Newell.

WATER LEMON. See Passion Flower.

WATER LETTUCE, a fresh water herb (*Pistia stratiotes*) of the Arum family, indigenous to tropical and subtropical regions. It is a perennial, with long cordate leaves, and feathery roots. It bears pea-green velvety rosettes of wedge-shaped leaves about six inches in length and resembling the lettuce plant which gives it its name. In the cup-like rosettes are centered small white blossoms. In the United States it grows from Florida to Texas. It is often cultivated in aquariums.

WATER LILY, a plant of the aquatic family Nymphaeaceae, and of the genus *Nymphaea.* These are found in fresh, still waters throughout the warm and temperate regions, and are often cultivated. Some can be raised easily from seed, and those which are hardy in the North will stand a very low temperature without damage, even to be encased in ice. They may be grown in tanks, or even in half-barrels, as well as in ponds. The tropical species must be raised nearly to blooming size in a greenhouse before being planted outside. The water lilies are handsome plants, having more or less orbicular leaves, either floating, or more rarely emersed, and solitary flowers, of similar varying habit. The blossoms have four sepals and many petals, stamens, and carpels, the latter united and immersed in a thickened receptacle; in color they may be white, pink, yellow or blue, and are sometimes very fragrant. The flowers of some species open by day and close at night; others open at night and close by day. The duration of one flower is usually three days. If pollinated the flower is drawn to the bottom of the pond or tank by a bending or spiral coiling of the stalk.

The fruit is indehiscent, somewhat fleshy, and like a large berry filled with seeds. The seeds have small embryos and abundant starchy perisperm, and are enclosed in pulpy arils. When the seeds are ripe the pod breaks open irregularly. The seeds are borne to the surface of the water by the buoyant arils, where they repel each other and float far and wide by changes in surface tension and by currents of water and wind. After one or two hours the aril contracts, breaks loose, and lets the seed drop to the bottom of the pond. Nearly all of the known 40 species have been brought into cultivation, and countless hybrids have been produced, both in the hardy and tropical groups. One of the finest is the Australian water lily (*Nymphaea gigantea*). Its flowers are sometimes a foot across, with hundreds of stamens, and the color is blue, pink, or white. It does not close so completely at night as do other water lilies. The Egyptian lotus (*Nymphaea caerulea*) that was a favorite plant of the ancient Egyptians is often confounded with the Indian lotus (*Nelumbo,* q.v.), but is really a blue flowered water lily, with flowers borne on stiff stalks a foot above the water. It was a valuable plant to the decorators of that country,

WATER LILY

Tropical water lilies (*Nymphaea*) shown above, *left to right*, bear the popular names Blue Beauty and Mrs. C. W. Ward.

Top: Nymphaea (Castalia) americana. Bottom: Nymphaea (Castalia) capensis.

who copied it, and conventionalized its form in many of their architectural ornaments, and also introduced it constantly into their painted pictures of life and customs. Its rootstock and seeds served as food. (See LOTUS.) The European water lily (*Nymphaea alba*) has white flowers that usually float upon the surface of the water. The flowers are not fragrant, as are those of the American water lily (*Nymphaea odorata*). The latter lovely water lily rides upon the water, with snow-white petals radiating in circles, the inner gradually narrowing, and passing by various stages into golden stamens in the center. They open in sunshine about 6 A.M., and close in the early afternoon. The fruit is ovate and baccate and ripens under water. The leaves, or lily pads, a favorite food of deer, are ovate-orbicular, with a deep sinus, and have very long cylindrical stems of unvarying thickness, great flexibility, and toughness. The thick, fleshy creeping rootstock furnished a brown dye for the early settlers, and was also used as a styptic, and tonic. A variety of this water lily is smaller and has rose-colored flowers. There are four other species of *Nymphaea* in the United States, including the handsome golden-flowered water lily (*Nymphaea mexicana*) of Florida and Mexico. See also LOTUS; NYMPHAEACEAE; VICTORIA.

HENRY S. CONARD.

WATER LINE, (1) a nautical term which describes any of several lines marked upon a vessel, corresponding with the surface of the water when the vessel is afloat on an even keel. The lowest line indicates the vessel's proper submergence when not loaded; the highest line the vessel's proper submergence when loaded.

(2) The term is used in shipbuilding to designate on the model or plan the surface of the water at various heights from the keel.

(3) A line produced as a watermark on paper.

(4) The level represented by the uppermost limit of ground saturated with water; a water table.

(5) A line of stain marking the junction of a former leaning roof.

(6) A shore line.

(7) The desired or actual level of water in a tank or boiler.

WATER LOCUST or **SWAMP LOCUST,** of the genus *Gleditsia aquatica,* and family Leguminosae. It is a variety of the honey locust indigenous to the Southern states. It is found from Kentucky to the Gulf of Mexico, and from South Carolina to Florida. It is a beautiful tall tree, with enormous spines, and reddish oval pods. Its dark, heavy wood takes a very high polish. See also LOCUST.

WATER MARK, (1) The mark or limit of the rise of a flood or the mark indicating the rise and fall of the tide. (2) In paper-making, any distinguishing device or devices appearing in translucent lines in the substance of a sheet of paper. It is produced by a pattern of wire built upon the web and receiving heavy pressure from the rolls as the film of pulp passes through them while yet in a damp or pulpy condition. The water marks used by the earlier paper-makers have given names to several of the present standard sizes of paper, as foolscap, crown, elephant.

Although the Chinese are credited with the invention of paper, the Italian papermakers of the late 13th century were the first to use water marks. These were usually simple geometrical designs that could be twisted easily in wire. Animals were also favorite water marks of the early papermakers. In 1818 Sir William Congreve (q.v.) invented water marking in color and obtained a patent for it in December 1819.

WATER METER, a mechanism by which the quantity of water or any other liquid flowing through pipes is measured and recorded automatically. They are of three general types—the "positive," the "inferential" and the "proportional" meters.

Positive meters measure the actual volume of the water, by the action of a piston working in a cylinder which is successively emptied and filled at the completion of each stroke. The cylinder being of known dimensions affords a measure of the quantity of water introduced. The pistons are either reciprocating or rotary, or of the oscillating or gyrating disc patterns and they may be single or double. When single, a weight or spring produces the return stroke, but in the case of the double arrangement, the reciprocal action of the two pistons is controlled by the action of each other, as in the case of a duplex pump. In rotary piston meters, which may also be of the single or double type, the pistons have interlocking faces and rotate in an airtight chamber. Upon the outer surfaces of the pistons are a series of projections and recesses which correspond to similar shapes on the inner walls of the cylinder. The pressure of the flowing water causes the piston to turn so that a series of recesses or chambers in the cylinder are successively filled and discharged from the inlet to the outlet of the meter. When oscillating or gyrating discs are employed in the place of pistons, the wabbling motion of the discs alternately empties and fills the cylinder. Inferential meters measure the velocity of the flowing water by recording the revolutions of a turbine or other water-wheel attachment, and the quantity is deduced by computation from that record. Proportional meters measure a fractional part of the full flow and are, therefore, capable of being set on a small by-pass pipe which branches from and subsequently rejoins the main pipe, but being only approximately accurate their use is limited.

The registering mechanisms consist of a series of gear wheels and dials. The flow of the water actuates the gear wheels, and the number of revolutions are recorded on the dials. The arrangement of the mechanism converts the number of revolutions into any desired unit of volume, so that the reading of the dials is termed straight and gives the quantity direct, in cubic feet, the unit generally adopted, particularly in the United States.

The working parts of meters are made light and durable. Serviceability and accuracy are the qualities required, and in their design the support of the water pressure is employed to reduce to a minimum the loss of head, and the wear and tear of the working parts, and although a high degree of accuracy is not generally required, the meters are made sufficiently sensitive to measure the small flows incident to leakage. Hard rubber is generally used for the discs, and also for the rotary pistons of some meters, but where the liquids are hot, or consist of chemical solutions, brass is generally

employed. Possible damage due to clogging by the introduction of fish or gravel is prevented by various forms of strainers and sieves, while effect of frost is guarded against by frost cases.

There are several forms of meters which do not come under the general classes already described. Of these the "Venturi," constructed by Clemens Herschel of New York, in 1886, is the superior and most useful on account of its simplicity and durability. Its basic principles — the relation between the reduction of pressure and the increase of velocity of water flowing through a contracted pipe, was discovered by Venturi in 1796. In construction it consists of two conical shaped pipes with their smaller ends joined together by a collar or throat-piece, resulting in a shape similar to a pipe contracted at one point of its length. By gauging the pressure of the water at a point just before, and also directly at the point of contraction, and the relation of these pressures to the diameter of the pipe, the volume of the flow is computed. The tubes are usually constructed of cast iron or riveted steel, but they may also be constructed of masonry or wood. The length of the meter varies from 8 to 16 times the diameter of the uncontracted portion, while the diameter of the contraction ranges from one-fourth to one-half of the full diameter of the tube. They are made in sizes varying from two to about 100 inches, with practically no limit to the possible maximum size, but for practical use where meters of diameters less than six inches are required those with moving parts are cheaper. Waste-water meters are employed in connection with waterworks to measure the rate of consumption per unit of time, instead of the total volume. They consist usually of a disc placed horizontally in a cone-shaped chamber. The disc is lifted or lowered according to the greater or lesser volume of water passing through the pipe in which it is set, and being connected by a wire with counterweight and pencil which follow the movements of the disc, records the nature and amount of those movements on a paper carried by a drum which is revolved by clockwork. The vertical rulings of the record sheet indicate the time intervals, while the horizontal lines represents the units of volume. Since all the water consumed in a given district must pass through such a meter, by comparing the rates of consumption of the various districts, the causes of abnormal waste are readily determined and localized.

Another form of water meters, more particularly known as current meters, are employed in hydraulic engineering to measure the velocity and volume of flow of the waters in rivers, large aqueducts and sewers. See CURRENT METER.

WATER-MOCCASIN, a snake. See MOCCASIN.

WATER-MOLDS. See FUNGI.

WATER MOTOR. In its broadest sense the term is applicable to all forms of machines or systems of machinery operated by water under the force of gravity, or in other words, by which the energy inherent in a natural waterfall is utilized to perform mechanical work. There are three types of such motors, classified as (1) gravity motors; (2) pressure motors, and (3) impulse motors. Of these machines, the water-wheel (q.v.), the turbine (q.v.) and the pump (q.v.) have been treated under their respective titles, but in this article the term will be considered as designating those machines which are operated by the element of pressure only, such as hydraulic lifts and water pressure engines.

The Hydraulic Lift, used in elevator service, is the simplest of all water motors. The direct-acting lift consists of a cylinder in which a ram or piston of equal length, with a cage attached to its upper end, works up and down. The level of the water supply must be necessarily above that of the maximum height through which the cage may be lifted, so that when the water is admitted to the cylinder at its lower end, the pressure forces the ram upward and thus lifts the cage. The descent of the ram is accomplished by closing the supply valve and opening the discharge valve, the ram descending by its own weight. As the weight of the ram is greater than necessary to bring down the cage, a part of that weight is balanced by a counterweight attached to the end of a chain that works over a pulley at the top of the lift and is connected to the cage. The most familiar examples are the high-speed hydraulic passenger elevators. They are operated by the pressure of water pumped into tanks situated on the roofs of the buildings in which they are installed, while the operating machinery is located in the basement. (See ELEVATORS). The hydraulic press and the hydraulic ram are devices operated practically under similar principles. In the former, the action depends upon the principle of hydrostatics that a pressure applied to any part of the surface of a liquid is transmitted in all directions and throughout the mass without diminution. For example, if a cylinder filled with water has a plunger one inch square working through one end and another 10 inches square working through the other end, and a pressure of one pound is exerted on the smaller plunger, this pressure will be transmitted to the larger plunger and be delivered by the latter in a multiplied amount equal to the square of its face area expressed in pounds. In this example that pressure would be 100 pounds. Such presses consist essentially of two cylinders connected by piping. The pressure is applied to the plunger of the smaller cylinder and the multiplied pressure is transmitted by that of the larger to the object to be raised or pressed. In construction they vary greatly with the purpose for which they are employed. Those used as hay, cotton and oil presses consist of four strong iron pillars arranged in the form of a square, which carry a cast-iron plate solidly attached to their tops. A similar casting is situated at the bottom of the pillars. Through a circular hole in the centre of the lower plate, a plunger carrying a square platen on its head works with an upward motion and presses the material placed between the platen and the under face of the top plate. In presses used for hydraulic forging, the cylinder and plunger are carried by the top plate, while the bottom plate carries the anvil. The plungers work downward in the act of pressing or hammering. They are made of various sizes and are generally provided with two pressure plungers and cylinders and they are adapted for purposes varying from the manufacture of revolver cartridge cases to the

forging of armor plate, guns and steamship shafts. Armor plate presses capable of exerting a pressure of 14,000 tons are in use, while 7,000-ton fluid compressors are employed in many of the larger steel manufacturing plants. A brief description of the construction and working of one of the last-named capacity will serve to illustrate the mammoth proportions and enormous power of these machines. It consists of an upper head weighing 120 tons carrying the plunger and a 135-ton base plate containing the hydraulic cylinder. These are supported and held in place by four vertical connecting columns each 50 feet long, and 19 inches in diameter. In operation, the molten metal is poured into a mold built up in sections and the mold is raised under a hydraulic pressure of 7,000 tons, while a plunger attached to the upper head bears down upon the fluid metal and compresses it.

Hydraulic Ram.— In the hydraulic ram the force of water flowing by gravity is utilized to raise a portion of its volume to a height above that of the source of supply. Two pipes are employed. The water in flowing through the main or drive pipe acquires sufficient momentum to close a valve at the foot of the pipe, and the water thus confined automatically opens another valve, partially fills an air chamber situated over the foot of the main pipe and compresses the air in it until the pressure within balances the column of water in the main pipe. Then the foot valve of the main pipe opens again and the action described is repeated. In the meantime, the pressure in the air chamber forces the water through a small service pipe leading out of its bottom, to the required height. See HYDROSTATIC PRESS; HYDRAULIC RAM; POWER TRANSMISSION; PUMPS AND PUMPING MACHINERY.

Hydraulic Engines.— In the hydraulic lifts or elevators, the admission and discharge valves are worked by hand at the will of the operator, but in the engines the mechanism actuates the valves automatically and periodically, thus converting the lift into a machine with a continuous action. Unlike the vertical water wheels and turbines, the efficiency of which depends upon the weight of a large body of water falling from a comparatively small height, the water engines work under the pressure of a small column of water descending from a considerable elevation. They are of three types — the "single action," in which a piston working in a cylinder is moved upward by the pressure of the water, and downward by the weight of the piston itself; the "double action," in which the cylinder is closed at the top as well as at the bottom, and the water admitted to it by supply pipes at those points, acts reciprocally on the piston from above and below; and the "rotary," in which the water pressure acts on a revolving piston similar to that of a rotary steam-engine. Rotary engines may be of the single-acting or double-acting type, the advantage being with the former, since the pressure of the piston is always exerted on the crank pin in one direction and the dead centres are passed without knocking. Generally three single-acting cylinders formed in one casting are used in connection with a disc valve with segmental posts which pass over corresponding apertures in the valve seating, during rotation and the engine will readily start in all positions. The first engine of this kind was constructed by Sir William Armstrong, who also subsequently designed one of the reciprocating pattern. Since then a great variety of hydraulic engines have been invented, the greater number of them being of the last-named type. (See HYDRAULIC ENGINE). They have a wide field of usefulness, especially as auxiliary motors for driving small machinery such as hoists, swing-bridges, capstans, cranes, winches, etc. The employment of superheated water motors is one of the latest developments in the methods for railroad traction. In the earlier forms of engines operated by superheated water, the storage tank being charged with water at a temperature corresponding to several hundred pounds of pressure, only the steam from the water was utilized in the cylinders of the motor, in a manner similar to the utilization of steam from the boiler of a locomotive engine by expansion in its cylinders. Their operation was based upon the relation of temperature and pressure to the vaporization of liquids and the steam was drawn off from its point of formation at the top of the storage tank to the cylinders. Under these conditions, with each revolution the new steam was supplied by water which boiled at continually lower and lower pressures and reduced temperatures, until the pressure fell to a point at which it was not available for use in the motor; and only about one-ninth of the energy of the heated water was actually used in the cylinders. W. E. Prall of Washington, D. C., suggested the utilization of the power in the storage tank by withdrawing the superheated water directly from the bottom of the tank instead of steam from the top and allowing the water thus withdrawn to expand into steam within the cylinders of the engine itself. In the latest motors, this is accomplished by a generator composed of a nest of tubes coupled into manifolds at the top and bottom. The working pressure is about 700 pounds to the square inch and the water is drawn off from the generator into three insulated storage tanks with a total capacity of 7,000 pounds, carried beneath the car. From the bottom of the tanks the water is delivered through three Tappet valves provided with screw and nut adjustment to regulate the amount of feed. In operation, under the decreasing pressure caused by the movement of the piston through its stroke, the water resolves into steam in a continuous series of flashes, the steam and the unevaporated portion of the water from the high-pressure cylinders passing out through the ports in its bottom and draining off through valves in the lower face of the valve chest. The exhaust steam from the high-pressure cylinder passes in the usual way to the low-pressure cylinder and is eventually exhausted into the atmosphere. A car equipped with two compound engines and three tanks charged with water at a pressure of 700 pounds to the square inch and a corresponding temperature of 500° is capable of running 40 miles at a speed of from 30 to 40 miles an hour.

WATER PLANTAIN, an aquatic or marsh herb of the genus *Alisma,* family Alismaceae, of which *Sagittaria* is also a member. The plant most commonly known as water plantain is that found also in Europe and Asia (*Alisma plantago aquatica*), which grows in mud or shallow water. It has a circle of radical long-petioled leaves, ribbed ovate and strongly resembling those of the common plantain. The scape, which is usually solitary, branches verticillately, and forms a large, open pyramidal, flowing panicle; the blossoms are very small, white or rose-colored and have their parts in threes.

WATER POLO, a game played by opposing teams of swimmers in both indoor and outdoor pools. Invented in England in the 1870's, it became popular in other countries a decade or more later. In the early 1900's "American Water Polo," a soft-ball variety, was popular; but it was soon superseded by the faster, more scientific European hard-ball game, played in Olympic contests.

WATER POWER. Water power is one of the important sources of energy required for operation of the ever increasing machines and equipment of modern civilization. The most extensively used sources of energy are the fuels produced through the action of sunlight millions of years ago. These fuels, coal, oil, and natural gas, are practically irreplaceable and on the basis of estimates the latter fuels will be exhausted in about 300 years with the coal supply limited to less than 3,000 years. Other sources of energy will become increasingly important with time. Such power sources include atomic, solar, tidal, wind, and water. At the present time, water power is extensively used on a large-scale commercial basis, atomic power gives great promise but much development work remains to be done before it can compete successfully as a power source, and the others have been demonstrated to work but they are not of practical importance in the industrial sense. Solar energy is important as combined with plants and soils it is capable of supplying energy in the forms of food, wood, and alcohols. In this sense it is a perpetual source of energy similar to water, but when considering the total amount of power required, the output from this source for industrial purposes is much less important. In the United States, about one third of the power produced by the public utility power plants is from water, the remaining two thirds being from fuels. In the state of California, where high mountains and reasonable rainfall exist, water power accounts for about two thirds of the total power used. The ratio of water to fuel power varies widely from country to country depending upon the availability of hydrocarbon fuels and water power sources.

In a water power system, water in one form or another is the working substance. Evaporation takes place from water surfaces exposed to sunlight and winds. Since a majority of the earth's surface is covered with water, the magnitude of the quantity evaporated is enormous. The evaporation process removes water from the source and adds to the water vapor content in the air over the source. By this process the relative humidity of the air is increased. At the same time, industrial applications of the loss in water from the source serves as the process for producing salt from sea water, dehydrating fruits, etc. Under average conditions prevailing in the United States, more than 0.1 inches of water are evaporated each day from the water surface of a fresh water lake. Due to density currents, the air and water vapor at a low elevation will be moved, both horizontally and vertically to a new location on the earth's surface. Under appropriate conditions, instability may occur and the water vapor become separated from the air in the form of rain, snow, or ice. Water in these forms is heavier than the surrounding air, thus under the action of gravity, the rain, snow, or ice falls to the earth. When these phenomena take place in the high mountains, water collects on the earth's surface at a high elevation. Under natural processes this water will flow to the ocean through a network of rivers, using up its potential energy in soil erosion and the production of heat through turbulence and viscous action. Through construction of proper works and machines, a portion of this wasted potential energy may be made available for the use of man. In any event, the water flows to an area where it is evaporated and the process repeated. If all rain and snow falling on the surface of the earth were made to pass through suitable machines for converting all of the potential energy of the water above sea level to mechanical work, it has been estimated that this would provide enough power to maintain our present energy requirements indefinitely. Such a system is impractical. On the basis of present economics, about a tenfold increase in water power throughout the world appears to be the optimun to be expected, the greatest contributions coming from the countries that are not at present highly industrialized.

A complete water power plant consists of many elements. The prime mover for converting the energy in the water to mechanical energy is the key piece of equipment. This may be a water wheel or hydraulic turbine (see TURBINE —*Hydraulic*). In the case of a large hydroelectric plant, the prime mover shaft is connected (usually directly) to the shaft of an electric generator, the electrical output passing through transformers and high voltage transmission lines to the location for application of electrical energy. In some cases, particularly smaller plants, the shaft of the prime mover is connected directly to mechanical equipment requiring the energy for operation. Normally, the prime mover must operate at constant speed of rotation under variable hydraulic head and output load. Auxiliary control equipment such as speed governors, wicket gates, and control valves, are essential parts of the prime mover. Since river flow is variable as well as the load demands on the water power plant, some type of water storage system becomes necessary for dependable and efficient plant operation. This involves storage reservoirs usually formed by some type of dam with flumes or penstocks to convey the water to the prime mover and associated installations as trash racks, ice protection equipment, surge chambers, and draft tubes.

The first hydroelectric central station in the United States was installed at Appleton, Wis., in 1882. The use of hydroelectric power for lighting advanced rapidly during the 80's, this advance following quickly the invention of the

incandescent lamp by Thomas A. Edison in 1879. While there were some previous experiments carried out, the first large-scale successful long distance power transmission was that from Lauffen to Frankfort, completed in 1891, by which 110 horsepower was transmitted a distance of 112 miles at 12,000 volts. This provided the initial stimulus for extensive hydroelectric power development. Prior to that date, water power was not much used for the generation of electric current unless the water power happened to be located very near the site where the current was to be used.

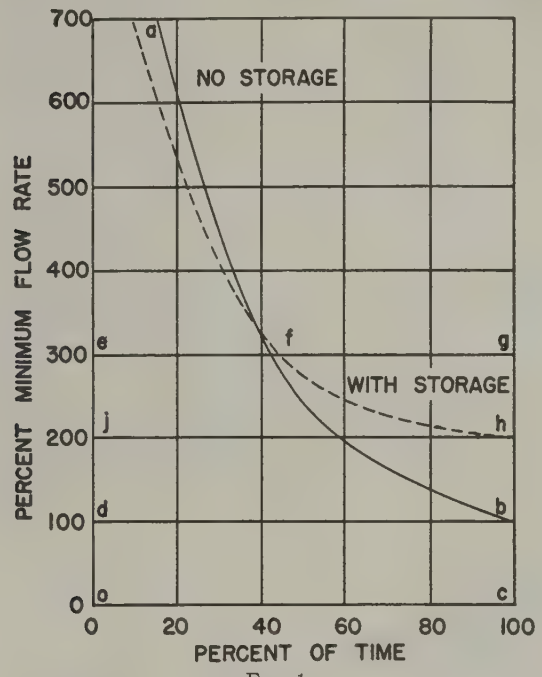

FIG. 1.

The growth of hydroelectric power development has taken place mainly along natural economic lines. The general water powers near large industrial centers were developed first, and of these, those involving the lowest primary investment have been given preference; furthermore, the first water power developed in a locality has generally been that having the size suited to the demands of the immediate future. Thus it happens that some of the very largest water powers, as well as numerous smaller ones, have thus far remained undeveloped. The necessity of developing powers of a size suited to the existing market conditions at the time of development is emphasized by the fact that many of the larger hydroelectric developments in the eastern United States passed through bankruptcy, but are now operating successfully. The cause of the financial difficulties was in general that it took too much time to build up an adequate market for the output of a power larger than the immediate demand, and during this time the revenue was insufficient to meet interest payments and other fixed charges on the large investment.

When the water power plant is small, its operation does not interfere appreciably with other water users due to the small water drainage area involved and the corresponding small changes in river hydraulic characteristics at any given location. With the advent of efficient electrical machinery and electrical transmission lines near the turn of the century, the size of individual water power plants increased rapidly. This growth introduced three problems, the amount of firm (primary) or continuous power that could be developed at a given installation, how to operate the plant to develop and use the maximum surplus (secondary) power, and what considerations must be made for other water users. It is seldom that a large water power plant installation is a single purpose project, generally the rights of one or more other water users are involved, that is for irrigation, flood control, navigation, water supply, recreation or wild life. Utility companies, both private and public, have solved the firm and surplus power problems by interconnected electrical distribution systems with proper proportion of installed capacity of hydroelectric plants and fuel-electric (coal, gas, and oil fired steam plants). For an isolated plant, a storage reservoir may be used to accumulate surplus water during periods of small plant output in order to provide an adequate water supply when required to meet peak loads. In some of the more modern water power plant systems, the financial requirements and the legal complexities have been such that large power development programs have been constructed and operated by the federal government. A few examples are the Tennessee Valley Authority, Hoover Dam and powerhouse on the Colorado river, Grand Coulee Dam and powerhouse, and California Central Valley project. The complexities of the Colorado River power and water usage problems are indicated by the number of states, municipalities, industrial companies, irrigation districts and even a foreign country that have important interests. Large European water power developments face similar complications due to the relatively small area included in each country.

The application of the principle of the conservation of energy demonstrates that mechanical work may be accomplished by water when the pressure, elevation of the free surface, or a change in the average velocity takes place in a suitable flow system. Several devices in common use involve one or more of these energy changes in their operation. W pounds of a liquid possess potential energy in the amount $W \times h$ foot-pounds when the center of gravity is at an elevation h feet above the reference plan from which potential energy is measured. When the water is allowed to pass through a conduit of proper proportions in flowing from a high to a low elevation, the potential energy is changed to kinetic energy and friction losses. Mechanical work may be obtained when the water flows through a suitable water motor or turbine, the magnitude of work being a maximum when the water is discharged at the lower elevation with a minimum of pressure and velocity. Neglecting all losses, the theoretical power available from a steady stream of water going from a large pool with surface elevation h feet above a similar large pool at a lower elevation may be determined from the relationship:

$$\frac{62.4 \times Q \times h}{550} = \text{horsepower (theoretical)}$$

when Q is the rate of flow in cubic feet per second. The overall efficiency of a water power plant is the power output (mechanical or electrical) divided by the theoretical power available from the water, the result generally being expressed as a per cent. Maximum overall plant efficiencies (electrical energy output to available

theoretical hydraulic energy input) of greater than 80 per cent are achieved in modern large installations.

When the load on a hydraulic turbine changes, the water flow control valve setting must be altered correspondingly or the turbine rotative speed will change. Since load changes may occur very rapidly, for example a short circuit in the transmission will trip the generator overload protection device and the whole load on the hydraulic turbine generator unit may be removed in a matter of microseconds, it may be desirable to operate the control valve rapidly. If the penstock is of appreciable length, the valve cannot be closed in a time less than about $10 \frac{L}{C}$ (L = length of penstock, feet; C = velocity of sound in water in the penstock, feet per second) without producing pressure surges. In the event the closure time is less than $2 \frac{L}{C}$, the full water hammer pressure surge is developed with a magnitude of rise about equal to 60 ΔV pounds per square inch where ΔV is the change in average velocity in feet per second in the penstock produced by the valve action. Surge chambers are installed to protect the penstock from failure. Since the water hammer waves may be reflected as negative pressure waves, pressures corresponding to vapor pressure of cold water may occur and it becomes necessary to include protection for the penstock against collapse due to internal high vacuum conditions.

made of partial rainfall records, crop records, thickness of tree rings, and similar indirect methods to estimate water flow magnitudes. Records from adjacent drainage areas are sometimes used as a basis for water flow estimates but due to geographical and meteorological phenomena, the comparison is seldom valid without large and frequently not well known correction factors. Water flow rates vary greatly throughout the year as well as from year to year. In addition to the normal variable of precipitation and snow fall, the runoff is influenced by evaporation and transpiration losses as well as ground storage and percolation. Management of a drainage area includes control of such factors as soil erosion, crops, ground cover, and storage as well as measurements of precipitation, snowfall, and runoff. A knowledge and application of modern meteorology is becoming more important. The results of these studies are expected magnitudes of minimum, maximum, and average daily flows and expected frequency of each. The minimum flow is used as the basis to determine available primary power, the maximum flow indicates flood conditions, and the daily average provides information fundamental to the design of a storage reservoir and to estimate the amount of secondary power available. These data may be presented in several ways but the most useful are the hydrograph and flow-duration curves. The hydrograph is a time history of flow rates plotted with discharge rates as ordinates and the time of occurrence in sequence as abscissas. The flow-

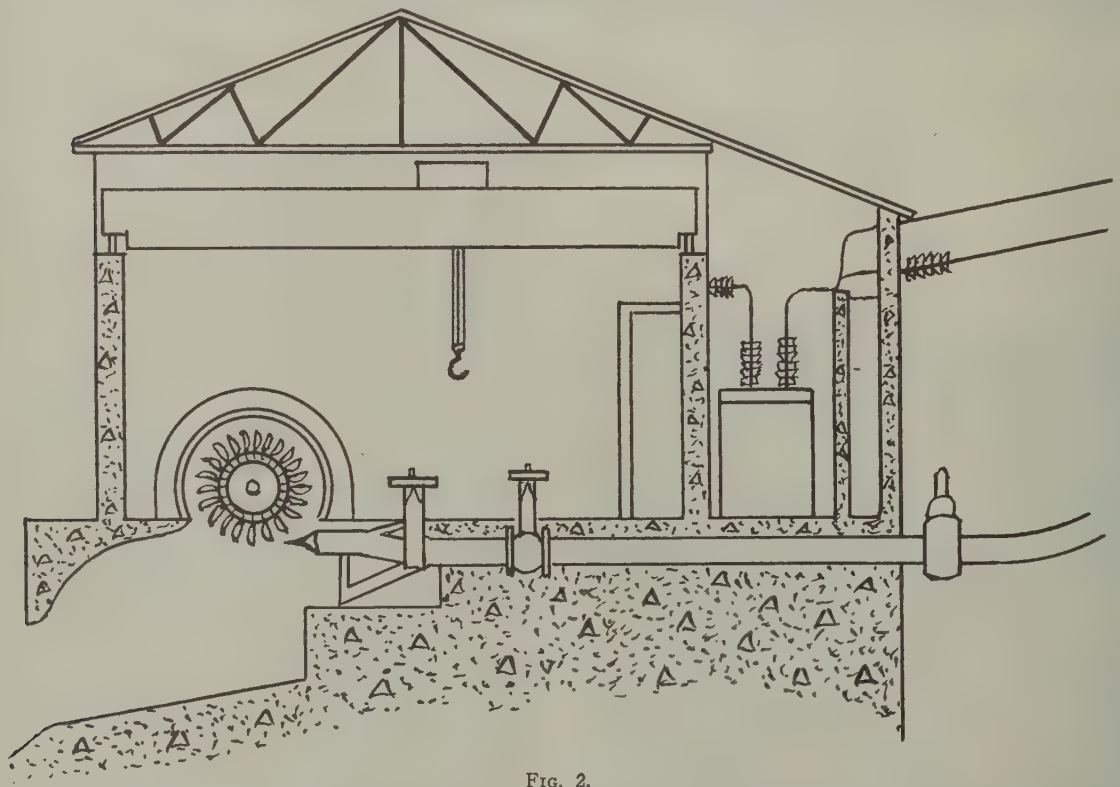

Fig. 2.

For the determination of locations for water power plants and the selection of proper size of equipment, studies are made of the available records of water flow at the proposed sites over long periods of time. Unfortunately, in all cases records of length sufficient to produce statistically significant data are not available and recourse must be had to secondary methods. Use has been

duration curves are plotted with (daily, weekly, or monthly) flow rates or any proportional factor like power (when the head available is fixed) as ordinates versus the percentage of time for a year during which the flow rate equals or exceeds the given quantity. Fig. 1 presents a dimensionless flow duration curve where the ordinates are expressed as a per cent of the minimum flow

rate which in turn establishes the amount of firm power to be expected from the unregulated flow. The area oabc on this curve represents the total amount of power available during a year. The area odbc is proportional to the annual primary or firm power. For a proposed water power plant having in installed capacity three times (300 per cent) the firm power capacity, the area defb is proportional to the annual secondary or surplus power. The power of area eaf is wasted. By construction of a storage reservoir it is possible to store some water during flood periods and release it during periods of low flow, thus increasing the primary power to the area ojhc and changing the flow duration curve at the power site to the curve in the figure marked "with storage." The economics of proposed installations can be investigated with the aid of this curve to ascertain the significance of changes in selected power capacity and reservoir capacity.

Water storage or pondage is used with water power plants in order to generate a larger portion of the available energy than would otherwise be possible. Storage volume is usually obtained through the construction of a dam in a suitable location. The dam may serve the dual purpose of creating storage and increasing the elevation of the water at the power plant and thus the energy that can be generated. Several types of materials for dams are in common usage. (Masonry or concrete, earth fill with and without cores, rock fill, wooden, and combinations.) High dams are concrete and examples constructed for reservoir and power purposes are the Hoover Dam, 726 feet in height and the Shasta Dam, 602 feet in height. Dams are of the gravity, arch and multiple arch types. The type of dam, materials for construction, and location will depend upon the foundation, earth or rock which is determined by a suitable number of cores taken from appropriate borings in the proposed foundation area, the topography and geology of the dam site, the availability of construction materials, the methods to handle the water flow during construction, methods to by-pass flood waters, and the height of the dam. The establishment of a reservoir involves factors other than design and constructional, in that land, real estate, water rights, railroad and highway rights of way and similar items must be considered. In some cases, whole towns have been moved to allow construction to proceed. Usually the area to be covered to the high water elevation is cleared of all brush, trees, etc. in order to eliminate debris that would interfere with flow into penstocks and spillways. Dams are designed to be safe against overturning, sliding, and excessive stresses. The action of surface water waves and ice frequently becomes an important problem. Head gates of different types are used to control the outlet of the normal flow and flood flows from the reservoir. Trash racks are installed upstream from such gates. An unobstructed spillway is most satisfactory for passing flood flows but often other requirements make it desirable to install various gates (Tainter gates, flashboard, etc.) with the spillway in order to control water level elevations. Special purpose structures as siphon spillways sometimes find applications. When the dam is constructed on a natural waterway, it may be necessary to provide fishways. On the west coast the salmon industry is important and dams constructed on the Columbia River include adequate fishways; Bonneville Dam has fish ladders and fish elevators.

In many water power plants the powerhouse is located at some distance from the dam and storage reservoir. This arrangement has the advantage of using additional head over that which would be available at the dam sight but is subject to the disadvantage of the requirement of a waterway to conduct water from the dam outlet to the turbines at the powerhouse. Particularly in precipitous terrain, additional power can be generated by locating the power plant downstream from the dam or even in a different watershed. The waterway is designed for low head loss and may be an open channel or canal, a closed conduit, or combinations. Canals are constructed along surface contours and are usually lined to prevent bank erosion and provide a minimum loss of head for a given cross-sectional area. Flumes or open channels carried on supports are economical for making short length crossings of valleys or ravines. Flumes are constructed from wood, metal, or concrete. Tunnels become practical when carrying water from one watershed to another, or in mountainous country where canals involve construction in rocks and are subject to ice, snow, and landslide hazards. Penstocks are pipes conveying water from the waterway to the turbines. For low pressures penstocks may be constructed from wood or reinforced concrete but the most common installations are riveted or welded steel pipe. Transition sections are necessary when the cross-sectional shape of the waterway changes. These sections require careful design to prevent undesirable flow conditions and excessive loss in head. The waterway includes protective devices as surge tanks, air valves, and air vents. Air vents are installed at the upstream end of a penstock to allow air to enter and prevent collapse of the pipe when the head gates are shut and water is drained from the penstock by opening the valve at the bottom.

When producing electrical energy for commercial use, the speed of rotation of the hydraulic turbine driving the generator must be controlled automatically within small limits to produce electric current of a constant voltage and frequency. The gates regulating the supply of water to the turbine are adjusted each time the generator load changes in order to maintain a constant rotational speed. The weight of these gates and connected parts provide a large inertia load to be overcome rapidly by the turbine governor. The principle of operation of the hydraulic turbine governor is similar to that used by other speed governors, the principal difference being in the use of a powerful servomotor or controlled auxiliary device to exert the very large forces required. The position of a pilot valve (a small valve controlling oil flow for operating a secondary valve), requiring a minimum of force to move, is determined by the difference in actual turbine speed and a constant reference standard. The secondary valves control the oil under pressure to operate the hydraulic piston actuating the turbine gates. The instantaneous relationship between the pilot valve position and the turbine gates is a function of the number and modes of control built into the governor. The governor speed input may be through direct mechanical connection to the turbine shaft, belt connection, or electrical connection with self-synchronous motor and generator. Under certain conditions, the governor action will produce excessive pressures in the turbine case or penstock unless protective equipment as pressure regulators and surge tanks are included in the installation.

The pressure regulator is a governor operated device to keep the pressure in the system within desired limits through by-passing water from the turbine case or lower penstock. The surge tank, either simple or differential, is a reserve capacity used to store or supply water during periods of governor operation to maintain pressure in the penstock within prescribed magnitudes.

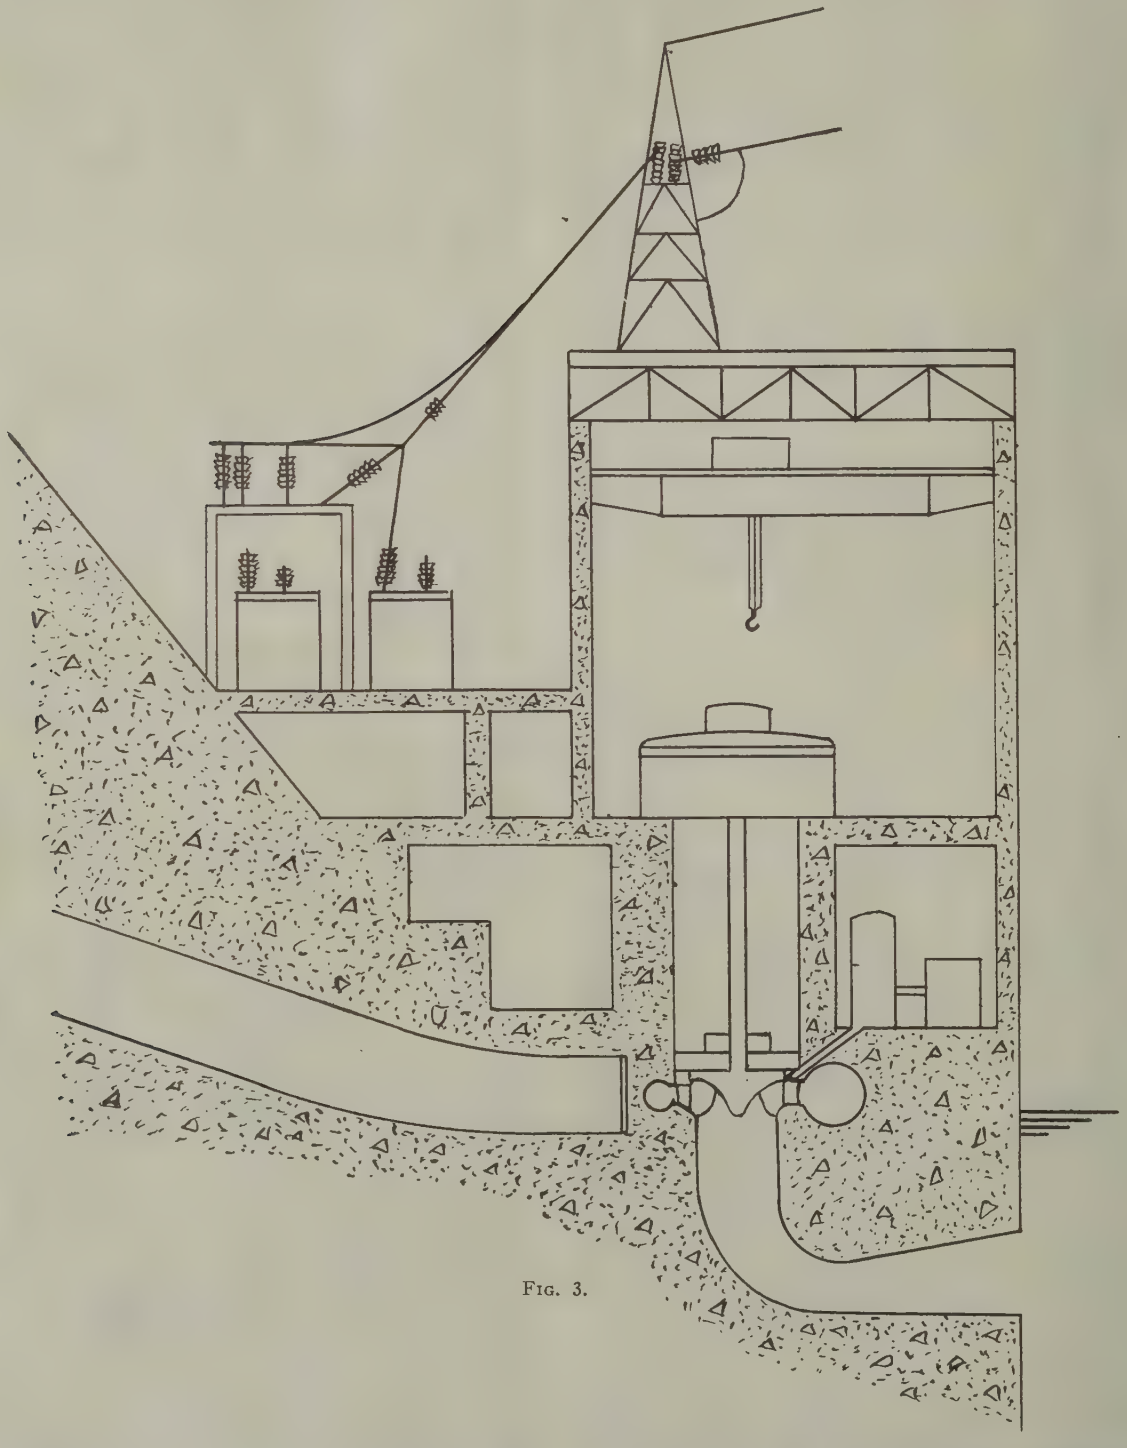

Fig. 3.

Water power plants with water wheels as the prime mover have been in existence for centuries. Such wheels make use of the velocity of the water flowing in a river (much the same as a windmill obtains energy due to the velocity of the wind) or an elevation drop in the water surface about equal to the diameter of the wheel. In both cases the power generated is limited severely and was found adequate only for small mechanical powers to be utilized on or very near the location of the water wheel. Examples include such installations as power for gristmills or power for operation of mechanical equipment in a manufacturing plant by transmission through gears or belting to separate locations desired. The hydraulic turbine is the prime mover for modern water power developments. Turbines were introduced and developed during the 19th century in Europe and America. Early European construction tended to conform to the results of analytical design

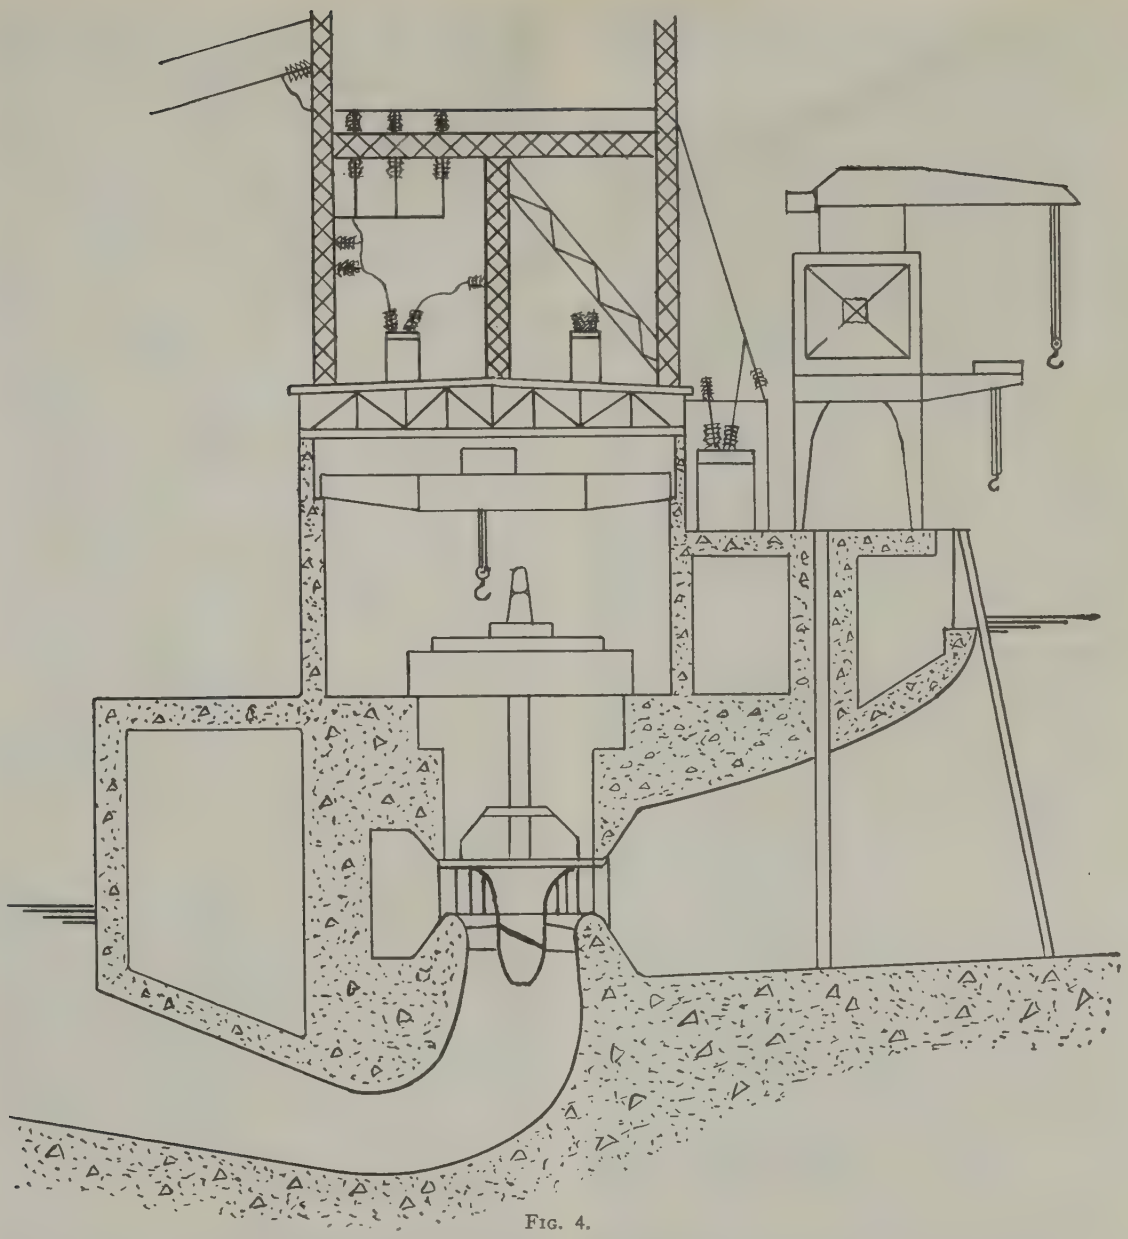

FIG. 4.

studies while American units were the result, to a large extent, of trial and error empirical methods. Since about 1900, all turbines of a given type illustrate striking similarities in design due to intelligent blending of experience from theoretical and experimental sources. By 1920, the Francis type of reaction turbines in large sizes had attained maximum efficiencies in the range of 92 to 94 per cent. By 1940, propeller type reaction and impulse turbines reached maximum efficiencies of 90 per cent and above. These high turbine efficiencies combined with large size and dependable operation with corresponding developments in electrical generators and electrical power distribution systems have made possible the rapid growth of hydroelectric plants during the last half century. Many types of turbines have been constructed but modern commercial units are limited to three types which are known by the name of the principal inventor as well as by the basic physical principle of their operation. The range of application of each type is expressed best in terms of the specific speed defined as the ratio of the product of the speed of shaft rotation (revolutions per minute) and the square root of the horsepower output to the hydraulic head (feet of water) raised to the five fourths power. The table presents the classifications:

Principal inventor	Physical principle	Range specific speed for maximum efficiency
Pelton	Impluse	3.5 to 5.5 *
Francis, James B. (1815–1892)	Reaction	15 to 100
Kaplan	Propeller (axial flow)	90 to 190

* Range for Pelton water wheel with a single nozzle.

All turbines are installed with either horizontal or vertical shafts but the majority of larger installations use horizontal shafts for Pelton wheels and vertical shafts for Francis and Kaplan turbines.

The powerhouse provides protection for the important mechanical and electrical equipment of a water power development. The turbo-generator unit is usually housed for protection against the

weather and to increase the ease of maintenance. In temperate climates, these units may be installed out-of-doors. Switching and transformer facilities are required to handle the electrical power between the generator and the high voltage transmission line. Many stations are constructed with transformer and high tension switching equipment outdoors. Automatic control equipment, operator's control panel, instruments, low tension switching equipment, maintenance shops, office, and storage for supplies are typical items included within the powerhouse. Space and hoisting equipment must be provided for installation, repair and maintenance of the hydraulic turbine and electrical generator units. Normally one or more operators are on duty at the powerhouse but some fully automatic hydroelectric plants only require a maintenance visit and check at infrequent intervals like a week or longer.

Figs. 2, 3 and 4 illustrate various typical hydroelectric station arrangements. Fig. 2 shows a single nozzle horizontal shaft impulse turbine. Units of this type are used for heads of 1,000 feet and greater and in sizes up to about 70,000 horsepower. Most installations use one or two nozzles per wheel but recent developments include efficient operation with four and six nozzles per wheel. The penstock terminates in a needle nozzle which is automatically adjusted by the governor to maintain constant rotative speed of the wheel. The nozzle guides the high velocity water into the buckets mounted on the wheel where the water is deflected in such a fashion that the forward component of velocity approaches zero. The water then falls from the housing and passes into the tail pit. In this illustration all important elements are inside of the powerhouse.

Fig. 3 shows a vertical shaft Francis turbine mounted in a semi-outdoor type of powerhouse located at the base of the dam. Water flows from the conduit through the dam into the spiral case, through the wicket gates, the runner, and the draft tube. The wicket gates are adjusted by governor action to maintain constant speed of rotation. These turbines have been constructed for use with heads between 3 and 1,000 feet, but modern designs are seldom used for heads of less than 50 feet. One of the larger American units is rated at 115,000 horsepower at 475 foot head and 180 revolutions per second.

Fig. 4 illustrates a low head installation with a vertical shaft propeller turbine. Water from the reservoir passes through the trash racks and intake gate into the spiral case and through the wicket gates, propeller, and draft tube into the tailrace. The semi-outdoor type of powerhouse includes crane facilities for cleaning the trash racks. Control of speed of rotation is obtained by governor action of the wicket gates and in some cases the angle of blade setting of the propeller is adjusted also. The units are designed for heads of a few feet up to about 75 feet. One of the larger American units is a 23.3 foot diameter propeller rated at 60,000 horsepower at 69 foot head.

At isolated localities on farms, in mines, lumber mills and similar installations, consideration is frequently given to the establishment of a small water power plant when a stream or large spring as a water supply is readily accessible. Usually competent engineering advice is not obtained as the total expenditure is small and lower first costs are of primary importance. The mechanical work or electrical power output of such a plant may be quite low and yet the user will be satisfied. With the assumption that the usable output is about fifty per cent of the theoretical power available in the water, it takes about 400 gallons per minute through an elevation drop of 20 feet to generate one horsepower. If the head drop is increased, the water required reduces in the inverse ratio and vice versa. To generate more power, the head, water rate, or the product of the two must be increased in the same ratio as the power. A limited number of companies produce small turbines on a standard model basis. The prospective user of small turbines will do well to investigate the application of standard centrifugal pumps in reverse flow and reverse rotation as a suitable prime mover. Suitable pumps will achieve efficiencies of 85 to 90 per cent operating as turbines. The most flexible type of pump for this service is the vertical deepwell turbine (in Europe this is known as a borehole pump) unit, since stages are added or subtracted easily. In large size units, pumped storage systems have made use of a single centrifugal machine as the pump and hydraulic turbine. During period of low power usage on a power system, the excess power is used to pump water from one reservoir to another at a higher elevation and when additional power is needed, the water returns to the lower reservoir by passing through a hydraulic turbine.

Chairman, Division of Mechanical Engineering, College of Engineering, University of California.

WATER PURIFICATION. See Water Supply; Waterworks.

WATER RAIL, a species of rail (*Rallus aquaticus*) widely distributed over Europe, Asia and North Africa and generally common, but, on account of its retiring habits and shyness, not often seen. It is about 11 inches long, olive brown above streaked with black, the under parts gray and the sides streaked. It frequents marshes and bogs, dives and swims well, but is a poor flyer. It is a delicious tablebird. In North America its nearest representative is the king rail (*R. elegans*).

WATER RIGHTS. See Rivers; Riparian Rights.

WATER SCORPION. See Fresh-Water Insects.

WATER SNAKE, a harmless colubrine American snake (*Natrix fasciata*), closely allied to the garter snakes, but of aquatic habits, swimming and diving with great ease and skill and spending its life largely in streams, ponds and marshes. It lives largely upon fish, either alive or dead, frogs, tadpoles, newts and aquatic insects and other small creatures. It is mottled in variable dull tints and is lively and pugnacious. Its eggs are laid in holes in stream banks and similar places. The common grass snake of Europe, the only British serpent except the viper, is a near relative.

WATER SUPPLY (for Public and Industrial Consumption, Including Its Uses, Sources, Transmission, Treatment, Conservation and Distribution).—Introduction.—This article does not treat of aqueducts, dams, drainage, flood control, hydraulics, hydrology, irrigation, power de-

velopment, rainfall, pumps, transpiration, tunnels or sewerage; *see* articles with these titles for treatment of these aspects of control of water. This article deals with the methods and equipment required to collect, conserve, and deliver to consumers a potable, conditioned product, acceptable to both domestic and industrial users as to quantity, quality and pressures. Quality is important for most uses except street flushing, sewer flushing and fire fighting. John Ray, the 17th century English naturalist advises: "Foul water will quench fire." (*English Proverbs*).

When primitive man found that his land was unfit for producing water from wells, he joined his tribal brethren in a communal enterprise to put down a well, or convey surface water in channels, where all could get water. An early instance of a community well is recorded in the 26th chapter of Genesis; the herdsmen of Isaac struggled with the natives of the valley of Gerar, for the possession of wells in the valley, one of which is reputed dug by Abraham, but filled up by the Philistines. Some centuries later Hezekiah "made a pool, and a conduit and brought water into the city" of Jerusalem (II Kings: 20, 20). The woman of Samaria (John 4: 7) drew water from a public well donated centuries before by Jacob.

Pliny, the Younger, who had been connected with public works in Rome in the 1st century A.D. and who was a friend of Frontinus, the author of a treatise on the water supply of Rome, praised the early artisans: "If we only take into consideration the abundant supply of water to the public, for baths, ponds, canals, household purposes, gardens, places in the suburbs, and villas; and then reflect upon the distances that are traversed, the arches that have been constructed, the mountains that have been pierced, the valleys that have been filled up, we must of necessity admit that there is nothing to be found more worthy of our admiration throughout the whole universe." The conduits of the Romans were of the gravity type, perforce, as they antedated by centuries the invention of pumps, and of pipes that could withstand necessary pressures.

Similarly, of remote antiquity is the appreciation of the relation of the drinking-water supply to disease. In the 4th century before Christ, Hippocrates, termed the Father of Medicine, advocated the boiling and filtering of polluted water before drinking. Pliny, the Elder, in his Natural History (about 70 A.D.) discusses the characteristics of potable water. Water treatment may have originated in China, or India, thousands of years ago. From olden times, the Chinese were accustomed to putting alum in tubs of water to clarify it. The same thing was done in Egypt. Elisha is recorded in II Kings 2: 19-22 as treating a worthless water ("the water is naught") with salt so that it became usable "unto this day." This probably occurred in the reign of Jehosophat about 900 B.C.

The treatment of water to remove pathogenic organisms which are prevalent in many natural sources of water supply after pollution by man, had its beginning about 1892, after Dr. Robert Koch had traced the cholera epidemic in Hamburg, Germany, to its unfiltered raw water supply, by observing that Altona, on the opposite bank of the Elbe, which used the same river water, but filtered it, had no cholera. Previously, since 1855, London had been required by parliamentary statute, to filter its water supply through slow sand filters, but the efficacy of the process was clearly demonstrated by Dr. Koch. Filters were not introduced in America until about 1870 and were of the slow type; the first important modern rapid-sand filtration plant was built in 1902 at Little Falls, New Jersey, and is still used by the Passaic Valley Water Commission.

In 1912, liquid chlorine was developed for the disinfection of water supplies, and the subsequent development of modern equipment for its automatic application has made this procedure standard practice for combatting pathogenic bacteria, with less and less reliance being placed on other treatment processes.

Use and Consumption of Water.—This article deals only with water diverted into waterworks structures, and not with the use of water in its natural channels, where it is beneficial for fishing, shell-fish culture, bathing, boating, navigation, power development, irrigation, and disposal of sewage and wastes by dilution. The uses of water from waterworks are classified by Phelps and Velz [1] as (1) primary, which serve such strictly domestic purposes as drinking, preparation of foods and beverages, bathing, cleansing, and hose-sprinkling of lawns and kitchen gardens; and (2) secondary, which comprise industrial processes, commercial products, watercarriage of wastes in sewers, fire fighting, street sprinkling, swimming pools, and public fountains. Velz finds for a composite community (residential, commercial and industrial, in normal proportions) the reasonable requirements in gallons per capita of resident population per day, to be: residential, 40; commercial, 15; industrial, 30; public, 10; unaccounted for losses, 15; a total of 110. He estimates that the 40 for residential can be cut to a bare necessity of 20, by using 4 for drinking and culinary, 6 for laundry, 5 for bathing, and 5 for two toilet flushings per day. Caleb Mills Saville found in Hartford that a rate of 9 was possible in houses lacking plumbing, but he sets 25 as the minimum in a residential community: "Certainly a minimum of 25 gallons per capita is insufficient to maintain the standard of living desired in most American communities." *

Capen [2] derived from his studies the following relation of population to use:

For completely-metered low-waste systems, $G = 53\ P^{0.11}$

For well-metered average systems, $G = 54\ P^{0.125}$ where G is gallons per capita per day, and P is population in thousands.

Hopkins and Elder [3] conclude that in the larger American cities where industrial demands are heavy, rates (gallons per day per capita) vary from 90 to 300; while in smaller residential communities where industries are a minor factor, they vary from 40 to 140. They deduce from the 1945 inventory made by the Public Health Service of 15,370 water utilities in the United States that the average is 127, varying from 50 to 400; from this same inventory, Langbein brings out the increase of rate with the size of the community: [4]

Population	Gallons per day per capita
500	60
1,000	85
5,000	135
10,000	140
50,000	140
100,000	140

* For footnote references 1-18 consult list of footnotes at end of this article.

Unaccounted for water, which passes through the master meters at the source of supply, but not the meters of the consumers who pay the bills, constitutes 20 to 50 per cent of the master-meter reading. It comprises water lost in leakage in pipes and services, and water used for street sprinkling, snow removal, sewer flushing and fire fighting. Although water must be delivered at high rate of flow for fire fighting, and pumps, tanks and pipes must be proportioned for this high rate, the total quantity so used in a year is insignificant compared to the normal demands. Wegmann [5] lists the rates and quantities used at notable fires. Velz estimates the maximum daily demand over a period of years, as 150 to 200 per cent of the yearly average, and the hourly peak rate at 200 to 300 per cent, dependent on lawn sprinkling, shower baths and air conditioning. As to seasonal changes, he estimates summer at 120 to 140 per cent of the yearly average, and winter at 70 to 90 per cent. As to any one normal day, he estimates the minimum (early morning) use at 40 to 70 per cent of the day's average, and the forenoon maximum at 120 to 170 per cent.

Business depressions have a more pronounced effect on the industrial than on the total consumption. At Newark, New Jersey, in the year of prosperity, 1929, the total rate was 59.1 million gallons per day (mgd.), of which 16.1 was industrial. During the depression, in the year 1932, the total dropped off 14.7 per cent, to 50.4, while industrial demand dropped off 37.5 per cent, to 9.9.

Of recent years, the water requirements of the rapidly growing air conditioning installations have become so heavy that many municipalities passed strict ordinances governing this special use of water and most of them require the recirculation of such water. For instance, a 10-horsepower compressor requires about 1,000 gallons per 8-hour day. Waterworks officials at Quincy, Ill., estimate peak loads have been raised 15 per cent, while at Phoenix, Ariz., the estimate is 100. For a brief discussion of air conditioning physics, see Henderson.[6] In 1950, a committee of the American Water Works Association found that water-cooled refrigeration "involves the use of water in quantities never before anticipated, thereby placing unexpected burdens on the public water supply system which are detrimental to other classes of water services," and calls for regulatory ordinances. On Long Island, by state law, all cooling water has to be returned to the ground through special diffusion wells sunk by the applicant. In New York City all air conditioning using water at a rate of 5 gallons per minute or greater, must be equipped with a water-conserving unit, such as a recirculating device, or a cooling tower. In Philadelphia, Pa., economizers are required where the rate exceeds 10 cubic feet per minute (75 gallons). Among other communities regulating the use of public water for air conditioning, are Champaign and Urbana, Ill., Rochester, N Y., Richmond. Va., Kenosha, Wis., Reno, Nev., and Washington, D.C.

The effect of pressure on consumption is direct; high pressures induce leakage, and freer domestic use. When the pressure at Oak Park, Illinois, was reduced from 45 to 25 pounds, the consumption rate fell from 65 to 45 gallons per capita per day.[7]

Undue use of water proves a serious consideration when it requires the municipality to seek additional sources, or install larger pumps and pipes. It can be curbed by public appeal and ordinances prohibiting the use of water for lawn-sprinkling and other purposes, in the emergency, by waste surveys, and by the installation of meters. When the New York City reservoirs dropped to an unprecedented low in December 1949, reform measures were instituted; prohibitions issued by the Department of Water Supply, Gas and Electricity, banned automobile washing, operating hoses, constant-flow showers, constant or periodic-flow flushometers, swimming pools, sprinklers, ice-skating rinks, etc. "Dry Thursdays" were observed (no bath, no shave) and the shortage kept daily in the public eye by newspaper, radio, and television, whose response was so effective that consumption was cut from 1,232 million gallons per day in December 1949 to 966 million gallons per day. On Sept. 14, 1950, when fortuitous rainfall had replenished the reservoirs, the bans were lifted. Surveys for waste abatement are routine procedure in large cities; a separate division was set up in the Bureau of Water in New York City. Water may escape in the street or on the owner's premises from defective joints, broken or cracked pipes; water may be wasted by defective plumbing fixtures; and by individuals who open faucets in cold weather to prevent freezing of pipes. Waste surveys in Detroit reported by Hardenbergh [8] indicated a loss of 3,000 gallons per day per mile, or 5 per cent of the pumped supply; in Chicago, 13½ per cent loss was reported, and in Philadelphia, before remedial measures were undertaken, it was 13 per cent. Hardenbergh estimates it impracticable to reduce leakage much below 1,500 gallons per day per mile, and it may reasonably be 3,000 on large pipes; he recommends that design of systems contain an allowance of 3 to 10 gallons per day per capita for uncontrollable waste.

The installation of house meters on an extensive scale confronts owners with their personal responsibility for the quantity of water used and soon produces a marked reduction in the consumption. But as the novelty of responsibility wears off, the rate of consumption starts to rise, although less rapidly than prior to installation. When the owners begin to check up on leaky fixtures, and unnecessary use of water, the rate drops for a year or two. Many large cities, such as New York, require meters only of industries, commercial establishments, and large apartment houses; the opponents of meters—and there are not a few—emphasize both the cost, and the nuisance, to the householder of meter reading and replacement, and the expense of installation. There is, too, considerable loss of pressure through the meter. On the other hand, a universally-metered system such as that in Boston provides for costs allocated according to benefits, the smaller user paying directly proportionally less, beyond the minimum termed the flat-rate, which is based on the size of the service; for instance, the Hackensack Water Company charges $2.25 per quarter for a ¾-inch meter.

Sources and Collection.—Hydrological conditions as to rainfall, run-off and percolation must be understood in developing and collecting a water supply Rainfall infiltrates into the soil, runs off over the surface, or is transpired by vegetation; evaporation follows; then condensation into cloud formation, and return to earth as rain or snow; this is known as the *hydrologic*

cycle. Although precipitation (see article on RAINFALL) is the source of all water supply, only a small part is divertible by man to his uses, since less than half of it appears promptly as stream flow, the remainder undergoing either percolation into the porous substrata, transpiration from vegetation, or evaporation from land and water surfaces. Sky water which undergoes evaporation and transpiration is not available in the immediate phase of the hydrologic cycle for man's use. On Long Island, where there are no surface streams of fresh water of any appreciable size, all water supplies are derived from the ground-water, rain-water which has percolated into the porous substrata. It has been found by the water works officials on the island that the safe yield of the aquifers is about one half the rainfall, the rest running off to sea over or through the ground, or lost through evaporation and transpiration.

Underground waters are found more feasible in small communities, while large cities, with a few exceptions, either go great distances for upland surface supplies, or utilize the large lakes or rivers on whose shores they were founded. Langbein, hydraulic engineer of the United States Geological Survey, deduces from the 1945 inventory of *Water Facilities in the United States,* by United States Public Health Service, that 70 per cent of the population were served by 15,400 public or private water supply systems. Ground waters were the source of 76 per cent of the systems, while 24 per cent used surface waters.[9]

But the ground water systems accounted for only 26 per cent of the water used, while the surface-water sources took 74 per cent. This is explainable by the fact that ground water resources lie near at hand and are cheap to install, while surface supplies can only be afforded by the largest cities, as they entail expensive reservoirs and aqueducts, or large offshore intakes, and expensive tunnels to the pumping station.

The method of development of sources to produce a dependable yield varies with the type of source: (a) in the case of liquid streams, it involves a large impounding reservoir to develop the safe yield of the stream, intake works (commonly termed "headworks"), and a transmission conduit between the reservoir and the community; (b) for surface supplies taken from lakes and rivers, of such large size that storage for dry periods is not required, it involves intake works, a subaqueous conduit, a pumping station, and a force main to the distribution system, and perhaps distribution reservoirs and booster pumps on the distribution system; (c) in the case of ground water, it involves wells, infiltration galleries of springs, distribution reservoirs to prevent overpumping the source, and pumps either in the wells, or on the surface.

Surface waters and ground waters can only be made available by constructing waterworks. If the sources of supply are large rivers, as in the case of St. Louis, Philadelphia, and Kansas City, or from the Great Lakes, as at Buffalo, Cleveland, and Chicago, intake structures are designed only to obtain water of the best quality, and no thought need be taken of lack of water in dry years. But where the supply is dependent on large reservoirs on upland streams of variable flow, as at Boston, New York and San Francisco, consideration must be given to the amount of runoff which can be caught in the reservoirs and held for use during a series of dry years. Impounding reservoirs must be built on streams in the highlands to store water during freshet flows, for use when the natural flow of the streams is insufficient to meet the demand. Impounding reservoirs are formed by throwing a dam across a narrow valley and just downstream from a region where the valley has a wide floor, to afford large storage for minimum cost of dam.

The capacity to be developed in a proposed impounding reservoir will require statistical, economic, hydraulic and hydrological studies. Statistics will reveal the past records on which future rates of demand must be predicated. Economic studies will entail the correlative costs of dams of various heights as compared to the storage capacity secured and the real estate to be acquired to safeguard property just outside the flow-line from pollution, and the clearing and possible grubbing of the site. Hydraulic studies will fix the flow-line of the depleted reservoir high enough so that the distribution system can be largely fed by gravity, and the transmission conduit between source and municipality will be the smallest possible. Hydrological investigations, on this and comparable watersheds, will provide bases for estimating the stream flows in dry seasons, and the consequent drafts from the reservoir; also for estimating flood flows, for which the spillway must be proportioned; this class of investigations is most susceptible to errors in judgment, since reservoirs are generally projected on small unimportant streams where real estate is cheap, and on such streams, no direct records are available. Hazen's[10] method of utilizing data from comparable streams affords the quickest approximate method of fitting the reservoir capacity to the expected flow. The function of the hydrological studies is primarily to arrive at an estimate of the safe yield of a project. Safe yield is defined as "the maximum dependable draft which can be made continuously upon a source of water (surface or underground) during a period of years during which the probable driest period or period of greatest deficiency in water supply is likely to occur."

Not all storage behind an immense dam is available for use; the lowest outlet port in the headworks leading to the transmission conduit is located several feet above the bottom of the reservoir, to avoid discharging silt into the conduit. Allowances must be made, particularly in the West, for the gradual siltation of the reservoir, which may, over a term of years, reduce its available capacity; for instance the designers of Elephant Butte reservoir in 1916 estimated that it will silt up in about 233 years. Evaporation must be considered in reckoning on the available storage, since the evaporation from water surfaces in a year in the vicinity of New York, is about equal to the rainfall; if there were no rainfall, the water surface would drop 4 feet in a year due to evaporation alone. The City of New York operates its series of Croton and Catskill reservoirs on the basis of always leaving 25 per cent in storage for emergency use in a year drier than any yet experienced; in the unprecedented crisis of 1949–1950, the city managed never to draw the reservoirs down to the 25 per cent margin; 37 per cent was the lowest point reached Dec. 1, 1949.

Intakes on impounding reservoirs may be located in the dam as at Ashokan reservoir, in which case they are termed "headworks," or at another point on the reservoirs, as at Schoharie

reservoir, both on the Catskill system, New York City. Since the quality of water at various depths in such large bodies of water varies from month to month, and the water level may vary with the dryness and demand, effluent ports must be provided at several levels. Valves must also be provided to let compensation water pass downstream to satisfy the dry weather flow of lower riparian owners, and for emptying the reservoir to a desired minimum. Generally, it is inexpedient to locate valves at the extreme bottom of the reservoir, as they would soon be buried in the silt. Screens and stop logs are necessary (see section *Intake Works* below).

The development of supplies from large bodies of water requires investigation as to the least polluted areas for locating the intake, and studies of offshore winds which would carry pollution to the intake; in the case of rivers, hydrological investigations are necessary to assure that the dry-weather flow will satisfy in future years, both the proposed water-taker, and riparian owners downstream.

The development of ground waters requires a series of test wells, and test pumping, to reveal the best site, how closely wells may be spaced, and the levels of the aquifers. The Jamaica Water Supply Company on Long Island has wells spaced as closely as 50 feet but drawing from three different aquifers, at depths of 100, 250 and 600 feet.

Intake Works.—Intake works are essential on reservoirs, lakes or large rivers to divert the required quantity of water into the transmission conduits or suction wells of the waterworks system. They are generally equipped with inlet and outlet gates, or stop-logs as an alternate; coarse screens to exclude cumbersome floating objects which would damage the conduit and pumps; and in cold climates heating devices for the screens to prevent ice from plugging the waterways. It is important to install the intake in deep water, with valved inlet ports at varying levels, so that valves can be operated to select the level at which the water is of best quality. Intakes of the tower type are used at Chicago, where there are five, and at Cincinnati. (See *Engineering News Record,* May 22, 1930, p. 834.) The latter extends to sufficient height to allow for a 70-foot variation in the stage of the Ohio River. Tower intakes require night lighting to warn marine and aerial navigation.

Submerged intake cribs of the type used at Gary, Indiana, contain no valves or screens, such operating devices being placed at the shore end of the intake conduit. Intakes of this kind should not project above the bed of the lake far enough to endanger navigation. Cleveland has a new submerged steel intake with its top 41 feet below low-water level (*Engineering News Record,* Aug. 5, 1948, p. 76).

In both types of intakes, it is advisable to build the entrance ports large enough so that the entering velocity is less than 1 foot per second, to minimize the quantity of sediment, fish and anchor ice carried into the intake.

The intake conduit from the deep-water intake to the shore may be a tunnel as at Chicago and Cleveland, a 10-foot diameter reinforced-concrete pipe as in the new Cleveland intake, steel pipe as at Rochester, or cast-iron pipe as at Cedar Rapids.

Works for the collection of underground waters may be springs, infiltration galleries or wells of several types: large open, driven, drilled, and gravel-packed. For years, Roanoke, Va., got most of its water from a spring in rock formations; Havana, Cuba, gets most of its supply from the Vento Spring in limestone formation; New York City operates the infiltration gallery at Wantagh, Long Island, over 5 miles long and yielding 30 mgd. Wells in consolidated formations constitute the most common method of utilizing shallow or deep supplies. Wells are used also in rock formations, as at Madison, Wis. At comparatively small cost, a well can be put down to utilize water resources at any reasonable depth. In calculating the spacing of wells, consideration must be given to the drawdown curve of each well, caused by the rapid withdrawal of water by the pump, which will cause wells too closely spaced to yield less than the anticipated quantities; this circle of influence may extend for several thousand feet in porous formations, and less in tighter soils.

Water supplies for single farms or homes can generally be obtained from a shallow dug or driven well, at little expense, but the purity must be properly safeguarded, by sealing the top of the well against pollution from the surface. Ordinarily, drilled wells in unconsolidated formations comprise a hole cased with a pipe to prevent caving, and having at its lower end a screen to keep out sand. Since it is impracticable to make the screen openings small enough to keep out the finest sand, and yet large enough to admit the desired quantity of water, it is common practice to remove the fine sand within movable distance of the screen, by pumping the well to waste for several days at an excessive rate, so that the fine sand will be washed out of the interstices of the gravel next to the screen, where the converging waters have velocities sufficient to move sand, so that when the well is pumped at normal rates, little if any fine sand will enter the screen. This process is termed "development of the well." Where water is to be obtained from a fine-sand layer, as on Long Island, the gravel-packed or gravel-wall well has been found most advantageous in assuring uninterrupted flow, since an ordinary well in this material would clog readily. This type of well is double cased, the ground opposite the screen is underreamed, and the space filled with pea gravel poured down between the casings, which space is afterwards sealed off with mortar. This type brings less sand into the well during years of operation.

Rock wells are the chief source of underground water in the north central states, Ohio to North Dakota. Madison, Wisconsin (*Water Works Engineering,* June 1951) is an outstanding example of a population of 100,000 supplied entirely from rock wells. The first wells were put down in 1881; 22 wells have been drilled to depths varying from 500 to 2,000 feet, to tap the same water-bearing rock known as Potsdam sandstone. The overburden varies from 10 to 250 feet. Ten wells have been abandoned for various reasons: hydrogen sulphide gas, capacity too small, poor location relative to growth of city, high in iron from upper rock layers (these layers were cased off in later wells and corrected this trouble). The present 12 wells yield an average of 25 million gallons per day (mgd.). They are widely spaced around a 25 mile circuit.

Ground water supplies, in comparison with surface waters, require continual vigilance for their conservation as to quantity, pumping level,

quality, and condition of the screens and casings. Close spacing may reduce the quantity per well, over-pumping may cause the static level to drop, as at Houston where it dropped 120 feet over a term of years. Encroachment of homes and industries may bring pollution problems. In Nassau County, Long Island, a dump for garbage and rubbish, including old auto bodies, raised the iron content of a shallow well several hundred feet away to such an extent that the well had to be deepened to a water-bearing formation where the surface pollution had not penetrated, perhaps due to the tight clay lenses which separate various water horizons on Long Island. Wearings of screens and pumps by sand often shorten the lives and reduce the yield of wells.

CONDUITS

The conveyance of water supply from an impounding reservoir to the distribution system entails the construction of conduits of some form: canals or open channels, large masonry aqueducts or pressure tunnels (see article on AQUEDUCTS), or metal or reinforced concrete pipes. The ancients had no materials available to withstand high pressures, so they had to content themselves with masonry aqueducts following the topography, with aqueduct bridges across valleys. But, in modern waterworks, with a wide choice of materials, equipment and skills, the engineer places less dependence on topographical considerations, and is free to adapt the procedure to the physical conditions, and can utilize canals, pipe lines of wood, metal, reinforced concrete and asbestos-cement, cut-and-cover concrete masonry, grade and pressure tunnels, siphons, and even, as in the case of the Colorado River aqueduct, incorporate in the project booster stations and force mains. The economical combination of these various types is represented in the Catskill aqueduct of New York City, which contains cut-and-cover aqueducts, grade tunnels, pressure tunnels, steel-pipe siphons, some reinforced concrete monolithic aqueducts, and a dual cast-iron pipeline under the Narrows in New York Harbor.

Reinforced concrete conduits may be monolithic or precast. Precast pipe is not obtainable in sizes above 120 inches. Steel cylinder pipe is recommended where the head exceeds 100 feet; it is manufactured under patents by Lock Joint Pipe Co. The hydraulic carrying capacity of concrete, asbestos-cement, or cement-lined metal pipes does not deteriorate as rapidly as with tar-coated metal pipe. However, slimes will build up in such pipes and reduce the carrying capacity.

In the last quarter of the 19th century, a great deal of wood-stave pipe was used, as it was cheaper than iron or steel and maintained a high carrying capacity, but it was found, as at Atlantic City and Norfolk, to have a relatively short life.

For high heads, and where water hammer is a dominant factor, plate steel with modern welded shop joints, and Dresser couplings for field joints, produces a satisfactory conduit. Conduits should be safeguarded against tuberculation by cement-mortar lining, bituminous coating, or cathodic protection. As compared to cast-iron pipe in sizes above 48 inches, steel pipe is cheaper, and is damaged to a lesser extent by blowouts. But it must be protected against collapse by air-and-vacuum valves.

Cast-iron pipes are used for conduits in sizes up to about 48 inches. The modern tendency is to use centrifugally-cast pipe which is lighter in weight than pit-cast, and comes in 20-foot lengths. Where waters are active, the pipe should be cement-lined to guard against loss of capacity by tuberculation.

Appurtenances essential to the successful operation of transmission conduits include, high-level overflows on flow-line aqueducts; sectionalizing valves or stop planks at convenient intervals, so that sections may be taken out of service without too much loss of water or damage by water to adjacent property; blowoffs at convenient stream crossings for emptying sections for repairs and inspection; air valves on summits of all pressure lines; drainage shafts and blowoffs on pressure tunnels; air and vacuum valves on all steel pipelines.

The size of conduits from distant reservoirs can be reduced, and continuity of service can be better insured, if distribution reservoirs (see below) are installed on the distribution system, to provide for hourly and daily peak rates of demand, or several days' storage in case of a break in the transmission conduit.

The waterworks system of Kingston, N. Y. is typical of the utilization of service storage in assuring continuity of supply at adequate pressures without expending more money for transmission conduits. Cooper Lake, the impounding reservoir in the Catskill Mountains, is 14 miles northwest of Kingston and at a satisfactory elevation for gravity flow through a pressure filter plant located 6 miles from the city. For a score of years, an attempt was made to meet all demands of the municipality by momentary changes in the rates of pressure filtration. This proved unreliable so a storage reservoir, which could be filled by gravity flow, was built at an economical high point midway between the filters and the city. During the next 10 years, Kingston continued to expand to the hillsides at the west. It was found that at times of peak demand (lawn sprinkling and shower baths on hot days) the existing transmission conduits from the equalizing reservoir (an 18-inch pipe laid in 1883, a 20-inch pipe laid in 1895, and a 20-inch pipe laid partly in 1914 and partly in 1926) could not supply water to the high points at satisfactory pressure. Therefore, in 1938, the "West Side" standpipe was built, with its flow line at the same elevation as the equalizing reservoir. It is situated on the opposite side of the distribution system from the point of connection of the three transmission conduits, and is connected to the distribution system by a 16-inch cement-lined cast-iron pipe. Obviously, this 1,000,000 gallon standpipe which is 40 feet high to full level, cannot be completely filled by gravity flow from the equalizing reservoir; it was necessary, therefore, to install an automatically controlled pump, which would pump water in the early morning hours (the time of least demand) from the distribution system to fill the standpipe. (This installation is described in *Public Works,* February 1928).

PUMPING SYSTEMS

For the various kinds of water works pumps, and particularly triple-expansion reciprocating pumps and motor-driven centrifugal pumps, see article on PUMPS AND PUMPING MACHINERY. Deep wells are generally equipped with motor-driven turbine pumps; closely spaced groups of shallow wells, if the pumping depth is less than 20 feet, can sometimes be connected to a common

suction header, and served by a pumping station at ground level. The Jamaica Water Supply Company, Jamaica, Long Island had two stations, comprising about a dozen wells each, which operated successfully for years, but they had to be abandoned due to various causes, not the least important the gradual recession of the pumping level. Wells can be pumped directly into the system, but this leads to over-pumping of the stratum during periods of high demand; a more conservative practice is to pump at a low constant rate from the well to a tank at ground level, whence water is boosted by other pumps to meet the fluctuating rates of demand.

The choice between steam and electricity for power depends on many factors. Electricity is essential for automatic or semi-automatic operation. Power failures must be guarded against with electricity by providing gasoline or Diesel engine stand-bys.

Three types of pumping systems are in use in this country: direct, indirect, and direct-indirect. In direct pumping, there is no open reservoir on the distribution system, and the pressure at the pumps depends on the number of taps open; water hammer is a constant menace, and fire demands can be met only by speeding up the pumps to raise the pressure. In indirect pumping, an open storage reservoir is provided between the pumping station and the distribution system, into which all water is pumped, before it flows by gravity to the distribution system; this allows the use of constant speed pumps, and eliminates water hammer on the pumps, but water hammer might still menace plumbing fixtures. In direct-indirect pumping, an open storage reservoir is located on the far side of the distribution system, allowing the pumps to operate against fairly constant pressure; there is no water hammer on pumps or plumbing fixtures. Fire demands can best be met by this system, whereby double the quantity is available, and at higher pressures. Smaller pumps, and reduced power charges, are possible with this system.

STORAGE IN DISTRIBUTION RESERVOIRS

Impounding reservoirs, discussed above, are situated only at the source of surface supplies, whereas distribution reservoirs (also termed "equalizing" or "service" reservoirs) are utilized in connection with both surface supplies (lakes or reservoirs) and ground water supplies, to insure adequate service to consumers in all foreseeable emergencies. They are located close to, in the midst of, or on that side of the distribution system, opposite to the conduit from the source of supply. They serve numerous useful purposes: (1) on indirect, or direct-indirect pumping systems, distribution reservoirs provide a cushion against which the pumps react, and in turn are operated more evenly, thereby eliminating water hammer hazards; (2) where wells are the sole source of supply, distribution reservoirs provide storage to meet hourly and daily peak demands, and conserve the ground water supply by allowing the well pumps to be operated at a slower rate, so that water is withdrawn from the aquifer in quantities unlikely to cause recession of the water table, or inflow of undesirable water; (3) by providing an emergency reserve, they lessen the damages and discomfort consequent on a break in a supply conduit, failure of wells, pumps or power, or flooding of pumps or wells; (4) they insure the supply of water at better pressures than that supplied by long transmission conduits, or by direct pumping systems, thereby postponing the need of larger conduits or additional pumps; (5) in hilly terrain, the distribution system can be zoned by elevations, each zone being serviced by a distribution system reservoir, and perhaps a booster pump; (6) the reserve storage in distribution reservoirs makes it possible to design transmission conduits, wells, pumps, etc. for the average rather than the peak demand rate, at marked economy; (7) on small systems the distribution reservoirs can be filled during the 8-hour day, or during periods of low-priced power, thereby saving 2 labor shifts, and considerable power; (8) where the supply is filtered, the storage in distribution reservoirs allows the operation of the filters at normal rather than peak demand rates, thereby saving wash-water, power and wear-and-tear; (9) distribution storage provides for peak rates of fire flow required by the National Board of Fire Underwriters more economically than extra pumps or supplementary distribution pipes.

In large cities, fire demands do not predominate and the required storage is a matter of judgment respecting the hazards involved in event of interruption of supply through failure of the transmission conduit, pumps, or wells. According to Babbitt and Doland [11] reserve storage for fires should in general be sufficient to meet fire demands plus average domestic demands for 2 hours; in the case of cities, it should be 10 to 12 hours. Fire reserves should be kept ready for immediate use, and not withdrawn during the daily fluctuations of water level in the reservoir.

The volumes of available storage to be provided vary slightly on gravity, and pumping systems. Gravity systems involve a long transmission conduit from the upland impounding reservoir, and the size of this conduit can be reduced if storage for a week or two can be provided in a distribution reservoir. On a direct-indirect pumping system, where the storage ordinarily floats on the line, storage of a few days should suffice. "Equalizing storage capacity is operated through a cycle of withdrawal and replenishment. The theoretical capacity depends on the pumping . . . rates and the rate of consumption. The greatest capacity is rarely more than that required for the demand on the maximum day. A decision as to the actual capacity to be installed rests upon economic studies which determine the combination of storage capacity and pumping requirements that will result in the lowest annual expense." [11] On a direct pumping system (no storage), the capacity of the pumping plant and pipeline must be adequate for the maximum rate of demand: domestic plus fire.

Distribution reservoirs should be located centrally, and as close as possible to the district to be served, and if practicable should be on the side of the distribution system opposite to the source of supply, be it wells, pumping station, or a transmission conduit. They should be placed at sufficient elevation to afford adequate pressures even when emptied to the ¼ stage. If the homes to be served are nearby, the bottom of an elevated storage tank should be at least 30 feet, and preferably more, above the eaves of the nearest house. In locating storage, it must be borne in mind, in general, that ¾ of the pressure can be conserved by feeding a hydrant from two opposite directions.

Distribution reservoirs may be constructed by excavating to form earth embankments on ele-

vated ground, as at Hillview and Silver Lake reservoirs for New York City, or may assume the shape of reinforced concrete-covered, groined, arch structures, like the Provin Mountain reservoir at Springfield, Massachusetts, or the form of reinforced concrete or steel standpipes, or steel tanks on towers. The Jamaica Water Supply Company which supplies 35 mgd. from 52 wells scattered over 40 square miles on Long Island, utilizes for distribution storage 6 steel standpipes, 6 tanks near ground level (5 steel and 1 prestressed concrete) and 10 steel tanks on towers.

The reinforced concrete standpipes built in New England in the beginning of this century, proved leaky and unsightly (Waltham and Attleboro), and present-day labor costs have reduced their economy. Prestressed concrete has lately come into use; while it costs more than a steel standpipe, it can be made more sightly, will be less subject to ice troubles in cold weather, and will eliminate the problem of interior painting, or annual renewal of electrodes for cathodic protection.

Elevated steel tanks on towers appear to be less objectionable aesthetically then steel standpipes, particularly in the recent designs employing elliptical bottoms and tops, and steel tubes in place of H-beams for legs. However, the requirements for spectacular painting imposed by the Civil Aeronautics Commission to safeguard and guide air traffic, has imposed another unattractive feature. Repainting the interior of steel tanks is a major operation, and puts them out of service for weeks. The use of cathodic protection in the last decade has obviated the necessity for painting the interiors and insures uninterrupted use of the tank, but the electrodes have to be renewed annually in freezing climates. The objections of adjacent property owners at Scarsdale to a bare steel standpipe of 1,000,000 gallons capacity necessitated its enclosure in an attractive but costly Martello tower of ashlar masonry, with walls set far enough outside the standpipe to leave space for a spiral steel stairway to the roof.

DISTRIBUTION SYSTEMS

The network of interconnecting pipes extending from the pumping station, wells, or the end of the transmission conduit, to the consumers' premises, or to hydrants is termed the distribution system. The function of a distribution system is to deliver water in required quantities and at satisfactory pressures, under all conditions of demand and operation, and despite a break in any pipe in the system.

While various materials were formerly used for pipes—wood, wrought-iron, cement-lined stovepipe, wrought steel, galvanized steel and cast-iron, the present trend is to cast-iron pipe (cement-lined in regions where the water is aggressive) or asbestos-cement pipe. Some of the larger private companies, notably American Water Works Company, which controls a great many properties, are now installing extensive footages of asbestos-cement pipe. The sizes of pipe, where hydrants are to be served, except in small, limited systems, should never be less than 8 inches. Street mains larger than 48 inches are uneconomical, as they are difficult to procure in cast-iron, property damages due to a break increase as the square of the diameter, and they take up so much room in the street that many existing utilities have to be modified or circumvented by expensive special construction. Seventy-two inch pipes are sometimes used, as in Jersey City and Brooklyn. Only unusual circumstances warrant the use of more than one large pipe in a street, since a break in one will endanger another. Very large cast-iron pipes are subject to shrinkage and other stresses which make them less reliable than steel or reinforced concrete under heavy pressures.

The primary function of hydrants is to afford hose connections for a fire, and they should be spaced close enough together so that no more than 300 feet of hose will be required to play a vigorous stream on a fire. Generally there should be at least one at a 4-way street intersection. Gate valves are essential for segregating a section of pipe in event of a break, and limiting the damaging escape of water. They should be placed on all pipes involved in an intersection, and not more than 1,000 feet apart between intersections. Check valves are required to prevent backflow at pumps. Pressure-regulating valves are required in low parts of the system, to keep the pressure within the limits tolerated by the consumer; excess pressures provoke complaints of air bubbles in the water, and breakage of dishes insecurely held under the open faucet in the kitchen sink. Altitude-controlling valves are spring-operated to close at a prescribed pressure, and prevent overflow of distribution reservoirs and tanks. Cone valves—a recent development—may be operated manually, automatically or electrically, to maintain a constant level in a distribution reservoir, to check backflow when pumps are stopped, to prevent water hammer, or to reduce pressures.

TREATMENT AND CONDITIONING

A large part of this section is taken from *Water Quality and Treatment,* a manual of American Water Works Association, 2d edition, 1950.

Quality of Water.—Waters subject to treatment have qualities broadly characteristic of their sources, as modified by pollutional, chemical and physical agencies to which the waters have been exposed between the point where the skywater hits the earth, and the treatment plant. Natural pollution results from material picked up by the fresh skywater in its travels over or through forest covers of leaves, fertilized crop lands, and pasture lands strewn with manure and other organic debris. Pollution by humans is more injurious, comprising industrial wastes and untreated sewage discharged into water courses; the impairment of quality has been termed roughly proportional to the ratio of population to stream flow. Chemical agencies comprise primarily the soluble minerals with which the water has been in contact, air dust picked up by skywater, and chemical wastes discharged into streams, which agencies increase the hardness and alkalinity of the water, and add carbonic acid, color and odor. In addition streams in flood pick up floating debris and silt (physical impairments), and water in storage is subject to algae, microorganisms, worms and fish (biological agencies). The net effect of these various influences is to add algae, alkalinity, bacteria, color, floating debris, hardness, microorganisms, odors, tastes, toxicity and turbidity in varying intensities to the water delivered for treatment.

There are also counteragents in streams which offset the baneful agencies: sedimentation in still-waters remove some silt and other suspended matter; waterfalls and rifles remove some car-

bon dioxide, tastes and odors; oxidation modifies organic constituents; sunlight bleaches color; and biological agents destroy pathogenic bacteria. These counteragents contribute to self-purification of streams; but time, temperature, and character of the pollution are important factors. Streams of the United States have widely divergent outstanding characteristics; those of the West are likely to be hard, turbid, and low in color; those of New England, soft, clear and colored.

Ground waters, as compared to surface waters, are generally clear, cold, colorless, and harder than the surface waters of the same region. Bacterially, ground waters are generally better than surface waters. Water from limestone formations is apt to be hard and may be polluted through fissures from the surface; it forms deposits on water pipes, and is relatively non-corrosive. In granite formation, ground waters are soft, low in dissolved minerals, relatively high in carbon dioxide, and are actively corrosive. "The temperature of ground water 10 to 50 feet below the surface is usually the mean atmospheric temperature of the locality. Below 50 feet, the temperature increases roughly 1 degree F. for each 60 feet of depth. Ground water temperatures remain fairly constant throughout the year."

Function of Treatment.—It is the function of the treatment to correct impairment of quality so that the water will be fit for human and industrial use, and will not cause formation of tubercles or slime in the pipes. While the primary function of treatment, as advanced by Koch in 1892, is to destroy or eliminate impurities that may cause disease, its function nowadays is considered unfulfilled unless it produces a clear, pleasing potable water, disinfected, and acceptable to both domestic and industrial consumers.

Types of Treatment Available.—Since raw waters differ so markedly in characteristics and the quality desired by the consumer varies with the uses to which it is to be put, the habits of the consumer (Easterners, for instance, suffer from the laxicity of the high sulphate waters which are tolerated by natives of Kansas), and the types of pipes and appurtenances in the waterworks system, different types of treatment have been developed to suit circumstances. The types available include: longtime storage in reservoirs, screening, plain sedimentation, sedimentation following coagulation with chemicals, filtration through slow or rapid filters, disinfection, softening and aeration; also, the occasional use of copper sulphate as an algicide, chemicals for corrosion control, and removal of tastes and odors.

Long-time Storage.—Investigations by Stearns and Drown in Massachusetts in 1890, and Houston in England, later, concluded that long-time storage will reduce color, and nitrates, increase albuminoid ammonia, reduce the number of bacteria of all sorts, including pathogenic, and remove some suspended matter. Many large American cities—New York, Boston, Los Angeles, San Francisco and Vancouver—utilize these benefits of long-time storage as the chief water treatment, supplemented by chlorination. New York applies chlorine after the water leaves the distribution reservoirs at Kensico, Hillview and Silver Lake, where it is exposed to pollution by trespassers and sea-gulls. New York also promotes sedimentation in Kensico reservoir by applying alum to both the Catskill aqueduct and the Delaware aqueduct before their water enters the reservoir.

Screening.—Coarse screens are generally placed in intakes or headworks to divert large floating objects including ice from the conduits. Fine screens which carry mesh of about ¼ inch opening are placed inside the coarse screens to intercept leaves, larva (such as the troublesome bloodworm), aquatic vegetation, and fish. They require frequent removal for cleaning; in many large systems, mechanical cleaning devices are installed.

Plain Sedimentation.—Plain sedimentation (not induced by the application of coagulants) takes place whenever the velocity of flowing water is reduced suddenly; matter carried in suspension is subsided and deposited. It is one of the self-purification processes of streams, and results in the siltation of reservoirs mentioned above. In a water treatment plant, water is held in a quiescent stage in sedimentation basins, for a sufficient interval of time to permit the gravitational deposit of the larger suspended particles. These settle at a rate dependent on their size, weight and shape, and the viscosity of the water. For theory of subsidence, see Hazen, *Transactions of the American Society of Civil Engineers,* vol. 53, p. 45, 1904; also, for later developments, see vol. 102, p. 389, 1937. Modern practice favors upward flow rather than horizontal flow basins, with skimming troughs closely spaced along and across the top to pick up the cleanest water, and with sludge-removal mechanisms installed to remove sludge continually before it has opportunity to mingle with the incoming water. This practice not only insures greater average settling depth (silt builds up to 6 feet on the bottoms of hand-cleaned basins) but insures removal of the sediment without periodically taking the basin out of service, to hose out the mud. At the Little Falls basin of the Passaic Valley Water Commission, silt to a depth of 6 feet has to be removed by hosing, taking the basin out of service at 6 to 8 week intervals. Plain sedimentation at Cincinnati, with 72 hours detention at a 100 mgd. rate, yields 1 foot depth of mud per year on 45 acres; basins are cleaned every 5 years (Ref. 12).

Coagulation.—The process of coagulation consists in adding a coagulant chemical to the water, to bring about an agglomeration of colloidal or finely divided suspended matter into larger masses which will settle more readily in sedimentation basins than the separate particles; this insures removal of greater quantities from the water. The process involves not only the addition of the chemicals to the water but their uniform dispersion through the water by violent mechanical stirring, termed flocculation, resulting in collision of particles and agitation of the water, which builds up a readily settleable floc. Plain sedimentation can be utilized as a sole process, but coagulation requires both sedimentation and filtration, to remove the agglomerated chemicals and impurities. The floc resulting from coagulation enmeshes some organic matter, bacteria, and substances causing color. Coagulation is recommended when the turbidity of the raw water exceeds 30 to 50 parts per million. Some coagulants and water require rapid violent mixing, while others produce better results with slower mixing over longer periods. Flocculators are made by Dorr, Link Belt, Walker and other specialists, and involve some form of rotating

paddle. Sulphate of alumina, commonly called alum, is the most widely used coagulant; it is clean, easy to handle, and effective in its action. Ferric salts have also been extensively used as coagulants; they are nearly as effective as alum, but less convenient to apply. Coagulation periods vary at different American plants, from 3 to 90 minutes, the majority being 10 to 30 minutes; the current trend is to longer periods—30 to 60 minutes, including the time of preliminary flash or rapid mixing. Velocities of 1.0 to 1.3 feet per second are now extensively used for coagulation basin design, and appear to produce about the desired turbulence in baffled basins. It is important that the application of chemicals be uniform, and in proper proportion to the flow of water. Dry-feed machines for chemicals are preferable to wet-feed, effecting closer control of chemicals, economy of space, and elimination of solution tanks and piping.

Filters.—Two types of filters are in successful use in water treatment plants, the rapid-sand (or mechanical) which is widely used, and the slow-sand (or "sand," or "English"), the predecessor to the rapid, and now used chiefly where there are large areas of land available, and where turbidity and color removal are not prime considerations. Slow filters differ from rapid, in many respects: (a) they are available only for gravity flow; (b) they are operated at the slow rates of 3 to 8 million gallons per day per acre; (c) water does not require pretreatment by coagulation and sedimentation; (d) filters must be taken out of service several hours, for cleaning by scraping off the dirty layer of sand, and, upon return to service, filtered water must be wasted for several hours, until the schmutzdecke is reformed on the sand surface; (e) they require 10 times the land, more concrete, but less control equipment. On the other hand, rapid filters (a) can be built for either gravity or pressure flow; (b) can be operated at rates of 125 to 200 million gallons per day per acre; (c) ordinarily require pre-treatment of water by coagulation and sedimentation; (d) can be cleaned quickly by backwashing which requires taking the filter out of service for 10 to 15 minutes. Filters of either type if well designed and effectively operated can be relied on to produce an agreeable water under practically all circumstances. Nowadays filters are not depended on to kill bacteria, which is more certainly done by disinfection with chlorine and other agents, as explained below.

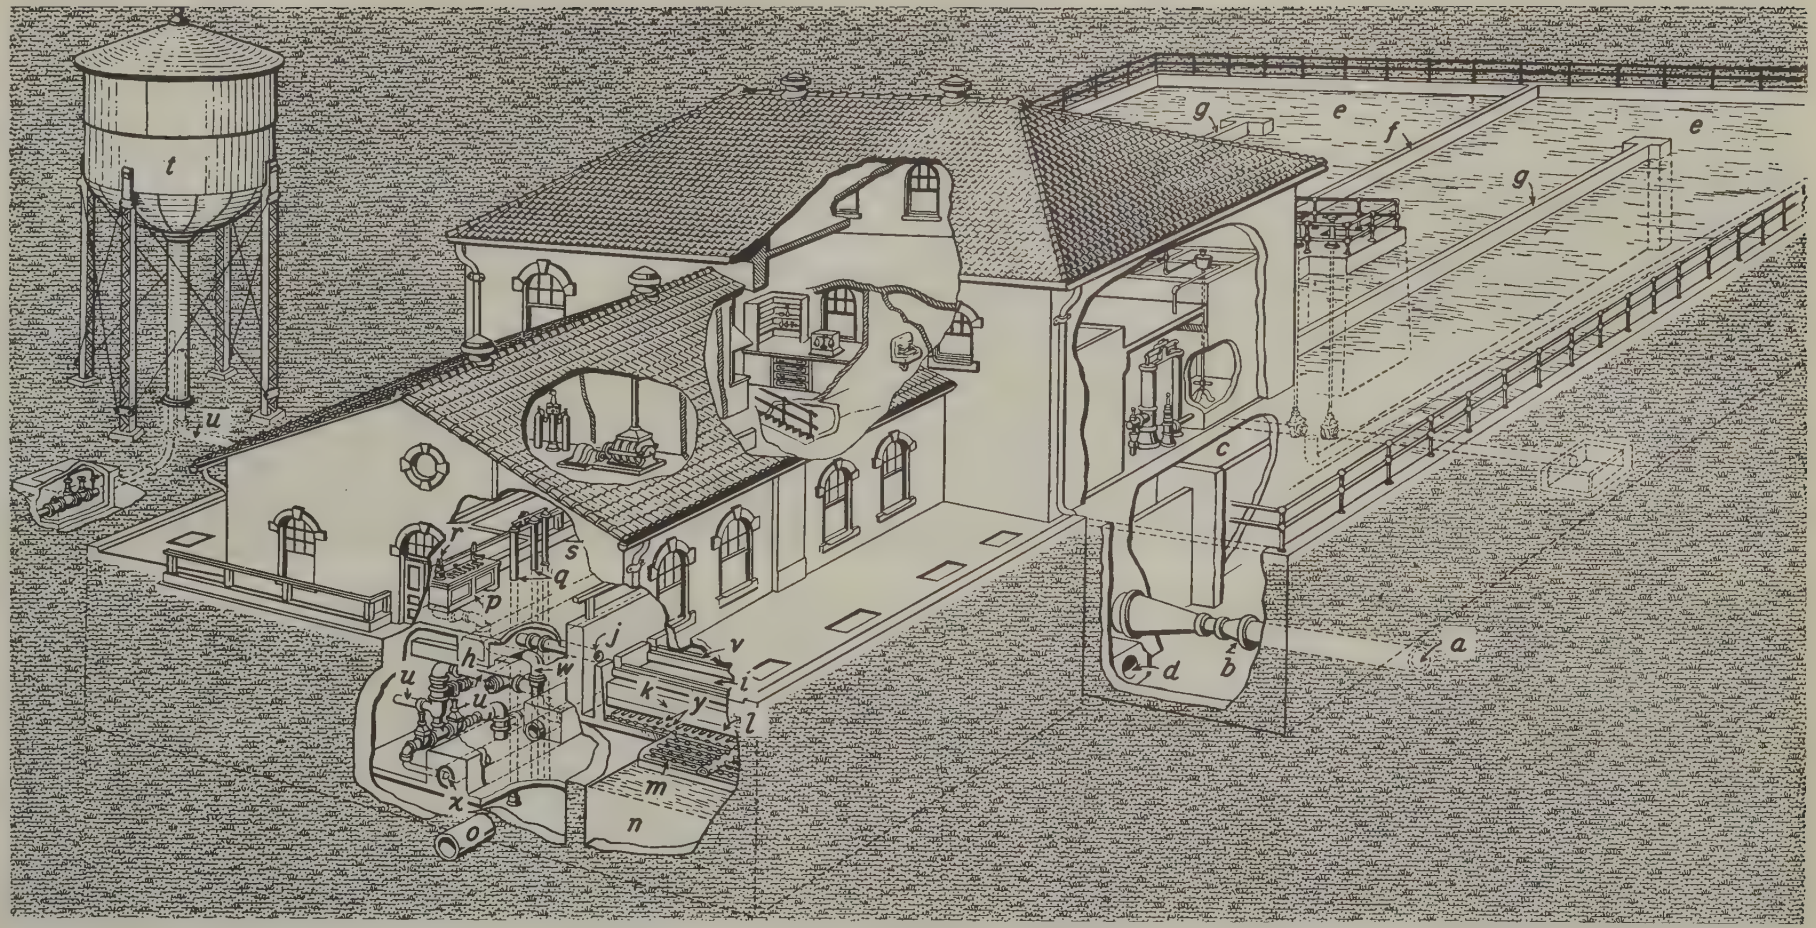
Where turbidity or bacterial loadings are high, or pollution is heavy, rapid filtration has decided advantageous over slow sand; where color and taste removal are important, rapid filters must be supplemented by pretreatment with free residual chlorine, activated carbon, or similar processes. "With adequate pretreatment facilities . . . rapid sand filters are adequate to the treatment of practically all surface water supplies, including those subject to nearly all forms of bacterial and other pollution, high or variable turbidity loadings and excessive algae growths." With modifications, rapid filters are used in connection with water-softening plants.

A filter consists of a bed of sand or prepared crushed anthracite (about 24 to 30 inches thick in rapid filters, and up to 40 inches in slow), supported on a bed of gravel or some other coarse porous material such as carborundum, and contained in a basin, with various operating accessories, for controlling flow, and for washing the basin. The American Water Works Association (1948) issued specifications for filtering material, which are accepted as standard.

Steel explains the clarifying effect of sand filters (more effective than strainers) as follows;[12] The minute void spaces between the sand particles act as small sedimentation chambers and thus permit the suspended particles to come in contact with the surfaces of the sand particles, which surfaces soon become sticky, from residues of coagulants carried onto the filter, and from slimes. The suspended particles in their tortuous downward path through the filtering medium touch these sticky surfaces and adhere. This soon results in an accumulation of removed suspended matter in the top few inches of the sand which forms a dense blanket of mud, floc, and living or dead organisms; this accumulation is termed the schmutzdecke. It was formerly held that the schmutzdecke was highly important in filtration, but it is now known that relatively clean sand, with only a thin film upon the sand grains, is as effective as a bed with a dense blanket at the surface. There is also the possibility that the sand particles have an electrical charge opposite to the ions in the colloids. The sand particles will therefore attract colloidal matter until the electrical charges are neutralized. As the bed is washed, the accumulated material will be removed, and the electrical charge of the sand restored.

Layouts of rapid sand filter plants vary with local conditions, the experience of the designer, and the size of the plant, but in general, follow the scheme shown in Fig. 1. The water enters through pipe *a* (lower right hand corner) and through the Venturi meter *b* into mixing chamber *c* where the coagulant is applied. (The flocculator is not shown.) The coagulated water then passes to sedimentation basins *e* through conduit *d;* here the floc settles out. The two basins are separated by wall *f* so that they may be operated separately. (In some plants, sludge removing equipment would be installed here.) Wall *g* provides a baffle to guide the water in even flow, and prevent cross currents and short-circuiting. (Valves, in the bottom of the basins, for clean-out of sediment, are not shown.) The flume *h* leads the water from the sedimentation basin to the various filter boxes *i*, through the influent pipe *j*. The water percolates down through the sand *k*, which is supported on gravel *l*, which in turn is supported on the filter bottom *m*. It flows into the clear-water reservoir *n* beneath the filters. The filtering and washing operations are controlled from the operating table *p*, the rate-regulator *q*, and the loss-of-head gage *r*, which are located on the operating floors over the operating gallery. Filtered water for back-washing the filters is stored in the elevated wash-water tank, *t*, from which it is fed through pipes *u* into the filter bottom *m*, and flows upward at high velocity through the gravel and the sand, causing the sand to float to a limited extent, so that it is more easily freed of dirt. The wash water and dirt are carried into the gutters *v*, and thence into the drains *w* and *x*.

The filter boxes range in capacity from 0.3 to 2.0 million gallons per day, and are generally arranged symmetrically about either side of the operating gallery which is the enclosure under the operating floor, provided for the pipes and valves. In northern climates, the entire filter is enclosed, but in the deep south, only the operat-

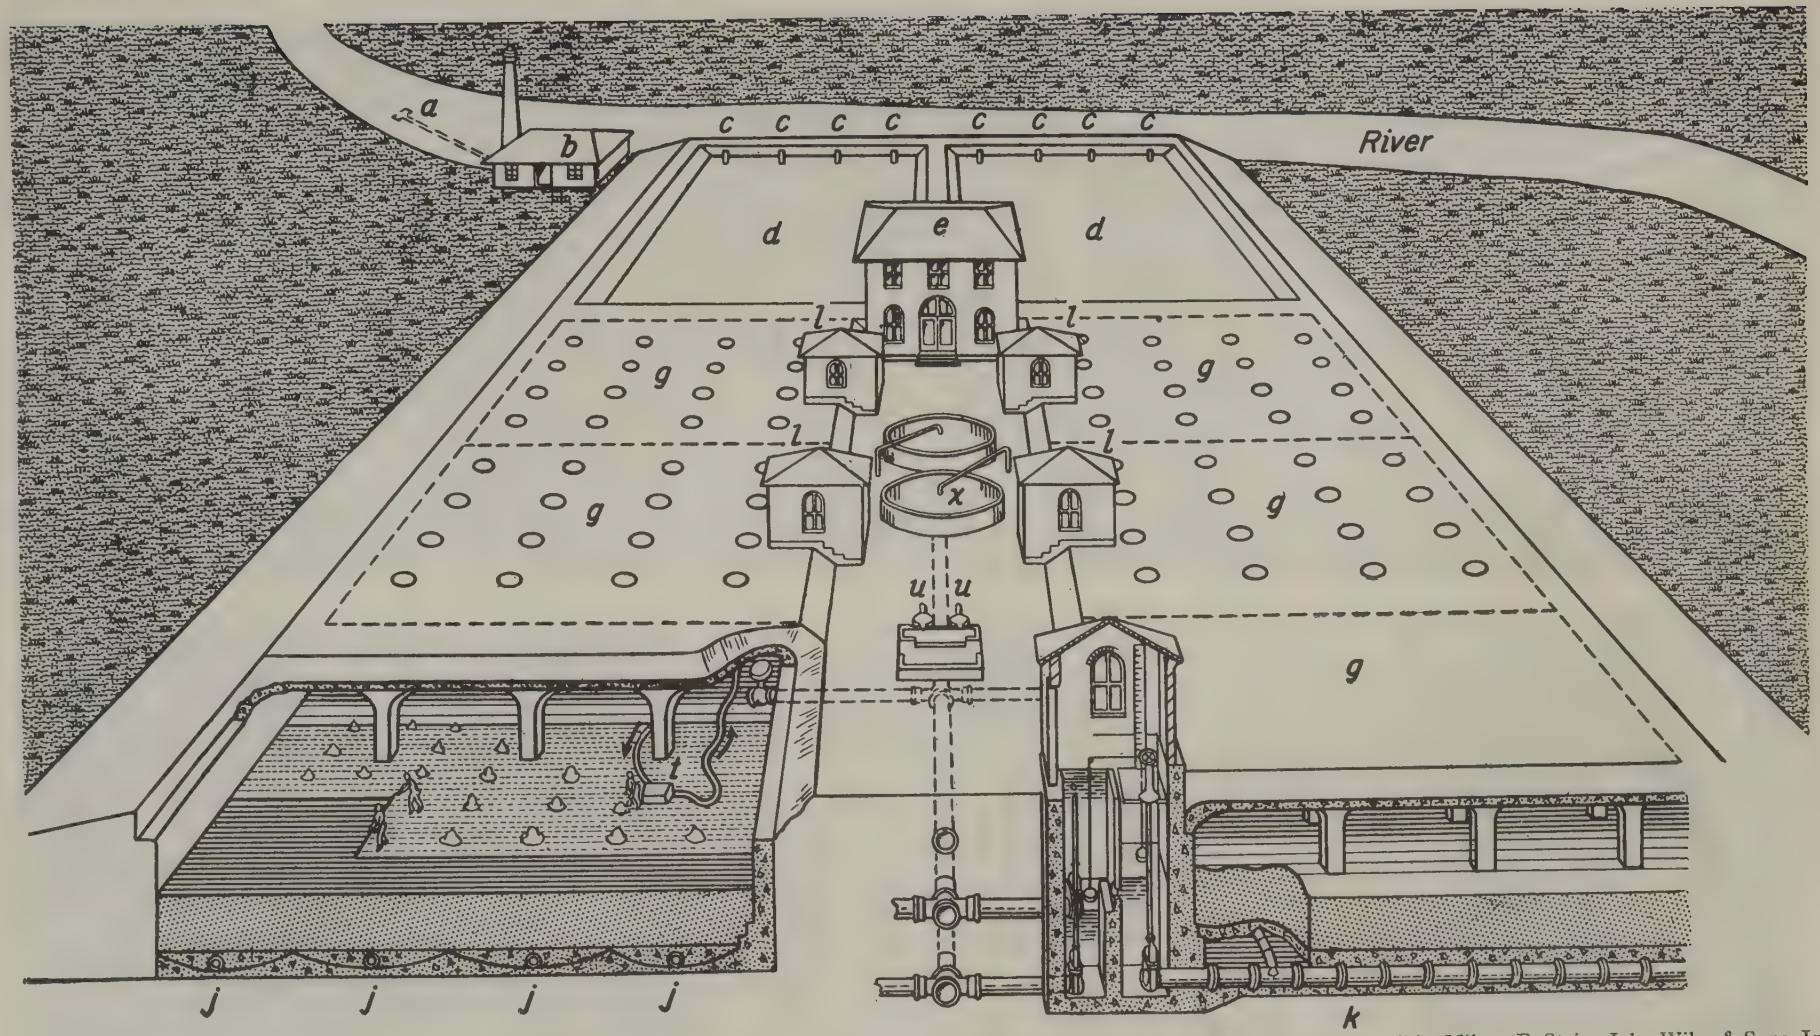


Redrawn by permission from *Water Supply and Purification* by William A. Hardenbergh; International Textbook Company, 1945.

FIG. 1. Typical arrangement of rapid, or mechanical, filter plant.

The raw water passes from the main *a* through the Venturi meter *b* into the chemical chambers *c*, where the coagulant is mixed with it. From the mixing chambers the coagulated water flows through the flume *d* to one of the sedimentation basins *e* (at the far end in the illustration), in which the precipitate is allowed to settle. There are two similar basins, one being in use while the other is being cleaned or is held in reserve. The two basins are separated by the wall *f*, and each basin has a baffle wall *g* to guide the water and prevent cross-currents. After passing through one of the sedimentation basins, the water enters the flume *h* (shown at the near end *in* the illustration) and is distributed to the various filter units *i* by pipes *j*. The water percolates down through the sand *k* and the gravel *l*, is collected by the strainer bottom *m*, and is carried to the filtered-water reservoir *n* under the filters. From the filtered-water reservoir, the water passes out through the pipe *o* to the elevated tank or reservoir from which the water supply is to be taken.

The filter is operated and regulated by means of the valve controls *p*, the rate-regulating apparatus *q*, and the loss-of-head gauge *r*, that are located in the gallery or operating floor *s*. Filtered water to be used for washing the filters is stored in the tank *t*, from which it is led through the piping *u* to the filter bottom *m*, and is forced upwards through the gravel and sand. The wash water, carrying the dirt and sediment in the sand, is discharged through the troughs *v* and the sewer *w* into the waste *x*. Air for agitating the sand during cleaning is supplied through the piping *y*.



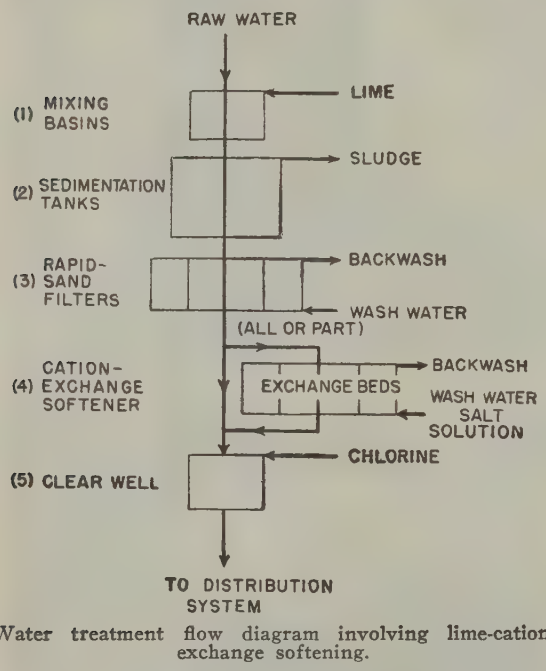
Based on "Water Purification Plants and Their Operation," by Milton F. Stein; John Wiley & Sons, Inc.

FIG. 2. General view of slow filter plant.

This consists of duplicate sedimentation basins, *d*, the filter units, *g*, the laboratory, *e*, etc. Low-lift pumps, *b*, take water from intake, *a*, and deliver through aerating risers, *c*, to sedimentation basins, *d*. Water is uniformly distributed to filters, *g*, by a float valve. Collector pipes, *j*, collect the filtered water and lead to the main collector, *k*, which leads to the regulator house, *l*, whence it flows through regulating orifices to the clear water well. A portable sand ejector, *t*, is employed when the sand requires washing. Sand washers, *u*, discharge the clean sand to sand storage bins, *x*.

ing floor is roofed over. The filtered water basin is generally situated beneath the filter boxes, and provides support for them, and short piping from the filter boxes.

Disinfection and Chlorination.—Disinfection is the process of killing a large proportion of microorganisms, by means of chemicals, heat, ozone, ultraviolet rays, etc. Liquid chlorine was first employed in 1909, and was commonly added to raw or coagulated water just prior to filtration. Currently, the value of chlorination for disinfection, and hastening other chemical or biological results and in producing a satisfactory effluent, is recognized. It is applied both before and after filtration. Chlorination materially improves the coagulation of some waters. Prechlorination may also control the growths of algae, reduce biological accumulations in filters, and contribute to improved filter efficiency, and lengthened filter runs. Postchlorination appreciably reduces the number of bacteria of all types entering the distribution system. When ammonia is combined with chlorine, a slower acting disinfectant results, which has been found beneficial in retarding growths in long pipelines leading to the distribution system, and for suppressing the development of iron-fixing or slime-forming types of bacterial growths. "The wider adoption of treatment utilizing greater chlorine additions may be expected in the future, inasmuch as high-rate chlorination provides a means of achieving a high standard of bacterial quality and of improving plant practice, including the elimination of certain types of tastes and odors." [13]



Water treatment flow diagram involving lime-cation-exchange softening.

Chlorination, however, is not a substitute for more general treatment. Preliminary coagulation and sedimentation plus filtration are generally required for removing color, turbidity, and obnoxious industrial wastes, but chlorination may lead to a more satisfactory effluent when combined with these processes.

Chlorine is a greenish-yellow gas which under pressure is converted to a liquid. Commercially, it is available in steel cylinders, of various capacities, ranging from 100 to 2,000 pounds. At 70°F., the pressure required to maintain the liquid form is about 85 pounds per square inch, but the pressure increases as the temperature rises. When the liquid is drawn from the cylinder, the release of pressure causes it to change back to a gas. Chlorine, to be effective, must be applied continuously, and in definite proportions to the water flow. Liquid chlorine is fed from the pressure cylinders, to the water through a machine termed a chlorinator, which automatically proportions the gas to the rate of flow.

The mechanism of the action of chlorine in destroying bacteria and microorganisms has been the subject of much conjecture. Formerly, it was held that chlorine reacted directly with water to generate nascent oxygen, which had a definite bactericidal action on the cell. This theory was disproved; the general belief nowadays being that there is a physicochemical reaction between chlorine and the proteins and amino groups in the cell wall and contents, causing disintegration of the cell and destroying its life. Green and Stumpf [14] have suggested another explanation based on inhibition of a key enzymatic process, which oxidizes the glucose of the cell. Chlorine destroys this power of oxidation, so that the bacterial cells die.

The most recent development in the use of chlorine has been the breakpoint method, whereby more effective bactericidal action can be obtained, and tastes and odors removed, with a minimum quantity of chlorine.

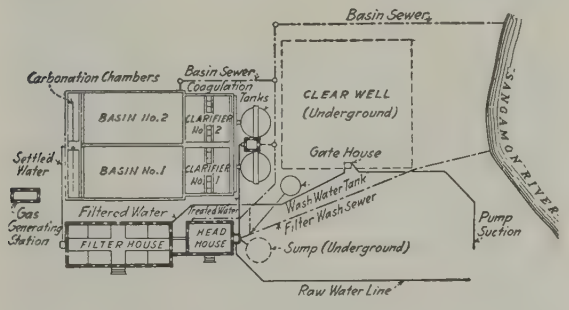
Chlorine dioxide—a compound of chlorine and sodium chlorite—possesses greater chemical activity than chlorine alone, and produces a more rapid oxidation of some organic compounds. It was first introduced in water treatment about 1940, for destruction of taste-producing substances which frequently result from chlorination. It destroys chlorophenols, and similar taste-producing compounds; in some instances, it has reportedly proved effective in precipitating iron and manganese.

Ozonization is employed at the Belmont filters at Philadelphia for taste and odor control. Ozone is a faintly blue gas of pungent odor; it is oxygen in molecular form, three atoms of oxygen comprising a molecule; it is an unstable allotrope, and readily breaks down to normal oxygen and nascent oxygen, which is a powerful oxidizing agent. Ozone is produced by the discharge of high voltage electricity through dry air in a closed apparatus known as an ozonator, and is applied to water by discharging into a scrubber or into an injector, or by spraying the water into ozonized air. At Ashton, England, ozonization is reported to disinfect, and reduce color, tastes, and odors.

Ultraviolet rays are employed for swimming pools, but have been found too expensive for any but small municipal installations. The water to be disinfected is made to flow in a thin film past a series of quartz mercury-vapor arc lights emitting ultraviolet light. Turbid waters must be filtered, and color reduced to 15 parts per million (ppm.) before the rays are effective.

Softening.—The hardness which is added to skywater due to minerals dissolved by running over the surface, or percolating underground, is a real expense to the consumer unless reduced by softening. Steel [12] claims "Water softening has so many advantages that there is little excuse for the fact that it is not more widely used. . . . Hard water is a continual though unrecognized expense to water users. For a family of five, Applebaum estimated in 1932 that moderately hard water will

cause a 'hard-water tax' of $44 per year, divided among the following items: soap destroyed, plumbing bills due to scale in pipes, extra fuel caused by scale in hot-water and steam heaters, decreased life of fabrics washed in hard water, and increased wear on cooking utensils." In 1936 it was estimated by Charles P. Hoover that the cost of soap due to hard water amounted to approximately $1.00 per capita per year for each 100 parts per million hardness. Data cited by Turneaure and Russell[7] for 1,034 groundwater supplies in the midwestern states show only 63 with hardness below 100 ppm., 835 above 200, and 537 above 300. According to Howson[15] softened water is now served to approximately 15,000,000 people in the United States. At present prices, large softening plants (about 80 mgd. capacity) can be built for about $55,000 per mgd. capacity; in capacities from 15 to 18 mgd., for about $90,000 per mgd., and a 2 mgd. plant for about $125,000 per mgd. The annual cost of removing 200 ppm. hardness from average water, by the lime-soda process, would be 6.2 cents per 1,000 gallons for a 6 mgd. plant, and 4.1 cents for an 80 mgd. plant, including fixed charges, chemicals and labor. He estimates that 50 per cent of the consumers, who use 3,000 gallons of water per month, at a minimum charge of $1.50, would be assessed an additional 25 cents per month for softened water, which would be offset by the saving on soap, fuel and plumbing. He concludes: "Softening can be accomplished more economically and satisfactorily in public works than by individual household softeners."



Typical municipal softening plant—(Springfield, Illinois).

Water softening processes for municipal plants are either the cold lime-soda process, the cation-exchange process (formerly called the zeolite process), or a combination of the two. In the cold lime-soda process, the steps are usually: addition of chemicals (generally lime and soda ash), mixing, sedimentation in basins for the reaction to take place, rapid sand filtration, and recarbonation to prevent the formation of incrustants and scale. If the water were not recarbonated (by diffusing carbon dioxide gas through it, to restore the carbon dioxide removed by the reaction with lime) the water would be unstable as to the solubility of carbonates and the corrosion of metals. The lime-soda process involves the handling of dusty lime, the disposal of great quantities of sludge, and expert supervision of recarbonation; if the recarbonation is not properly done, the sand, gravel and equipment in the filters, and the pipes in the distribution system, will accumulate coatings of carbonates of calcium and magnesium.

The cation-exchange softener is the most widely used type in municipalities, industries, and homes. In industries and homes, a water of zero hardness is produced, while in municipalities, completely-softened water is mixed with hard water, to produce a water of tolerable hardness. The softener occupies comparatively little space, and is simple to operate. A cation-exchange water softener consists essentially of a container (gravity or pressure type) for the bed of exchange material, and piping and appurtenances for passing water through that material in one direction for softening the water, and in the reverse direction for the regeneration of the bed. In the reverse flow, the water carries brine. There is also required a storage bin for the salt, and a tank for saturated salt brine. The principle of this process lies in the ability of certain sodium compounds, which are insoluble, to exchange cations with other substances in the water; when a hard water is passed through a sodium cation exchanger, the calcium and magnesium in the hard water are replaced by sodium from the exchanger. Since the action is reversible, the "exhausted" cation exchanger can be "regenerated," with a solution of common salt, once all the readily replaceable sodium has been exchanged for calcium and magnesium from the hard water. In the regeneration, the calcium and magnesium of the exhausted cation exchangers are replaced with a fresh supply of sodium from the regenerating brine unit. Then, after washing with water to free it of brine, the exchange material in the filter is in condition to soften a fresh supply of hard water.

Corrosion may be an incidental result of cation-exchange softening, unless provision is made to guard against it. Water softened by this process is not in itself corrosive, but the absence of magnesium and calcium compounds prevents the formation of a coating based on alkaline hard water which protects the metal from attack by oxygen, the real corrosive agent. To protect pipelines in distribution systems, it is therefore advisable to mix the softened water with the raw, or make such adjustments to the pH and alkalinity, as will produce substantial saturation with calcium carbonate.

Aeration.—Aeration is the process of bringing about the intimate contact of air and water by any of the following methods: spraying the water in the air, bubbling air through the water, or by agitation of the water by cascades, etc., to promote surface absorption of air. Aeration removes hydrogen sulphide, simple chlorine odors, and odors caused by decomposing organic matter; it can greatly reduce odors caused by microorganisms, and can remove some iron and manganese. Odors caused by chlorine combinations are only slightly affected. The aeration methods employed depend on the efficiency desired, and on the hydraulic head available. Jet aerators, such as are used at Ashokan and Kensico reservoirs on the Catskill water system of New York City, are most efficient, but require loss of 10 to 20 pounds pressure. At 10 pounds a properly designed nozzle with a 1-inch orifice, will discharge 72 gallons per minute, to a height of 7 feet. Cascades, which are much used in industries, comprise 3 or 4 open metal steps, or concrete steps, down which the water tumbles, impinging on each step. A series of slag-filled trays built vertically over each other, with screened or slatted bottoms, providing a fall of 18 inches from tray to tray, using about 5-foot head for 4 trays are termed tray aerators or trickling beds. They are more efficient than cas-

cades, particularly for removing musty tastes and odors imparted by algae, but are less effective than jet aerators. Compressed air can also be blown into the water mechanically through porous plates so set as to induce spiral flow. The patented Aeromix operates in a draft tube through which air at atmospheric pressure is sucked.

Tastes and Odors.—Tastes in water and the odors that are closely associated with them are caused by (a) dissolved gases, such as hydrogen sulphide, (b) organic matter originating in algae and other microorganisms, either living or in process of decay, (c) decomposing organic matter in general, (d) industrial wastes of which phenol is the most troublesome, (e) chlorine, either as a residual, or in combination with phenol or decomposing organic matter. Most tastes, except those caused by chlorine alone, can be removed by an oxidizing agent. One such agent—widely used—in over 1,200 American treatment plants—is activated carbon, which had its first application in 1930 at the New Milford treatment plant of the Hackensack Water Company. Its wide-scale adoption in 20 years amply testifies to its efficacy and economy, based on ease and flexibility of application and low cost. Activated carbon is produced by charring wood or a similar inexpensive material, and then subjecting the char to an activation process. The resultant carbon surface has a property, termed "adsorption," to attract and hold odorous substances present in the water.

As mentioned above, chlorine is most valuable for taste and odor control. It is a strong oxidizing agent which when present in water as free available chlorine, will convert many of the odorous compounds to oxidized, less objectionable forms.

Corrosion Control.—By the addition of lime or soda, to water containing free CO_2, in such quantities that unprotected metal pipes will be corroded and tuberculated, water can be maintained in such chemical balance that the pipe coating is not dissolved, and the metal is protected from corrosion. "Carbon dioxide tends to dissolve carbonates, and water containing enough free carbon dioxide to dissolve a coating of carbonates that has been previously deposited is said to be aggressively corrosive." [8] Of recent years, sodium hexametaphosphate (sold under the trade name of Calgon and Nalco-18) has come into increasing use, to combat corrosion and tuberculation in metal pipes. "Conflicting results have been reported. Recent disclosures cast doubt whether corrosion of mains is prevented by this treatment. It seems to be well established, however, that these metaphosphates secure the following results: (1) precipitation of iron already in the water or that due to corrosive action is prevented; (2) large tubercles are not formed in the mains, so that the pipe surface remains smoother than would otherwise be the case; and (3) the products of the corrosion of the small water piping in buildings do not collect and clog the piping." [13]

CONSERVATION

In *The Saturday Evening Post,* May 13, 1950, Hugh H. Bennett of the United States Conservation Service warns that cities and areas plagued by water shortages grow in number each year. In February 1950, the United States Geological Survey reported "some 50 areas where the supply of suitable water for household, industrial or agricultural use could become serious or already is critical . . . with adequate hydrological investigations . . . shortages in most communities can be met intelligently, or avoided, by making an approximate analysis of the quantity and quality of the water needed, and by designing the systems on the basis of reliable information on the sources of water to be developed. . . . The Geological Survey methods and technique for determining the dependable yield of present or prospective sources of water are available, and where carefully carried out, can afford confidence to a community and its industry that it has an adequate source of water on which to base its future." (*Engineering News Record,* Feb. 16, 1950.)

There is ample water, if properly conserved and developed. Carhart [16] declares that the runoff from annual rainfall, evenly spread over the United States, would yield 8.7 inches, whereas national demand for domestic, industrial and agricultural purposes, and irrigation, could be met by 1 to 1.5 inches of this available average supply. Although water supplies are not inexhaustible, the average citizen feels little compunction not to waste water; his interest in water resources ends at the bathroom tap. Recent restrictions imposed in New York City, and elsewhere, confronted the ordinary citizen with the exhaustible phase of his water supply, and the necessity to conserve dwindling supplies.

The conservation of ground water resources is particularly important, since heavy pumping near the seacoast lowers the water table to such an extent that sea water will flow landward, requiring the well to be abandoned. This has happened to the New York City wells on Long Island, to the deep wells at Atlantic City, and to wells in the Los Angeles district (Long Beach and along the coast from Santa Monica to Santa Ana, and the southwest Basin), in the Panhandle region of Texas, Savannah, and Brunswick, Ga.

Supplementing deficient supplies of fresh water by using desalted sea water has been considered by large seaside municipalities such as New York and Los Angeles, in view of the successful use of desalting equipment to supply thousands of persons on South Pacific Islands during World War II. Studies by the Metropolitan Water District of Southern California are presented by W. W. Aultman, Water Purification Engineer of the District, in the *Journal* of the American Water Works Association, 1950, p. 791, wherein he shows that treatment alone, by the cheapest method—vapor-compression distillation—will cost $1.25 per 1,000 gallons, excluding distribution costs, as compared to usual rates, including distribution charges, of 10 to 15 cents. Aside from the essential problem of costs, "from an engineering standpoint, there is no question that fresh water can be and is being produced from sea water. But within the foreseeable future, and in the light of current technological knowledge, there appears to be no possibility that it will be economically feasible to turn to the ocean as a source of domestic, industrial or agricultural water along either coast of the United States."

Powell and Bacon [17] recommended in 1950 to the American Water Works Association a local and regional survey of actual and potential surface and ground water resources, and an inventory of water requirement on a national basis; discouragement of overindustrialization on the critical watersheds; decentralization of large industries using great quantities of water; control of flood waters to avoid runoff of water needed

for supply; encouragement of use of desalted or salt water, to conserve water; expansion of the activities of the state and federal agencies controlling critical underground resources; coordination of activities of authorities controlling waste regulation and those concerned with the allocation and utilization of water resources.

A temporary Water Resources Commission was appointed by President Truman, January 1950, when the domestic water supply shortage became critical in several widespread areas of the country. It was directed "to make a prompt survey of the water-supply situation in this country, and report its recommendations to Congress for legislative action." The commission brought out 70 items in its "Outline of Policy," three dealing directly with those phases of water supply with which the present article is concerned. Briefly, the committee recommended that: (1) municipal works and metropolitan water districts should continue to be administered locally rather than federally, but coordinated into comprehensive basin (the drainage area of a major stream) programs; (2) utilization by water works of the storage facilities incidental to a multiple service reservoir system, should carry a financial charge; (3) basin program should consider the water supply needs of industries, particularly those utilizing the oil shales. Recharging of ground water reservoirs should be considered in basin programs, together with the economic possibilities of so storing excess flood waters (see discussion by Morris [18] of the Water Resources Commission).

CLINTON L. BOGERT,
Consulting Engineer; Coauthor of "Waterworks Handbook."

WATER TABLE, *in architecture,* a projecting stone sloped on the roof to throw off water. It occurs in buttresses and other parts of Gothic architecture. In *hydraulic engineering,* the upper limit of the portion of the ground which is wholly saturated with water. In agricultural districts a lowering of the water table by reducing the supply of well water creates serious economic problems for the residents.

WATER THRUSH. Any of several species of North American warblers, genus *Sierus,* usually found near streams. The species include the ovenbird (*S. aurocapillus*) which breeds from northern Ontario to northern Georgia; the northern water thrush or water wagtail (*S. noveboracensis noveboracensis*); Grinnell's water thrush (*S. noveboracensis notabilis*); and the Louisiana or southern water thrush (*S. motacilla*). The plumage is olivaceous above and streaked below. See also OUZEL.

WATER TURBINE. See TURBINE; WATER WHEEL.

WATER VALLEY, city, Miss., and one of Yalobusha County seats; altitude 294 feet; 119 miles northeast of Jackson, the state capital; and 13 miles north of Coffeeville, the other county seat; on the Illinois Central Railroad. It was settled in 1855 by William Carr; incorporated in 1858, and chartered as a city in 1890. It was occupied by Federal troops during the Civil War. In 1873 it was made a county seat and that same year suffered from an epidemic of yellow fever. Its industrial prosperity long centered about the Illinois Central railroad shops. These were moved to Paducah, Ky. in 1929. It is an agricultural region, in which cotton is one of the principal products. A major activity is the growing and shipping of watermelons. The chief manufacturing establishments are a garment factory, axe handle factories, and a stave mill. The city owns and operates the local waterworks and obtains electric current from T.V.A. The government is vested in a mayor and board of aldermen. Pop. (1940) 3,340; (1950) 3,217.

WATER WHEEL, a machine by which the energy in falling water is utilized to perform mechanical work. Water, through its tendency to seek the lowest level—the point nearest to the center of the earth—acts as a motive power by its weight. When the water is confined, as in a vertical pipe, this weight becomes pressure. When the water has acquired a velocity in flow its motive power is called impulse. Water wheels adapted to these various conditions may be divided into two general classes—the "vertical," consisting of the "overshot," "breast" and "undershot" wheels; and the "horizontal," which includes a great variety of turbine or reaction wheels. The impact or impulse wheels are represented in both classes. The term water wheel is correctly applicable to all forms of water motors that rotate, but in this article it will be restricted to those of the vertical class. For those belonging to the horizontal class, see TURBINE.

The overshot wheel is so called because the actuating water is fed to it from the top. It is provided with a number of buckets fixed to its periphery in such a way that as the wheel revolves the buckets on the descending side have their tops upward, and being filled with water at or near the top of the wheel, the weight of the water exerts a downward pull and the axle of the wheel being free to turn in its bearings, a rotary motion is imparted to the axle from

which it is transmitted by belts or gearing to the mechanism to be operated. The water is admitted to the wheel by various methods, such as the overfall sluice, the penstock and the guide bucket, in all of which the water is guided in a course tangential to the perimeter of the wheel. If the water is in motion, that is, has a certain velocity, when it enters the wheel buckets, it acts partly by impact, but in usual conditions the motive power of the wheel is simply the weight of water in its descending buckets, which may be roughly estimated as the cubic content in feet of two-thirds of the number of buckets, multiplied by 62½ pounds. To obtain the greatest efficiency, the number of buckets, ought to be as large as possible and so arranged as to hold the water as long as practicable. The buckets vary in form, but the greatest effect is obtained from curved buckets, the «radial» giving only about 75 per cent of the power obtainable by the use of «elbow» buckets. Overshot wheels may be constructed of wood or iron in any size. The earlier forms were massive structures built of wood; the modern wheels are generally built of iron and are practically limited by construction problems to falls less than 60 feet in height. The average sizes range from 8 to 40 feet in diameter.

In the breast wheel the water is received by the buckets on a level with or but slightly above the axle of the wheel. It is most effectively employed in connection with falls ranging from 5 to 20 feet, and where the flow ranges from 5 to 90 cubic feet per second. The buckets are generally held in a curb, and, not being required to hold water, are set radially. Their number is made as large as possible, and they are set at such an angle that they leave the water vertically so as not to carry up water from the tailrace. The breast wheel is more effective than the overshot where the fall is low, since it can be made of nearly double the diameter and affords an increased facility for the reception and discharge of the water by the buckets, besides gaining some power from impulse.

The undershot wheel receives the water below its horizontal centre line. Instead of buckets it is equipped with a series of paddles or vanes fixed to the periphery in such a way that the flowing water passing under the wheel pushes against the paddles, causing rotation. It is usually set in a curb with a minimum amount of clearance for the escape of the water. The most effective curbs are concentric to the wheel, those set straight or tangential allowing too much waste. The paddles are set radially and inclined upward in order to be readily emptied of water upon the return side.

For falls not exceeding six feet, the most effective wheel is the Poncelet. In it the water acts in a manner very similar to its action in a turbine, and although not quite as efficient as turbines working under normal conditions, it is superior when working under a reduced water supply. The buckets are curved, and the water flowing along their concave sides presses upon them without impact and with greater effect than that of water impinging at right angles against buckets with plane surfaces. The effect of the wheels increases with the depth of the water, and the velocity of rotation is equal to about one-half the velocity of the flowing water. The simplest form of the «impact» wheel consists of a series of rectangular buckets fixed upon a wheel at an angle varying from 50 to 70 degrees to the horizontal. The water is conducted to it through a pyramidal flume set at an angle varying from 20 to 40 degrees, so that it strikes the blades nearly at right angles. The normal effect is about 5 per cent of the total mechanical power of the flow, but this may be increased somewhat by increasing the length of the paddles, so that the water exerts a combined impinging and pressing force.

In another form, known as the «impulse» wheel, a series of cup-shaped buckets attached to the periphery of the wheel are acted upon by a jet of water conducted by a pipe and delivered through a nozzle tangentially against the cups. More power is obtained by increasing the number of nozzles to two, or even four. Of this form the most notable are those of the Pelton type, which are extensively employed to work air compressors in mining operations. At first limited in usefulness to the locality of the power, the development of electric power transmission brought them into a greatly enlarged field of service. Such wheels are now operating under heads up to nearly 2,000 feet. A Pelton wheel in the service of the Southern California Edison Company, working under 1,900 feet head at 430 revolutions per minute, develops 1,600 horse power. This wheel has been running continuously since 17 March 1903. At a plant recently erected in Europe, a jet of water one and one-half inches in diameter under a head of 5,250 feet develops 3,000 horse power. The Rio Janeiro Traction, Light and Power Company operates a Pelton wheel with four nozzles under 900 feet of head. The power developed is equivalent to 20 000 horse power.

The efficiency of the turbine being so much greater than that of any type of vertical water wheel they are universally preferred except in the smallest water power developments. This statement, however, does not apply to the Pelton wheel whose efficiency is equal to the turbine, and is available where the head is too great for economical use in turbines. The largest vertical water wheel ever built in America was the Burden wheel, located on the bank of Wynant's Kill, which enters the Hudson River near Troy, N. Y. This wheel was of tension construction, the 264 spokes being one and one-half inch rods bolted to rosettes on the 12 inch shaft. Its diameter was 60 feet, and its face width was 20 feet. The water was brought to the wheel through a steel penstock which crossed the wheel transversely at its summit. Four gates at intervals in this penstock were in the constant charge of the wheelman who opened or closed them so as to keep the supply such that it would turn the wheel at a constant speed of two and one-half revolutions per minute. On the outer sides of the rim were circular cogged racks which engaged with pinions seven feet in diameter and nine inches face keyed to the shaft, which projected 31 feet into the mill. This wheel was in constant operation 45 years, much of the time running night and day for long periods. It was abandoned in 1898 as of insufficient power for the needs of the business, but remained intact for 15 years thereafter before it began to fall into decay. The largest water wheel in the world is that which supplies the ancient city of Hama with water for drinking and irrigation from the river Orontes —

about 120 miles north of Damascus. This wheel is of the undershot type, 70 feet in diameter and of comparatively narrow face. It is built of wood upon an iron axle.

Bibliography.—Good descriptions of water wheels are scattered through the various engineering periodicals. Especially valuable data may be obtained from *Transactions of the International Engineering Congress* (1916); Le Conte, J. N., *Hydraulics* (New York 1937).

WATER WILLOW, common name of a number of species of herbs, as the American herb *Dianthera americana;* the purple loosestrife; the great willow herb; the swamp loosestrife; and the Eurasian willow, *Salix aquatica.* The water willow has long narrow leaves, it bears purplish flowers, small, in spikes. The willow herb, *Chamaenerion angustifolium,* grows in most parts of the north temperate zone; it is known also as fireweed and French willow.

WATER WORSHIP, a feature of nature worship, and one of the primitive superstitions of mankind. Water was not worshipped as an element, but in its various forms of well and spring, river and ocean. Every spring and river was supposed to have an animating deity, who could be propitiated or offended, and the worship of these divinities was a prominent part of Greek and Roman cult, especially in the rural districts. An excellent example of water worship, with a slightly different aspect from that of the Greek and Roman world, is the Hindu faith in the virtuous powers of the Ganges River. Particularly at the point where the Jumna flows into it, the Ganges is supposed to have power to heal and cleanse. Native belief is that the stream flows from the feet of Brahma, and it is this divine origin that endows the waters with curative powers. (See GANGES.)

WATERAGE, transportation of goods by water; also, the charge for such carriage of goods. In commercial use the word is similar, in construction and in manner of application, to *freightage, haulage, truckage.*

WATERBAILAGE, a duty assessed against goods upon delivery after being conveyed by water; in England formerly a customs charge levied by the city of London on goods shipped by water into or out of the city.

WATERBERG, geological designation of a formation of rock in South Africa. It applies to the uppermost stratum of sedimentary rock of the Paleozoic period preceding the Devonian. Sandstone, shale, and conglomerates are its principal components; some lavas are associated with it. The name is from Waterberg, South Africa.

WATERBORO, town, Maine, in York County, 21 miles west of Saco, on the Sanford and Eastern Railroad. The town is situated at an altitude of 285 feet and includes several small villages. Nearby are Little Ossipee Lake and Ossipee Mountain, 1,050 feet high, affording facilities for camping in summer and skiing in winter. Waterboro was settled in 1760 and incorporated in 1787. Pop. (1950) 1,071.

WATERBUCK, an African antelope of the genus *Kobus.* There are two species to which the name is applied, *K. ellipsiprymnus* and *K. defassa.* Closely related is the sing-sing, *K. defassa unctuosis,* of western Africa; its hair is not so coarse as that of the true waterbuck, and its coloration is more dominantly brown. Coloring of the waterbuck may vary from reddish brown to gray-brown. The neck hair is heavy, the tail is tufted. The males have long horns spreading out to form a broad-based V. The waterbuck has a band of white over the rump which does not appear in the sing-sing. All these species frequent watercourses; they are good swimmers. Some kobs of the related genus *Adenota* are frequently called waterbuck. The reedbuck is related, but smaller. The name is also written *waterbok.* (See ANTELOPE.)

WATERBURY, city, Connecticut, in New Haven County, one of the county's two seats, New Haven being the other. It is situated at an altitude of 280 feet, 32 miles northeast of Bridgeport, on the New York, New Haven and Hartford Railroad.

Location and Transportation.—Waterbury, fourth city of the state in population, following Hartford, New Haven, and Bridgeport, is approximately the same distance from each of these three cities. Hartford lies to the northeast, New Haven to the southeast, and Bridgeport to the southwest. The Naugatuck River, into which the Mad River flows near the city's southern boundary, empties into the Housatonic River 20 miles south of Waterbury. The city is the trading center for the northwestern section of the state. It has rail and motor bus and truck connections with other cities of the state, and fast service to New York and Boston.

Industries.—The chief seat of the brass industry in America is the Naugatuck Valley, of which Waterbury is the center. Its brass foundries produce brass and bronze to be further fabricated into sheets, rods and tubing. The mills also work in aluminum, steel, and many alloys. It produces a great variety of articles made wholly or in part of brass: buckles, wire, tubing, kettles, pins, clips, fasteners, eyelets, and many others. While brass is Waterbury's chief industry, its mills and shops produce many other kinds of goods: cutlery, automatic machinery, chemicals, buttons, metal hose, recording instruments, chromium and nickel plating, paper boxes, and so on. There are important machine shops and foundries. The manufacture of cheap watches was carried on here so extensively and successfully that the name "Waterbury watch" was known everywhere. The "dollar" watch also originated here. It is not so generally known that from the opening years of the 19th century Waterbury has been a leader also in the making of clocks. In 1914 Waterbury turned to the manufacture of war materials, and when war broke out again in Europe in 1939, and later when the United States program of production for defense was launched, the city's industrial activity was again accelerated. The Waterbury speed gears used on warships are made here.

Topography.—Waterbury is in the valley of the Naugatuck River, with hills on either side. The slopes roundabout have been largely denuded of their original cover of timber to supply fuel for the earlier brass works; ridges of granite hold the soil. The river flows through the city in a general north-to-south course; the railroad roughly parallels the stream, and the mills and shops follow the same line. The first settlement was on the west bank of the river (see section

History of this article); on the opposite side of the river and several blocks to the east is the civic center of today's community. About the Green are clustered the Masonic Temple, the Y.M.C.A. building, the First Congregational Church, Immaculate Conception Church, St. Johns Church (Episcopal), Hotel Elton, and various business and professional buildings. The streets are not laid out in geometric pattern, but present many irregular curves and angles. The Mad River flows through the eastern part of the city, then swings to the west and joins the Naugatuck.

Education and the Humanities.—Schools were at first administered by the town government, and later by a "school society." Under this latter control the town was divided into 14 school districts. In 1849, chiefly with a view to establishing a high school to take the place of the earlier academy, five of the districts were consolidated as a central district, and this was placed under the management of a board of education, a finance committee, and a superintendent. In the outlying districts the former system of control by a board of visitors was retained. In 1899 the control of the central district was simplified; the powers and functions of the earlier and somewhat cumbrous organization were concentrated in the board of education. Even when the city was made coterminous with the town in 1901, the traditional status of the outlying districts was preserved, but later the distinction was dropped and a system of unified control was adopted. The public school system includes kindergarten, grammar, and high schools, with departments of domestic science and manual training. There are parochial schools, elementary and high; Notre Dame Academy was established in 1869. Well known Waterbury schools have been Saint Margaret's School for girls (Episcopal, diocesan), and McTernan School for boys. The Silas Bronson Public Library was opened in 1870. The Mattatuck Historical Society, organized in 1877, was incorporated in 1902; it maintains colonial collections, a children's museum, and a genealogical library. Dating from the 1880's are the Waterbury Club and the Women's Club; from the 1890's, the local Daughters of the American Revolution, and the Naturalists' Club. The Waterbury branch of the Young Men's Christian Association was established in 1858, only six years after the first society in this country was formed. In addition to the customary social, civic, and service organizations, the city has many philanthropic and charitable enterprises, homes and hospitals. With these complementing its qualities as an industrial center, Waterbury makes liberal provision for the humanities of community life.

Parks and Monuments.—At one end of the Green stands a Civil War memorial, the Soldiers Monument, with cannon mounted about it. The sculptor was George E. Bissell; this particular one of his many works was done in 1883–1884. Bissell married Mary E. Welton of Waterbury. At the other end of the Green is a memorial fountain presented to the city by Caroline J. Welton, a Waterbury woman who was one of the group that organized the state humane society. The city's largest parks are Hamilton in the southeastern and Fulton in the northern sections. In 1939 the city completed a municipal stadium and athletic field. Hamilton Park contains a city zoo, athletic fields, swimming pools, drives and trails; in it is an old water wheel used about 1845 in a brass mill. Fulton Park has lawns and gardens; the rock garden especially is noteworthy. There is a bird sanctuary in this park. The park provides excellent recreational facilities. Riverside Cemetery, west of the Naugatuck, was opened in 1853, and is notable for its park-like beauty. Also on the west bank of the river, near the site of the first settlement, is Chase Park. At the entrance to the park, opposite a concrete bridge spanning the Naugatuck, is the Pilgrim Memorial, and a boulder with tablet marking the site of the first settlement.

Buildings.—The city hall and the public library are just south of the Green, in a triangle formed by Meadow, Grand, and Field streets. The municipal building is one of several in the city designed by Cass Gilbert (1859–1934), architect of the Capitol in St. Paul; the Essex County courthouse in Newark, N. J.; the Woolworth Building in New York, and of public buildings in many other large cities. Here in Waterbury are several specimens of his skill: the Chase Infirmary, the Waterbury Bank, and the Waterbury Club's house. The city hall is a three-story structure of marble and brick, with a belfry. It is approached through a formal garden, with a fountain. The Silas Bronson Library building is of brownstone; in its grounds stands a statue of Benjamin Franklin by the Connecticut sculptor Paul Wayland Bartlett (1865–1925), of whose work specimens are to be seen in the Library of Congress, the Stock Exchange in New York, the New York Public Library, in Boston, and in other cities. Between these buildings and the Green are the office building of a brass company, another Gilbert design, and the home of the Mattatuck Historical Society. Opposite the library is the railroad station, having a clock tower copied from one in Italy.

History.—Salient facts in the history of Waterbury are that it was settled in the 1670's; was set off from Farmington and incorporated as a town in 1686; received its charter as a city in 1853, and was consolidated with the town by a charter amendment in 1901. Some apparent discrepancy in the assigning of a date of settlement is accounted for by the fact that in 1674 families from Farmington (itself settled in 1640 by migrants from Hartford, and incorporated some five years later) settled on the high land on the west side of the river; the site of this settlement has ever since been known as the Town Plot. This settlement was abandoned in King Philip's War, and in 1677 a new one was made, on the other side of the river, nearer to Farmington; this second site has been known as the Town Spot. The 31 householders who formed the settlement, upon order of the General Court and payment of some £2,500, built their houses about the Green; it is said they entered into an agreement fixing the minimum dimensions of the houses at 16 by 18 feet. Settlement of Connecticut antedated the foundation of Waterbury by only four decades; it was in the 1630's that colonists from Massachusetts began reaching out to the west for new lands and new homes. Their first settlements were planted in the Connecticut Valley; for Hartford, the year was 1635. New Haven was settled in 1638. By the time of Waterbury's permanent settlement the colony of Connecticut had received its royal charter, and was developing such powers of self-government as the colonial system per-

mitted, and (as is perceivable in retrospect) developing the American ambition for independence which in another century was to bring on the Revolution.

The site of the Waterbury settlement was called by the Indians "Matetacoke," meaning "land without trees." This name was contracted to Mattatuck, and that was the name under which the town received separate incorporation, upon being cut off from Farmington, of which it was originally a part. At the time of that incorporation, 1686, the locality was a part of Hartford County. For more than a century the town's growth was slow. In addition to the natural disadvantages of its situation for a community dependent upon agricultural pursuits it underwent such setbacks as the "great flood" of 1691 and the "great sickness" or epidemic of 1712. Long afterward, in 1902, the city's business section was destroyed by fire.

With the advent of the 19th century, Waterbury's history moved over into industrial territory. The very conditions that had surrounded the settlement of the town and limited its agricultural prosperity became now an important and favorable factor in its development. Under the discipline of poverty and hardship a group of men had grown up who possessed inventive genius, initiative, ideals of thrifty administration, endurance, and determination to achieve. The farmers' sons became manufacturers, makers of clocks and buttons. The streams furnished power for small mills and factories, whose products met the growing demands of the time. It was in response to these demands, emphasized by the War of 1812, that Waterbury began to establish itself as the center of the brass industry. Crude early methods of manufacture were superseded by new processes. Skilled artisans were brought in from England. These Connecticut Yankees were not mere imitators; they added skill to skill, and improved upon their models.

Population.—Waterbury's industrial history has a supplement in the steady inflow of workers of foreign birth or descent. When the first federal count was taken, in 1790, Waterbury's population was somewhat less than 3,000. In 1850 it was 5,137; and in 1900, 51,139; in 1940 it was 99,314, and in 1950, 104,477.

WATERBURY, town, Vermont, in Washington County, ten miles north-northwest of Montpelier, at an altitude of 425 feet, in the valley of the Winooski River; and on the Central Vermont Railroad. It contains the villages of Waterbury and Waterbury Center. Industrial enterprise centers upon woodworking and the processing of dairy products. There is a public library in Waterbury village; it has a museum. A state hospital for the insane is located here; it has farms, a laundry, and a cannery for its own maintenance. In 1927 the village suffered heavy loss of life and property, when floods swept through the streets and washed many buildings from their foundations. Two miles distant is Green Mountain Power Plant No. 1. It is in a gorge at a spot where an island of rock breaks the river into two swift channels, and the water boils over projecting ledges. On the edge of the gorge is a lookout. Pop. (1950) 4,276.

WATERCOURSES, *in law,* streams of water usually following a well-defined channel and emptying into some other body of water. A watercourse need not maintain a constant current, but it must be more than an occasional stream, the result of unusual rains or the melting of snow and following a channel customarily dry. See RIPARIAN RIGHTS.

WATEREE, a river of South Carolina, formed by the junction of the Catawba River and Fishing Creek, and is called the Catawba in the upper part of its course. It is about 315 miles long and runs nearly southward, forms the east boundary of Chester, Fairfield and Richland counties, and unites with the Congaree River at the southwest extremity of Sumter County to form the Santee River.

WATERFALL, a sudden descent in the water of a river or stream from a higher to a lower level. When the water falls over a precipice it is called a cataract, and when several cataracts occur in succession it is called a cascade. Where the incline is less steep and there is merely a stretch of very swift and tumbling water, the term rapid is commonly used. Some of the mountain waterfalls are remarkable for their height, while others are noted for the fall of immense quantities of water.

The most remarkable waterfall in the world is Niagara Falls on the Niagara River, between lakes Erie and Ontario, and thousands of visitors from all parts of the world have admired the sublimity of these falls. Waterfalls are now being utilized to furnish both electric and water power for commercial purposes. The falls discovered by Dr. Livingston in Africa and named by him Victoria Falls, the falls of the Ruikanfoss in Norway, the Cascade of Gavarnie in the Pyrenees and the falls of the Rhine are among the most beautiful in the world, and justly celebrated. Falls are characteristic of a youthful stage of river erosion, and are usually caused by unequal hardness of the rock, the softer being worn down the faster, and giving rise to inequalities in the river bed. After the softer beds are cut down as low as they can be eroded, the rivers more slowly cut away the harder layers, and the fall gradually disappears. For a fuller description see CATARACTS.

WATERFORD, town, Connecticut, in New London County, at an altitude of 44 feet, 3 miles southwest of New London, served by the New York, New Haven and Hartford Railroad. It has textile and paper mills. Incorporated in 1801, it is governed by a board of selectmen. Pop. (1950) 9,100.

WATERFORD, maritime county, Ireland, in the province of Munster, bounded on the north by Tipperary and Kilkenny, on the east by Wexford, on the south by the Atlantic Ocean and on the west by Cork and Tipperary. Its greatest length is 51 miles and greatest breadth, 23 miles. The name derives from the Danish Vadre-fiord. The Gaelic name is Port Láirge. The Knockmealdown Mountains run east and west between Waterford and Tipperary. The chief harbors are Waterford and Tramore. The Blackwater is the chief river. Main towns are Cappoquin, Dungarvan, Lismore and Waterford. Until recently there was a part of the eastern portion of the county called the Decies where the language of the people was entirely Gaelic. The occupation of the people in nonurban areas is farming. Area 454,278 acres. Pop. (1951 prelim.) 75,062.

WATERFORD, city, Ireland, capital of County Waterford. It is about 100 miles due south of Dublin and is situated on the southwest bank of the river Suir. It is connected with Ferrybank, on the opposite side of the river, by a ferroconcrete bridge, 832 feet long. Waterford is an important railway station on the line running from Mallow to Wexford and Rosslare, in connecting with the cross-channel service. The Gaelic name for the city is Port Láirge. The town was founded by the Danes in 873 A.D. but its authentic history may be considered as beginning with the arrival in 1170 of Strongbow and a large force of Anglo-Norman invaders. After slaughtering most of the inhabitants Strongbow married Eva, daughter of the King of Leinster. Hook Head and Crook Head are promontories near the city and it is said that the phrase, "by hook or by crook" arose from a statement made by one of the invaders that if he did not get in by Hook he would get in by Crook.

Waterford harbor is not especially good but vessels drawing 22 feet can discharge at the quays. The local industries include breweries, foundries, jute, margarine, bacon, flour mills, polish, and glass factories. It is here that the famous "Waterford Glass" originated. Pop. (1951 prelim.) 28,689.

WATERFORD, village, New York, in Saratoga County, on the Hudson River at the mouth of the Mohawk River, 10 miles north of Albany at an altitude of 38 feet and served by the Delaware and Hudson Railroad. Here is the junction of the Champlain and Erie divisions of the State Barge Canal which entails the handling of canal traffic, a considerable item in the local industrial schedule. Settled by the Dutch out of Albany about 1640, the village originally was named Half Moon after Henry Hudson's ship whose crew explored the Hudson River as far as Waterford in 1609. The village, incorporated in 1794, is the business center. Contiguous is an industrial and residential area known as Waterford Town.

Waterford has an important place in history. Originally a trading center it was for many years the center of fierce fighting between various Indian tribes. In 1691 Waterford was the site of Half Moon Fort, a defensive outpost against the Canadian Indians. Here was the crossing place of Abercrombie's 1758 army, later defeated at Ticonderoga; here Kosciusko, under General Schuyler, erected earthworks to stop the advance of General Burgoyne; and it was here that Thomas Moore, the Irish poet, wrote a poem after visiting the neighboring Cohoes Falls. On Haver Island is a bleachery connected with the manufacture of shirts and collars. Also here are important chemical plants and valve works. Pop. (1950) Waterford Village, 3,025; Waterford Town, 6,075.

WATERHOUSE, Alfred, English architect: b. Liverpool, July 19, 1830; d. London, Aug. 22, 1905. He studied architecture under Richard Lane in Manchester and afterward in France and Italy. He began practice in Manchester in 1853 and first made his name known by the Assize Courts of that city. For the same city he afterward designed the county jail, Owens College, the town hall, Saint Mary's Hospital and other buildings. In other parts of England he was responsible for the following among other buildings: in Liverpool, Seaman's Orphanage, Turner Memorial Home, Royal Infirmary and University College; in London, Natural History Museum, New St. Paul's School, City and Guilds Central Institution, King's Weigh House Chapel and University College Hospital; in Oxford, Balliol College (partly rebuilt); in Cambridge, Caius and Pembroke colleges (partly rebuilt); in Leeds, Yorkshire College; the mansions of Eaton Hall (Cheshire), Heythrop (Oxford), and Iwerne Minster (Dorset).

He was elected an Associate of the Royal Academy in 1878 and Royal Academician in 1885, and in 1898 became treasurer of the academy. He received a Grand Prix from the Paris exhibition of 1867 and was a member of various foreign academies. In 1878 he was awarded the gold medal of the Royal Institute of British Architects, of which he was president 1888–1890.

WATERHOUSE, John William, English painter: b. Rome, Italy, 1849; d. London, Feb. 10, 1917. He studied at the Royal Academy but was largely self-taught. His paintings are noted for the richness of their coloring. His paintings include *The Oracle* (1884); *Echo and Narcissus*; *The Magic Circle; The Lady of Shalott; La Belle Dame sans Merci; Hylas.*

WATERLAND, Daniel, English clergyman: b. Lincolnshire, Feb. 14, 1683; d. Dec. 23, 1740. He studied at Cambridge, became master of Magdalen College, chaplain to George I and canon of Windsor. Waterland was an able defender of the Orthodox faith against the Deists. His chief writings are *A Vindication of Christ's Divinity, being a Defense of some Queries relating to Dr. Clarke's Scheme of the Holy Trinity* (1719), followed by a second (1723) and third (1725) *Vindication;* a *Critical History of the Athanasian Creed* (1724), also directed against Clarke; *Christianity Vindicated Against Infidelity,* a reply to Tindal's *Christianity as old as the Creation;* and a *Review of the Doctrine of the Eucharist* (1737), directed against Hoadley's rationalistic theory of that ordinance.

WATERLOO, city, Illinois, seat of Monroe County, 26 miles south of St. Louis, Mo., on the Gulf, Mobile and Ohio Railroad. It is situated at an altitude of 717 feet in a fertile agricultural region, in which the chief products are wheat and corn. In the vicinity are quarries of fine building stone, known in the trade as Waterloo marble. The chief manufacturing establishments are flour mills, marble works, an ice factory and a hatchery. There are large stockyards and coal and lumber yards. The educational institutions are a high school, founded in 1891, public and parish elementary schools and a school library. Until the passage of strict marriage license laws in 1937 the city was known as the Gretna Green of the St. Louis area. Pop. (1950) 2,821.

WATERLOO, city, Iowa, Black Hawk County seat, 52 miles northwest of Cedar Rapids on the Cedar River, and on the Illinois Central, the Chicago, Rock Island and Pacific, the Chicago Great Western, and the (electric) Waterloo, Cedar Falls and Northern railroads, and three federal highways. At an altitude of 856 feet, it is in a farming, dairying and stock-raising region, and is headquarters of the National Dairy Cattle Congress and the Na-

tional Belgian Horse Show. There is abundant and cheap power from the Cedar River, here about 800 feet wide. The Illinois Central has big repair shops here. Factory products are: meat packing, tractors and other farm and dairy machinery, washing machines, soy bean processing, caskets and refrigerators. The city has 12 parks with a total area of 350 acres. The educational institutions include public elementary and high schools—the East High School, founded in 1872, and the West High School, in 1870, and four junior high schools. The Roman Catholic Church maintains four parochial elementary schools and one high school. There are two business colleges. The city has two public libraries and five hospitals. There is a symphony orchestra. The *Courier,* evening and Sunday newspaper, was established in 1858.

The settlement was first known as Prairie Rapids, the name given to it by the Hanna family, its first settlers. The name became Waterloo in 1851. The city was settled in 1845–1846 and was incorporated in 1868. The growth of the city was very rapid. The government is vested in a mayor and a council of six members elected every two years. Pop. (1950) 65,198.

WATERLOO, village, New York, one of the two Seneca County seats on the Seneca River, midway between the northern ends of Seneca and Cayuga lakes, 57 miles southeast of Rochester at an altitude of 450 feet and on the New York Central, and the Lehigh Valley railroads. Fine farm country surrounds the village. Waterloo's industries are the making of sauerkraut and pickles, canning, and production of automobile bodies. In the center of the village is Lafayette Park, beside which stand the county buildings and a modern high school. Pop. (1950) 4,438.

WATERLOO, a manufacturing city in Ontario, Canada, in the county of the same name, immediately adjacent to the city of Kitchener (q.v.) with which it is connected by electric railway. It is surrounded by an excellent mixed farming and dairying district traversed by highways which supplement the services of branches of the Canadian National and Canadian Pacific railways. Of its 54 industries, the most important is one of the largest liquor distilleries in Canada. There are also ten furniture factories, as well as large manufactories of bicycles, miscellaneous cotton goods, cooperage, paper boxes and bags, and agricultural instruments. The total value of industrial products is $29,096,975 representing the employment of 2,647 persons (1949). Waterloo is also noted as the headquarters of three life and two fire insurance companies, a health and accident insurance company, and a trust company. The city has ten churches, three public schools, a separate school, a collegiate institute, a technical school, a public library (16,957 vols.), a park and tourist camp, a weekly newspaper, an airport, four banks, and a Chamber of Commerce.

The county of Waterloo was to a considerable extent settled by Mennonites ("Pennsylvania Dutch" in local parlance) who came from the United States soon after 1800, and over 60 per cent of its present population derives from that origin. This conduced to the establishment in Waterloo city of a Lutheran Evangelical Seminary in 1911 which developed into the Waterloo College School in 1914 and into the Waterloo College of Arts in 1925. The latter is now an affiliated college in Arts and Theology of the University of Western Ontario (London). Pop. (1951) 11,079.

WATERLOO, county town, Quebec, Canada, in Shefford County, about 60 miles southwest of Montreal on the Canadian Pacific and Canadian National railways. Waterloo Lake on which the town is situated is an expansion of the Yamaska River. There are 18 local industries which employ 758 persons and manufacture to the value of $4,339,105 (1949), the two largest being a manufactory of plastic products. The town was incorporated in 1890, though the neighborhood (devoted to mixed farming) was settled early in the nineteenth century. There are three churches, a classical college, a high school, a convent, a business college, two weekly newspapers, two banks, and two public parks. Pop. (1951) 4,027.

WATERLOO, town, Sierra Leone colony, Africa, on the Sierra Leone Peninsula, 17 miles southeast of Freetown, with which it is connected by a narrow gauge railway. It is a center for trade in kola nuts, ginger and rice. It was the site of the colony's chief airfield until 1948 when it was removed to Lungi, 10 miles north of Freetown. Founded in 1819, it has a Roman Catholic mission. Pop. (1931) 2,312.

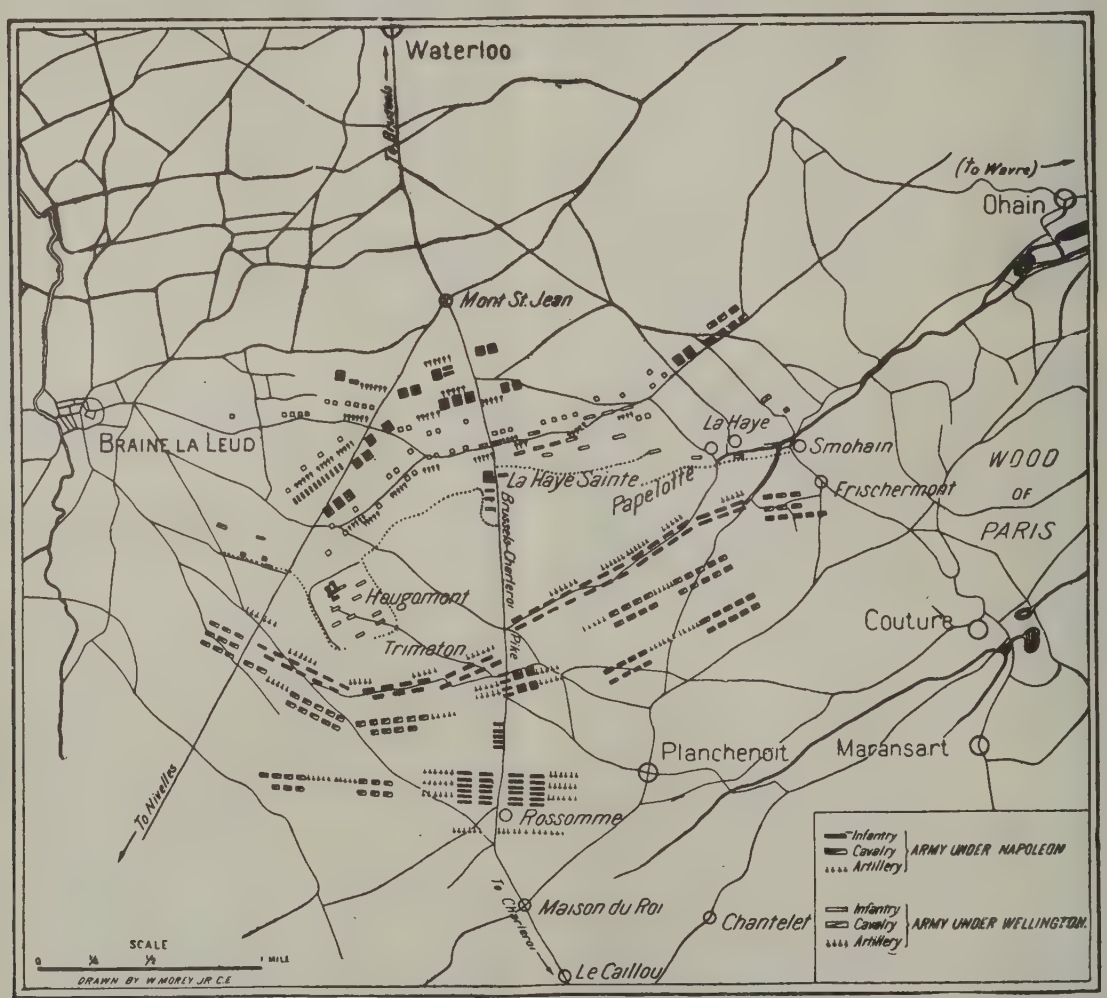
WATERLOO, village, Wisconsin, in Jefferson County, 21 miles northeast of Madison. Situated in a dairying region, its manufactures are chiefly dairy products. Pop. (1950) 1,667.

WATERLOO, Battle of, the culminating engagement of the shortest and most decisive of all of the Napoleonic campaigns, was fought June 18, 1815, near the village of Waterloo, in Belgium, situated about 12 miles south of Brussels. From April 11, 1814, when Napoleon signed the first abdication and retired in exile to Elba, until March 20, when he terminated the period of that retirement and returned to Paris, the political and domestic affairs of France had been bordering on revolution. Although the administration of affairs by the government established by the Comte du Provence, who, under the title of Louis XVIII, had taken unopposed possession of the country, restored political liberty, the changes inaugurated were so sudden, that they unsettled all domestic affairs, the title of estates, the position of public men, and the prospects of the army to an intolerable extent. A general sense of alarm and humiliation prevailed among all classes, and even a Napoleonic period seemed preferable to the existing conditions. To add to the general turmoil, about 300,000 troops who had been held as prisoners in the various German fortresses were released under treaty stipulations and returned to France. Their apparent availability for further operations soon formed the basis for innumerable military plots of which that designed by Fouché, with the ultimate object of placing either the duke of Orleans or the king of Rome upon the throne, was the most important.

Napoleon was fully conscious of the existing state of affairs. France was down, groveling at the feet of the Allies. Here was the

opportunity for a truly patriotic action. He would give popular liberty to imperial France, and henceforth devote all his energies to strengthen that liberty and increase that prosperity. He counted upon the enthusiastic support of the army which was fretting under the command of emigrés who had once fought against France, but were then being appointed to important commands, and felt sure of the effect of his tremendous military fame upon the general military feeling of the country. He thought of Marengo; how in three short months he had lifted France and himself from

army amounted to about 500,000 men, on paper, but only about 200,000 men were available for actual field service. In planning the campaign, Napoleon had the choice of confining himself to purely defensive operations and allowing the Allies to invade France, or of assuming the offensive, and relieve her of the consequences of a second invasion. He chose the latter, and laid the scene of the campaign in Belgium where the English under the Duke of Wellington had their headquarters at Brussels, and the Prussians under the command of Marshal Blücher, at Namur.



Field of Waterloo. (Showing positions of the two armies at 11 A. M., 18 June 1815).

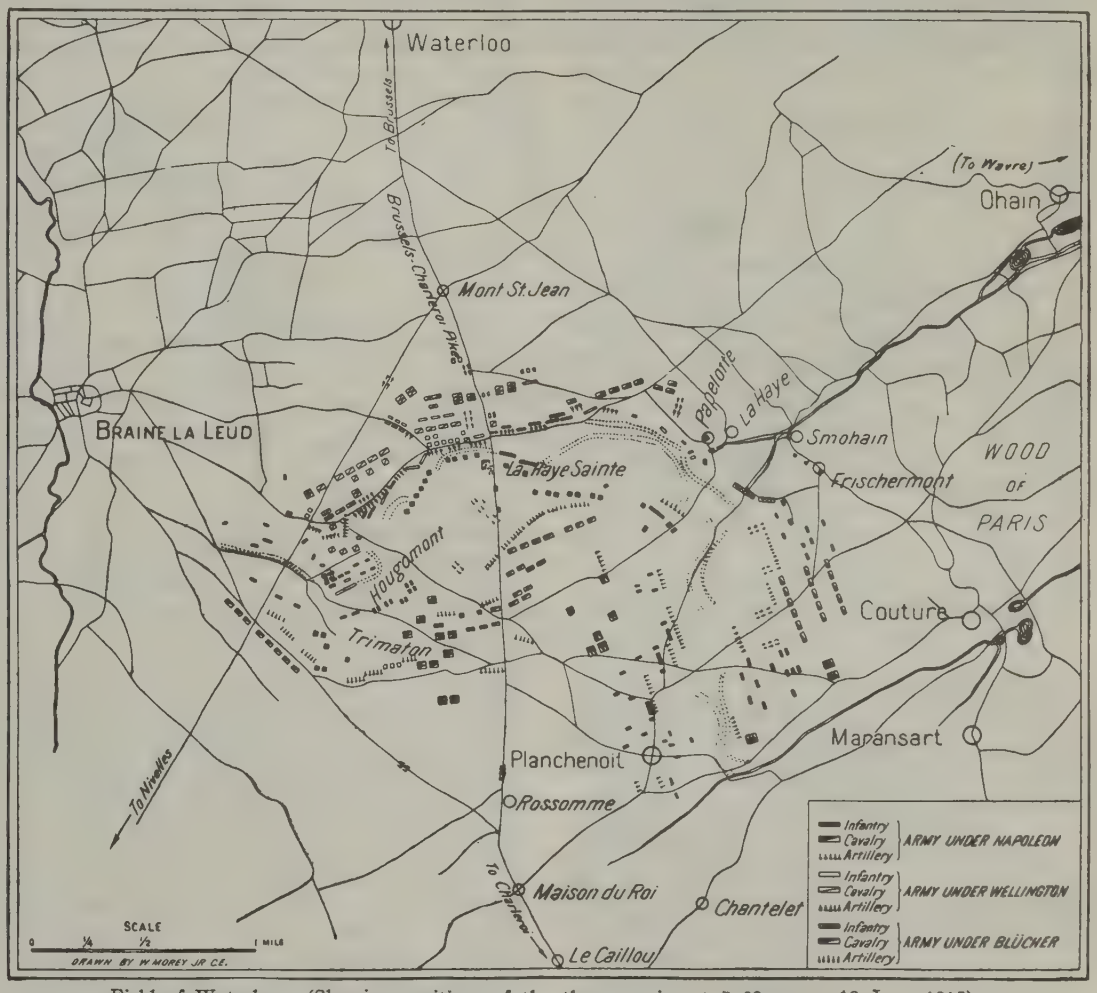
the lowest ebb of fortune up to the highest pinnacle of military glory and power. He judged correctly in all these things. He left Elba 20 February, and landed on the coast of France 1 March, and entered Paris triumphantly 20 days later.

While Napoleon was inaugurating the Hundred Days with professions of peace and liberty, the Allied Powers suspended negotiations at the Congress at Vienna, issued a declaration branding him as "an enemy and disturber of the peace of the world," and formed a new Coalition to renew the struggle against him. By the beginning of June they had more than 700,000 men in the field, and he was compelled to take active measures to defend his newly recovered empire. The French

The general plan of operations was based upon his favorite form of strategy — action on "interior lines" against the two armies opposed to him. He assumed that Wellington and Blücher would endeavor to form a junction at Charleroi, and determined to concentrate the bulk of his own army at that point and defeat them separately before they could effect that junction, and then turn his attention to the force of Austrians and Russians gathering on the eastern border under the command of Prince Schwarzenberg.

At the beginning of the campaign the French army numbered 124,588 men — 89,415 infantry, 23,595 cavalry, 11,578 artillery with 344 guns. Wellington commanded 93,717 men — 69,829 infantry, 11,879 cavalry, 9,406 artillery and

engineers, with 196 guns. The Prussian forces under Blücher amounted to 120,954 men—99,715 infantry, 11,897 cavalry and 9,360 artillery, with 312 guns. Wellington's forces, composed of Englishmen, Dutch, Belgians, Nassauers, Germans and Brunswickers, were stationed in numerous cantonments scattered over a large area around Brussels, and to the westward of the Brussels-Charleroi pike leading to the south, with the coast as their base. Of Blücher's force the First corps, under Ziethen, was at Charleroi, the Second, under Pirch, at Namur, the Third, under Thielmann, at Ciney tacked the Prussians at Ligny, and after three hours of severe fighting, defeated them and captured 21 guns. The battle was desperate and bloody; about 12,000 Prussians fell, and in the final charge of the Guard, Blücher himself was wounded. This was Napoleon's last victory. As the result of the battle, he assumed that the Prussians had been routed and were retreating to their base by way of Namur and Liège, when, as a matter of fact, under the direction of Gneisenau, Blücher's chief of staff, they were moving northward and converging on Wavre, with the intention of join-



Field of Waterloo. (Showing positions of the three armies at 7.30 P. M., 18 June 1815).

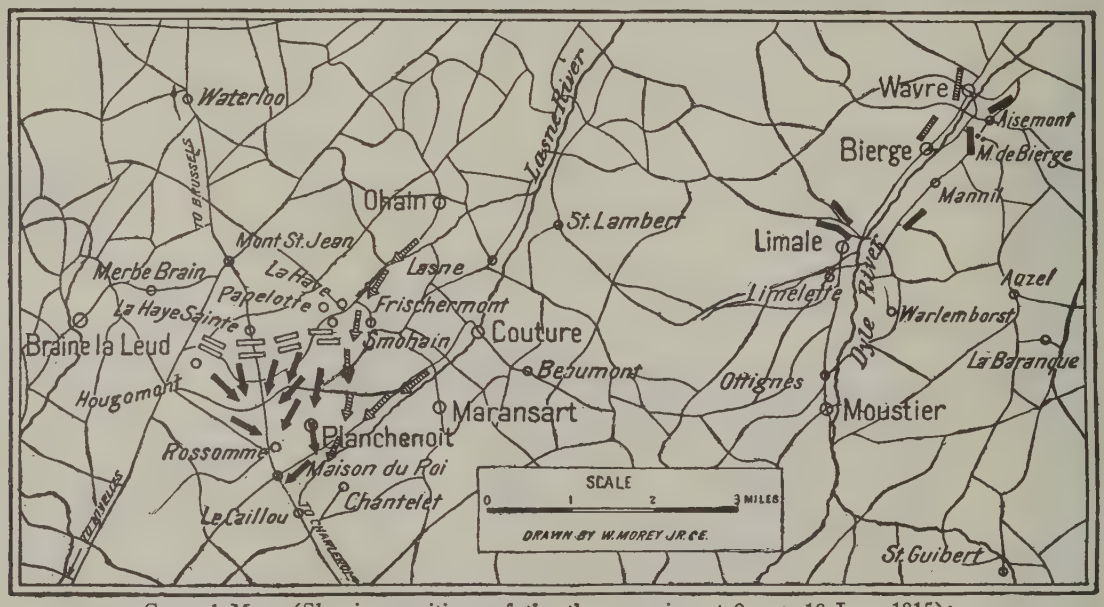
and the Fourth, under Bulow, at Liège, with the Rhine as their base.

The movement began on 13 June. The French army advanced rapidly northward, crossed the Sambre on the afternoon of the 15th, attacked Ziethen's position, drove him back upon Fleurus, and occupied Charleroi. A portion of the army then continued the advance through Gossilies to Quatre-Bras where they met a force of 25,000 men under Wellington, on the afternoon of the 16th, and after several hours of hard fighting were driven back upon Frasnes. In the meantime, with the intention of blocking the road between Quatre-Bras and Sombreffe so as to separate the forces under Wellington and Blücher, the troops commanded by Napoleon himself at-

ing Wellington, with whom they were in constant communication. About noon of the 17th, Napoleon detached Grouchy with 33,000 men to pursue and complete the defeat of the Prussians driven back at Ligny, while he himself with the main body of the army joined Ney and followed Wellington, who, although victorious at Quatre-Bras, had been forced to fall back northward toward Brussels on account of the defeat of the Prussians at Ligny. Wellington's retrograde movement was continued during the whole of the 17th, until he had reached the heights of Mont Saint Jean, about four miles south of the village of Waterloo, where the Prussians could join him by way of Ohain and Wavre. Here he selected his position, and confident of their assured

support, he awaited the advance of the emperor.

On the afternoon of the 17th, when Napoleon reached Marbain, he received the information that the Prussians defeated at Ligny had not retreated to Namur and Liège, and he sent a message to Grouchy informing him of that fact, and instructing him to find out if the Prussians were moving to a junction with Wellington. When Grouchy received this message he was actually farther from the Prussians than the Prussians were from Wellington, and about the time he reached Gembloux, about 10 o'clock on the night of the 17th, only



General Map. (Showing positions of the three armies at 8 P.M. 18 June 1815):

rear of Wellington's position, and thus cut off his retreat in the direction of Brussels and his base of supplies. The best authorities concede that the plan was admirably conceived.

About 8 o'clock on the morning of the 18th, Wellington drew up his forces in line of battle, but although the rain which had been falling all night ceased about that time, the attack by the French was postponed so that the ground might be in better condition for artillery movements. A little before 9 o'clock Napoleon reviewed his lines, and about 10 o'clock he sent instructions to Grouchy to advance upon the Prussians at Wavre. The battle commenced

to learn that the Prussians had really marched to Wavre, the main French army had reached the field of Waterloo and bivouacked opposite the forces of Wellington. It was past midnight when Napoleon inspected the position of both armies. The main line of Wellington's forces occupied an advantageous position along the highway that runs from Braine la Leud to Wavre by way of Ohain, with the centre resting on the Brussels-Charleroi pike, while strong outposts held the farm house of La Haye Sainte directly in advance of the centre, the hamlets of La Haye, Papellotte, and Smohain on the extreme left, and the chateau of Hougomont on the right. His force consisted of 67,661 men — 49,608 infantry, 12,-408 cavalry and 5,645 artillery with 156 guns. Of these the British troops numbered only about 24,000. Napoleon had 71,947 men — 48,-950 infantry, 15,765 cavalry and 7,232 artillery with 246 guns. He arranged his troops in two lines diagonally across the Brussels-Charleroi pike, the right resting on Frischermont, and the left across the road to Nivelles, with a strong force of infantry, cavalry and artillery stationed in the rear on both sides of the Charleroi pike near Rossomme.

Early on the morning of the 18th, he dictated his plan of battle, the direct object of which was to capture the village of Mont Saint Jean lying on the Charleroi pike directly in the at 11.30. As a diversion, a division of Reille's corps assaulted the British position at Hougomont, were repulsed, and were supported by division after division until the entire Second corps were in action against Wellington's left, and therefore did not take any part in the main attack on the British centre by D'Erlon about 1.30. In this attack, the advanced troops of the British right, composed of Bylandt's brigade, were easily routed, but the advancing French received a terrific fire from Picton's brigade, and being charged by the British cavalry, fell back in great disorder. Here General Picton who probably commanded the British right was killed. In the meantime, assault upon assault was made by the French on La Haye Sainte, which occupied the greater part of the afternoon, while for two hours, from 4 to 6 o'clock, under the personal direction of Ney, the splendid cavalry divisions of the French were hurled against the British right-centre, but failed to break the formation of a single British square. The cavalry attack being unsupported by infantry, Ney was compelled to withdraw for lack of troops, about 6.30, just as La Haye Sainte was taken, too late to be of any advantage. About the middle of the afternoon Napoleon discovered the advance guard of the re-enforcing Prussians on the hills of Saint Lambert about three miles away upon his right, and realized for the

first time that the entire Prussian force had succeeded in concentrating at Wavre, and were now on hand to aid Wellington. He immediately detached Lobau with the Sixth Corps, to intercept the new enemy, and sent a message to Grouchy, ordering him to return. Grouchy in the meantime, having moved off to Wavre in search of the Prussians, did not get this message until evening.

Lobau being unable to check the advance of the Prussians, the Young Guard was sent to re-enforce him, and then, believing that his right was secure, Napoleon massed the eight remaining battalions of the Imperial Guard for a final attack upon Wellington's center. Supported by a terrific artillery fire, and led by Friant, the Guard advanced, while D'Erlon hurled the First Corps against the British right. D'Erlon's assault was effective, but the Guard, decimated by a heavy fire from Maitland's brigade, supported by those of Halkett and Elphinstone, were repulsed with terrific loss and fell back in complete disorder before the impetuous charge of the 52d regiment. Just then, about 7:30, the main body of the Prussians arrived, and going right into action, attacked the French right and threw it into confusion. At that moment, Wellington, seeing that victory was assured, ordered a general advance of his lines and decided the contest. His troops, however, were too far gone to engage in the pursuit, which was taken up by the Prussians with vigor, and the retreat soon became a rout. Napoleon left the field in the center of a square of the Imperial Guard. He left this at Genappe, and arrived at Charleroi at daybreak with a small escort of horsemen. He reached Paris 21 June, and signed the second abdication on the 22d. The entire campaign had lasted but three days, and the battle itself, one of the most remarkable and terrible of modern times, was decided in eight and a half hours. The French lost in killed, wounded and missing, about 31,000 men, and the Allies, about 23,000.

WATERMELON. See Melons.

WATERPROOFING, the art of rendering various substances impervious to the penetrating action of water. The purposes to which waterproofing is now applied are very numerous and the methods range from the early use of lead for sheathing building foundations, of tar for tarpaulin, oil for oilskin, rubber for clothing, to various painting processes which claim for bases, substances capable of resisting the natural action of the elements, and which, invisible, impenetrable, insoluble and imperishable, effectually render brick, stone, marble, terracotta, stucco, concrete, etc., impermeable to water. These processes are used to waterproof and insulate exterior and interior walls of buildings, for cold storage plants, for the lining of reservoirs, for monuments, etc.

Among the numerous methods of waterproofing, many of which are protected by patents, the greater number in general relate to a surface application of some composition, usually somewhat thicker than an ordinary liquid solution. The more widely known methods of waterproofing are those used in connection with paper and paperboard, textile fabrics, cloth, with cordage, leather, etc.

Paper.—The commonest process for waterproofing paper and manufactures of paper is their saturation with wax or paraffine; either by the use of heat, or in solution, as with benzol. Flexible papers (and woven fabrics also) of an absorbent nature may be made waterproof by a half-and-half mixture of a vegetable oil—such as China wood oil, linseed oil, poppy seed oil or soya bean oil—with polymerized cumarone. The mixture is heated for a time, and after being allowed to cool, is dissolved in a volatile solvent, which is applied with a brush, or by dipping the material into the solution and draining off the surplus. This treatment does not affect the folding qualities of papers, practically doubles the tensile strength, and renders the sheet transparent. One of the newest methods, recently patented, consists in saturating the paper with an ammonia soap of stearic acid emulsified with paraffin and diluted with water. The paper is passed through a tank containing tne emulsion, and thence is taken over a series of drying rolls to evaporate the water. A French process recently introduced consists in coating the paper with a vegetable mucilage, and, after this is dry, applying a coat of agar-agar. The paper thus prepared is then subjected to the steam arising from a bath made by adding four pounds of formol and five pounds of potassium bichromate to six quarts of water. This process renders the paper somewhat brittle, and to restore flexibility it is sponged with a weak dilution of glycerine. The so-called Japanese waterproof paper is made by pasting two sheets of paper together, the fibers crossing, with a secret waterproof cement.

Textiles.—Water-repellent textiles may be grouped into two classes according to their nature, first, the coarser tissues used for awnings, tents, oilskins, tarpaulins or canvas coverings for exposed merchandise, etc.; secondly, the finer tissues employed for the manufacture of waterproof clothing. The processes employed are of two classes, mechanical and chemical. In the first, a solid layer of some impermeable substance is laid upon the material The substances, usually applied are india rubber, varnish, resin, pitch, tar, paints, etc. These are also impervious to air. The agents in use for chemical waterproofing are aluminum sulphate, common alum, lead acetate, copper sulphate, zinc sulphate, iron sulphate, ammonium cuprate, potassium chromate, paraffin, ceresine, wax, soap, etc. In waterproofing loosely woven fabrics it becomes necessary to fill up the interstices between the threads with imperviable

material as well as to waterproof the threads themselves. It follows that a textile which is to be waterproofed should be very tightly woven so that when the individual threads are made impervious to water the cohesion of water falling upon it will prevent its separation into particles so small as to be able to pass between the threads. The earliest process consisted in covering the tissue with tar, a method still employed for marine supplies, ropes, cordage and coverings, and which has the advantage of giving solidity to the fibre, and at the same time preserving it. Drying oils, and particularly boiled linseed oil, are still largely used to waterproof coarse tissues, and particularly for the oilskin overalls worn in rough weather by sailors and fishermen. Oiled tissues, however, are heavy and lack comfortable suppleness, while their color and appearance militate against their extended use. One of the more widely employed processes for waterproofing the coarser tissues consists in impregnating the material with an insoluble soap such as those formed with copper, iron, zinc and alumina. Copper soap is most universally used. The material to be waterproofed is first scoured by boiling with soda lye and then washed, after which it is passed through a 20 per cent ammonia soap bath, then immersed in an 8 per cent solution of sulphate of copper. According to its nature, the fibre absorbs a certain quantity, large or small, of copper soap. In the ashes produced by the burning of a square yard of canvas or linen tissue so treated, as much as 57½ grammes of copper is found, and nearly 29 grammes of copper is to be found in the cinders of the same quantity of cotton tissue. Copper-soap waterproofed materials present a characteristic greenish tint.

The manufacture of waterproofed materials for clothing has attained considerable importance. The fact, however, must be recognized that the results generally obtained are not altogether satisfactory, especially from a hygienic point of view. Absolute waterproofing cannot be obtained without wholly closing the pores of the tissue; thus prepared it is an efficacious protection from rain and from contact with water, in certain cases is of real service, but inconveniently prevents ventilation. While the garments are made watertight they are at the same time made airtight. The perspiration and natural moisture of the body are not allowed to escape, but are held in saturation in the clothing, rendering it impure, damp and uncomfortable. The body is kept damp, and upon removing the outer garments the wearer is liable to chills and colds, hence, such waterproofing is unsuitable for prolonged personal wear.

The most diverse substances can be used for waterproofing textiles, if they are soluble in a liquid other than water, and can be spread over the surface of the material,—if they possess a certain suppleness, and neither alter the fibre nor the color of the tissue. Wax, balsamic gums, isinglass, spermaceti, metallic soaps dissolved in essential oils, a solution of shellac with borax are employed in waterproofing tissues. The cloth, whether of silk, cotton, flax or wool, is usually rendered waterproof by the application of some solution of any of these substances to one or both surfaces. In many of the earlier processes, the cloth was immersed in a liquid, so as to become saturated with the waterproofing agent. An early patent was obtained for a method of rendering cloth waterproof without concealing its textile surface; the cloth in the first place is saturated with a waterproof composition; it is then dried on one side to form a hard film, while the other side is kept moist, and is afterward deprived of its composition by means of spirits of turpentine.

Frequently silk tissues are waterproofed by the use of gelatine rendered insoluble by an alumina soap. The material is impregnated by passing it through cylinders covered with swanskin, afterward being steam dried. Woolen tissues are passed through a solution of acetate of alumina obtained by treating ordinary alum with acetate of lead. The process most extensively in use at the present day is the acetate of alumina treatment. The fabric is steeped in the acetate solution for 12 hours, the temperature being kept at about 95 degrees, special care being taken that it shall not reach 100 degrees. Much difficulty in securing an even distribution of the acetate throughout the fabric is avoided by the use of the "jigger," a machine which takes the cloth on a reel and passes it continuously through a vat containing the chemical, winding it upon another reel. When it has all passed the machine reverses and rewinds the cloth on the first reel; repeating this alternation again and again. By this process the time of saturation is reduced to five hours. A still more effective method of saturation is by the vacuum process. The reel of cloth is placed in an airtight drum and the air is exhausted. The acetate liquor is then allowed to flow in, filling the cylinder. Air pressure to the extent of two and one-half to three atmospheres is applied, and allowed to remain for 45 minutes, when the operation is complete. The cloth then goes to the drying room where the temperature is kept well above 100 degrees, in order that the acetate may be changed by the heat to the insoluble basic acetate of alumina. In this condition the fabric is sufficiently waterproof for most purposes of wearing apparel. If it is required that it be absolutely waterproof, it may be made so by immersion in a 5 per cent solution of soap. An insoluble aluminum soap is formed on the fibre of the textile and adheres firmly. The fabric will now have a slippery feel, and this is quite objectionable. It is readily removed, however, by passing the goods through a solution of common alum of the strength of 1 degree or one and one-half degrees Beaumé. With some manufacturers it is a practice to add india rubber or paraffin to fortify the protection given by the insoluble aluminum soap. This is readily accomplished, as the soap solution easily forms an emulsion with melted paraffine or with a solution of rubber in a mixture of linseed and palm oils. A highly recommended formula directs that chopped-up india rubber be dissolved in twice its weight of a hot mixture of petroleum and linseed oil; and that to this be added three times its weight of Japan wax. When well mixed, a small quantity of liver of sulphur is to be worked in. This mass is then to be stirred into a boiling mixture of olein, linseed oil and resin. Finally the whole is to be saponified to a neutral soap with caustic

potash lye. The completed mixture should show a 10 per cent content of rubber and from 5 to 10 per cent of palm oil. After immersion, the fabric is calendered by polished steel rolls under heavy pressure. Linen, hemp and cotton require heavier pressure than wool or silk. In this calendering operation care is needed to avoid such extreme pressure that the textile fibres are crushed. Casein is sometimes used in waterproofing certain textiles and collodion also, but rarely.

Absolute waterproofing of textile materials is obtained by applying to their surface a thin layer of rubber. The first experiments were made in France by Besson in 1793; they were improved upon and perfected successively by Mackintosh and Hancock of Glasgow, Scotland, by Buttire and Guibal in France and by Goodyear in the United States. As in the case of Macadam with road surfaces, the successful efforts of Mackintosh perpetuated his name in connection with india rubber waterproof garments. The material is prepared by spreading on the surface a semi-liquid layer of rubber dissolved in benzol then submitting it to the action of heat to evaporate the solvent. Carbon disulphide first employed to dissolve the rubber, was replaced by a mixture of benzol or coal naphtha and essence of turpentine and later by benzol which alone is now used. In the treatment of cotton and linen cloth a small proportion of sulphur is generally added. A thin layer of this rubber solution is spread on the fabric by special machinery, after which the cloth is doubled, pressed and finished in calendars, the waterproof layer being thus in the centre of the finished material. (See RUBBER MANUFACTURES.) The offensive odor of waterproofed rubber garments may be remedied by treating them with aromatized vapors or by dipping them in concentrated infusions of vervain root, of orris root, of lavender, of camomile, etc. Ammoniacal vapor and sulphurous acid can also be successfully utilized to relieve rubbered materials of their penetrating odor. The application of rubber is made on dyed material in thread or in piece. The use of paraffine as an impervious agent allows the tissue to be dyed after being waterproofed. Paraffined tissues do not absorb water, which assumes a spheroidal shape and slides off the surface. The chief objection to paraffine lies in the fact that it is exceedingly brittle at low temperatures and melts readily with ordinary summer heat. Woolen tissues well cleaned by passing through a light and tepid bath of carbonate of soda and soap, are dried, then steeped in a solution of paraffine in petroleum ether, 60 or 100 grammes to the quart. They are afterward passed through roller pressers, dried in the open air, and sent to the dyeing vats.

As already pointed out waterproof rubbered textiles are not only impervious to water, but also to air and numerous other methods and processes have been introduced to produce fabrics which, while resisting rain, do not altogether obstruct ventilation. The consecutive dipping of cloths, as already explained, in soap and alum solutions or in gelatine and gall solutions or in a solution of acetate of lead and then in a solution of alumina, are resorted to with more or less success. Algin, obtained from seaweed, has been strongly recommended for the same purpose. One of the most modern processes consists in treating the fibres in the solution before they are manufactured into textiles and the fabric thus produced, while rain-resisting, offers the same ventilation as ordinary materials. «Fibre-mail,» as it is called commercially, is described as a clear, colorless substance held in solution for the purpose of treating silks, woolens, cottons, feathers, paper and other materials, so as to render them water-repellent and proof against dampness, mildew and moths. The value of the process is further stated to be by no means limited to the water-repellent qualities given to the goods treated. The application of the solution leaves a coating upon each separate fibre which, by the action of heat, is cured or vulcanized upon and into the fibre, strengthening it and leaving it impervious and elastic. Among other advantages cited are the properties of giving weight and body to the finer textile fabrics, and by this means, where desirable, economizing material, the quality of the goods being greatly improved and never deteriorated; the process also gives lustre and finish to fabrics, being especially valuable for silks, alpacas, etc.; gives elasticity and toughness to the fibres, preventing cracking and breaking qualities valuable for felt hats, silks, etc.; deepens and fastens the colors in dyed goods; resists stains and spots in the lighter and more delicate goods; prevents woods from swelling and warping; preserves painted surfaces; and prevents polished or metal surfaces from rusting.

Leather.—«Fibre-mail» is also successfully applied to leather and leather goods. Many compositions, some of them patented, have been long employed, for rendering leather waterproof by filling up the minute pores. Four or five may be briefly described as examples of the whole. Boiled linseed oil, mutton-suet, yellow-beeswax, and common resin are melted together over a slow fire and applied while hot to the leather, which is itself to be made warm. Linseed oil, resin, white vitriol spirit of turpentine and white oak sawdust are the materials of another composition. Yellow beeswax, Burgundy pitch, turpentine and linseed oil constitute a third. A fourth plan consists in applying to the leather a hot mixture of two parts tallow with one part resin. Another is to first apply a coating of tallow to the leather with a second coating of one part copaiba balsam with two of naphtha. Caoutchouc, boiled for two hours in linseed or neat's-foot oil is also said to be effective.

Structures.— Paint and silica compounds, oils, varnishes and gums have long been experimented with for the preservation of buildings by waterproofing. The Sylvester process has long been in vogue for stone, brick and cement surfaces. It consists of alternately applying hot washes of soap and alum. Coating buildings with linseed oil has been a favorite method as affording some degree of protection against the deteriorating action of the elements. But linseed oil alone or mixed with colors, varnishes and gums has never proved wholly efficient to prevent the disintegration of stone, the weather staining of brickwork, the crumbling of mortar joints and the efflorescence of soluble salts, contained to a greater or less

degree in all bricks, cement and some varieties of stone; this is owing to the protective materials in themselves being subject both to chemical changes when exposed for a comparatively short time to the weather. When linseed oil alone is used, should there be any lime or alkaline salts in the wall, these immediately saponify the oil and render it useless as waterproofing. The oil soon dries out and leaves a spotted or mottled surface. Paint is often seen peeling off from the mortar joints of a building and from the brick work as well, owing to the same cause, the caustic alkaline properties of the salts of lime saponifying the linseed oil in the paint. Among scores of proprietary secret formulas there are some that are indisputably good and are thoroughly guaranteed by their makers. It is the custom of some architects to call for these applications in specifications.

Dry foundations are necessary in order to prevent moisture from rising by capillary attraction from the damp earth into the bases of walls or stoops. One or more perfectly waterproof courses near the foundations and reaching above the level of the ground, should be introduced as a «sine qua non» to a good building. Otherwise, a constant state of dampness, affecting that part of the structure, is apt to produce staining and disintegration beyond redemption. Cement or slate will not effectually answer this purpose owing to their absorbent qualities. Asphalt, sheet lead, copper or some other non-absorbent material should be used. The modern practice of builders of valuable structures is to construct a waterproof «membrane» completely enclosing the foundation. This is commonly a succession of layers of burlaps cemented together with asphalt and united to the foundation material by the same impervious substance. An elastic felt recently introduced is claimed to be superior to the burlaps. Sheet lead as foundation waterproofing is found in the ruins of Roman buildings 2,000 years old. One of the best processes hitherto employed for waterproofing the exterior and interior surfaces of the walls, is the paraffine compound process. The base of this compound is paraffine wax of special manufacture with refined creosote oil and other substances not disclosed. The method of application is to warm the wall to be treated, to the depth of about one-quarter of an inch, thereby evaporating all moisture and rendering it absorbent of the waxy material. The melted waterproofing is then applied to the warm surface until absorbed into the pores. It there remains for a brief time in a liquid state, penetrating as deeply as the surface is heated and dry and gradually hardens as the surface cools. The pores are thus permanently filled and rendered solid without altering the appearance of the stone, etc., treated. This waterproofing compound thus forced in by heat and becoming solid when cold, is far more durable and effective than superficial applications of cold solutions, oils or paints, applied in the usual manner, which do not penetrate into the material, which soon perish, if they are not previously chipped or rubbed off.

As a preservative of stone and marble, of monuments and statuary, vaults, etc., from the destructive effects of the weather so often observed in cemeteries, the process has proved of great value.

A material successfully used in Europe is a fluo-silicate of magnesia, commercially known as «fluate.» Its application both hardens and rainproofs stone, but it takes a year to demonstrate the effect. Consult Ross, J., 'Waterproofing Engineering for Engineers, Architects, Builders, Roofers and Waterproofers' (1919).

WATERS, Territorial. See INTERNATIONAL LAW.

WATERS, Underground. A certain amount of the water that falls on the earth's surface passes underground, the percentage varying with the porosity of the surface materials. This absorption of water is due to the fact that all rocks are somewhat porous and considerably fissured. Sand and gravel deposits are very porous and can store from 15 to 35 per cent of their bulk of water. Sandstones have space between their sand grains, but their porosity varies greatly with size of grain and especially with the amount of cementing material filling the interspaces which, in the case of quartzite and some highly calcareous sandstone, fill these spaces entirely. Most sandstones, however, are porous and many hold from 5 to 10 per cent of their bulk of water. Limestones are only slightly porous, but they are always traversed by joint planes and usually, toward the surface, by channels and caverns. Clays, shales and slates have but little capacity for water and the crystalline rocks, such as granite, have very slight porosity. Crystalline rocks, however, are usually traversed by many joint planes and often by zones of decomposition along which surface waters descend for a greater or less distance. In many districts, also, the crystalline rocks are deeply decomposed by the solution of some of their components, and the resulting «rotten rock» is usually as porous as many sandstones. Many lavas are porous and they usually are extensively fissured. Water passes underground in various ways, of which the following are the most prominent: direct inhibition of rainfall; the sinking of surface flows in passing over zones of porous rock; the spreading of streams laterally into the porous deposits of their valleys; and the percolation of water laterally from the ocean or lakes into the materials of the shore. In all regions it is found that the surface run-off and evaporation do not equal the rainfall, which is evidence of the general inhibition of water. Many streams are observed to diminish in volume and even to disappear entirely in running over areas of porous sandstones, cavernous limestones or especially permeable portions of their beds. In many arid regions waters flow out of the mountains in rocky beds and at once sink in the sands of the valleys. In nearly all river valleys there are

alluvial deposits in which the water extends laterally from the main stream and some watercourses have water only in the sands and gravels of their beds for the greater part of the year.

travel of underground water is slow, averaging about one mile a year in moderately porous sandstone.

In the accompanying figures are shown some conditions of underground waters, which have

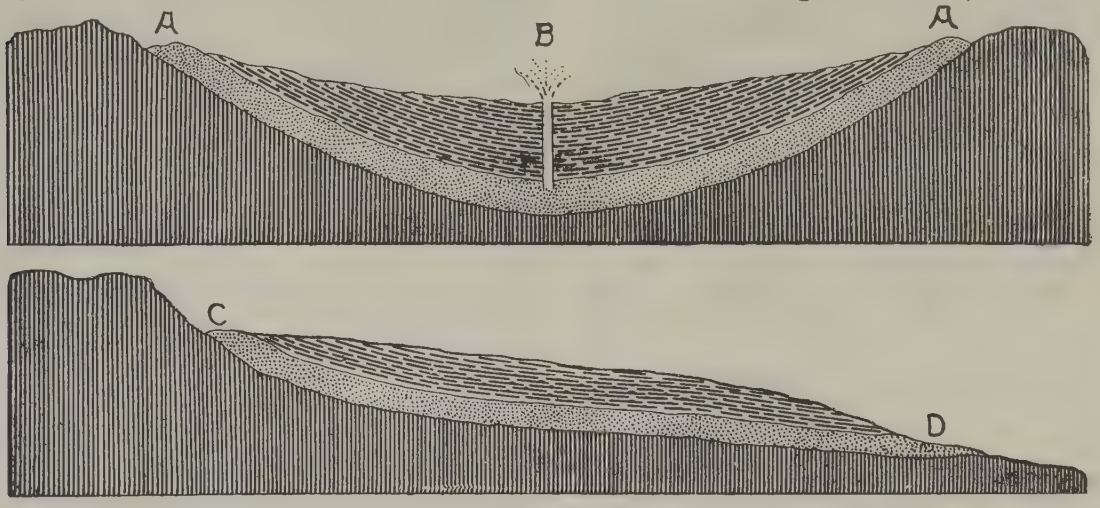

Fig. 1.

Waters present various conditions underground, in some cases flowing to lower levels, through permeable rocks, caverns in limestone or crevices in the harder rocks, to emerge as springs in hillsides, valley bottoms or even out under the ocean, as off the east coast of Florida. Usually the water supply fills an underground reservoir of sand, gravel, porous sandstone, decomposed crystalline rock or fissures. Water under this condition is usually designated "ground water" and its surface level is known as the "water plane." In some cases ground water may occupy strata or follow down crevices for a depth of several hundred feet. Waters which extend far underground are mainly contained in sandstones, and some of these water-bearers are of vast extent and often descend to great depths. Two conditions frequently existing are shown in accompanying cuts. Fig. 1. Cross-sections showing conditions of underground water in permeable rocks. In the first of these sections a bed of sandstones reaches the surface at *A A* where it receives water from rainfall or sinking of streams. This water passes underground below relatively impermeable clay or shale, and an artesian basin is formed which would yield a flowing well at *B* and at other points where the land is less elevated than at *A* and *A*. In the second section the conditions are somewhat similar, the water entering at *C* but escaping in springs at *D*, so there is a constant flow from *C* toward *D*. On account of this flow to a lower level there is gradual diminution of "head" of the water from *C* to *D*, known as the "hydraulic grade." This condition is found in the Central Great Plains of the United States, where there is a bed of porous sandstone with an average thickness of 200 feet, underlying more than 500,000 square miles and in places lying 5,000 feet deep, and apparently filled with water throughout. Many wells draw artesian supplies from this sandstone and in some areas the flows have a surface pressure of over 200 pounds to the square inch. Hundreds of billions of gallons are contained in this stratum. The rate of

been referred to above. Fig. 2. Sections of a river valley, showing the relations of underground waters. This valley is cut in rock but partly filled with sand and gravel, as shown by

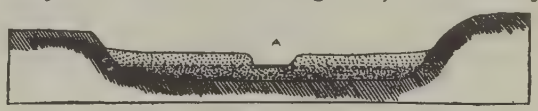

Fig. 2.

the stipple. The river flows on the surface at *A* but the waters also flow slowly underground in an "underflow" and pass laterally into the sands, filling them to the "water plane" *B B* at the level of the river. Fig. 3. Fissured and de-

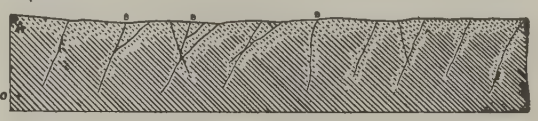

Fig. 3.

composed crystalline rock. Surface waters often sink deeply and occur in considerable volume under the conditions shown in this figure. *A* is the zone of decomposition and disintegration of the rock. *B B* are fissures down which the decomposition has progressed still deeper. This condition is found over wide areas in the Piedmont region of the eastern United States.

WATERSHED. See Rivers.

WATERSPOUT, a meteorological phenomenon frequently observed at sea, and analogous to the whirlwinds experienced on land. It occurs when opposite winds of different temperatures meet in the upper atmosphere, whereby a great amount of vapor is condensed into a thick black cloud, to which a vortical motion is given. This vortical motion causes it to take the form of a vast funnel, which appears to descend near the surface of the sea, creates

a partial vacuum at the center and draws up the water in its vortex, which joins in its whirling motion. The dark cloud above does not in fact descend, as is usually stated by observers, the column being formed by the visible condensation of the moisture in the rapidly ascending air currents. The whole column, which after the junction extends from the sea to the clouds, makes a magnificent appearance. It is light in color near its axis, but dark along the sides. When acted on by the wind the column assumes a position oblique to the horizon, but in calm weather it maintains its vertical position and is carried along the surface of the sea. Waterspouts seldom last more than a few minutes and are not as a rule dangerous to passing vessels. Firing a projectile into one to dissipate it has not been observed to give any appreciable results.

WATERTON, wô'tĕr-t'n, **Charles,** English naturalist: b. Walton Hall, Wakefield, June 3, 1782; d. there, May 27, 1865. He was educated at the Roman Catholic College at Stonyhurst, where he showed a great taste for natural history. He spent many years in travel, and in 1825 published *Wanderings in South America, the Northwest of the United States, and the Antilles in the years 1812, 1816, 1820, and 1824,* a book which attained great popularity. An illustrated and slightly altered edition was published under the direction of J. G. Wood in 1879. His only other publication is *Essays in Natural History, with an Autobiography.* These appeared originally in three series (1838, 1844, 1857). In 1870 Norman Moore produced a new edition of them, together with some of his letters and a life. He lived a secluded life for many years at Walton Hall, where he formed a curious collection of animals.

WATERTON-GLACIER INTERNATIONAL PEACE PARK, established in 1932 by acts of the Canadian Parliament and the United States Congress, comprises Waterton Lakes National Park in southwestern Alberta and Glacier National Park in northwestern Montana. The largest of the Waterton Lakes, 11 miles long, straddles the international line at an elevation of 4,193 feet.

WATERTOWN, wô'tĕr-town, town, Connecticut, Litchfield County, altitude 600 feet, is located on the Naugatuck River, 6 miles northwest of Waterbury, on the New York, New Haven and Hartford Railroad. Its industrial products are silk and rayon goods, plastics, wire products, pins, and tacks. The Taft School for boys is here. The town was set off from Waterbury in 1780. Pop. (1950) 10,699.

WATERTOWN, town, Massachusetts, Middlesex County, altitude 20 feet, is located on the Charles River, 6 miles west of Boston, on the Boston and Maine Railroad. It contains the villages of Bemis, Watertown, and Mount Auburn, and was first incorporated in 1630. It has a number of industries, chief of which are manufactures of rubber footwear, tires, rubberized and waterproofed cloth, elevating trucks, shoe findings, food products, textile machinery, paint, varnish, stoves, and heating apparatus. A large amount of modern ordnance is produced at the United States arsenal here. Perkins Institute for the blind is here; also the famous Mount Auburn cemetery. Pop. (1950) 37,329.

WATERTOWN, city, New York, Jefferson County seat, altitude 478 feet, is located on the Black River, about 10 miles from its entrance to Black River Bay, an arm of Lake Ontario, about 70 miles north of Syracuse, on the New York Central Railroad. The area inside the city limits is 8.7 square miles.

Industries.—The city lies on both sides of the river, which has a fall of 112 feet inside the city limits. It takes its name from the fine water power, which has been used for manufacturing since 1802. From Carthage, a village 16 miles above the city, to Dexter, eight miles below the city, the river is lined with busy manufacturing villages, which contribute to a considerable extent to the prosperity of Watertown. Along this 24 miles of river valley is a string of paper mills, and there is a considerable output of paper-making machinery. Next in importance to the paper industry is the manufacture of railway airbrakes. The other major factory products are metal working, clothing (women's dresses and knit goods), clinical thermometers and optical goods, flour and other grist mill products (including dietetic foods), plumbers supplies, mattresses, and electrical machinery.

Trade and Finance.—Watertown is the financial and commercial center of the largest dairy farming section of New York State, as well as one of the greatest resort sections, the Thousand Islands region. To the east are the Adirondack Mountains. It is also an important wholesale and distributing center for the northern section of the state with its rich farms and dairies—but scattered population.

It was in Watertown stores that Frank W. Woolworth, brought up in Great Bend, a few miles to the east, clerked in stores in the 1870's before he set up his first five-and-ten-cent store in Utica. There is a large Woolworth Building in the city. Watertown is an important insurance center with the home offices of two companies.

Buildings and Municipal Improvements.—The retail business of the city is located in Public Square, an imposing plaza situated in the geographical center of the community, and on thoroughfares that radiate from the common center. The public buildings include the post office and federal court building, a state armory, county buildings, the city hall, the Jefferson County Historical Museum, and the Roswell P. Flower Memorial Library, a classic marble structure, the gift to the city by Mrs. Emma Flower Taylor as a memorial to her father, Democratic governor of the State of New York in 1892–1895 and a leading citizen of Watertown. The city also has two orphanages and four hospitals. The Henry Keep Home, established and endowed by Mrs. Emma Keep Schley, is a refuge for the aged. There are two schools for graduate nurses. Of Watertown's numerous churches, the largest and most attractive are Trinity Episcopal, erected by the late Roswell P. Flower and his brother, the late Anson R. Flower; the Sacred Heart and Holy Family (Catholic); the First Presbyterian; Emmanuel Congregational; and the Asbury Methodist. The Young Men's Christian Association, a six-story building, and the Young Women's Christian Association, occupying its own building, are both located in Public Square. The Black River Valley Club,

with a modern clubhouse in lower Washington Street; the Elks' Club; the Masonic Club, housed in a beautiful marble temple; the Knights of Columbus, with a spacious club home in Stone Street, close to the business center; and the Lincoln League, with about 2,000 members, are the principal social organizations of the city. Watertown is overlooked on the east and south by Thompson Park, purchased, developed and presented to the city by the late John C. Thompson. A number of playgrounds (tennis courts and baseball diamonds) are maintained by the city. Watertown has one daily newspaper. The city owns a municipal airport, a hydroelectric power plant (1927) and its street-lighting system.

History and Government.—Watertown was settled about 1800 by five New Englanders who had pushed their way up from the Mohawk Valley, finally stopping at Black River Falls, and naming the site appropriately, Watertown. Their sawmills and gristmills, which they built along the Black River, attracted the settlers of nearby hamlets, who came to find work in the carpenter and machine shops. Papermaking began with the introduction of a rag mill in 1809. For a time the settlement was less important than Sackett's Harbor, 10 miles to the west, a fine port on Lake Ontario and a strategic point in the War of 1812. But the water power of the Black River helped Watertown's industrial growth. On Jan. 1, 1920 the city adopted the commission-manager plan of government with a city manager and a nonpartisan commission of five members. Pop. (1890) 14,725; (1900) 21,696; (1910) 26,730; (1920) 31,285; (1930) 32,205; (1940) 33,385; (1950) 34,350.

WATERTOWN, city, South Dakota, and Codington County seat, altitude 1,733 feet, is located on the Big Sioux River, 90 miles northwest of Sioux Falls, on the Chicago and North Western; Chicago, Rock Island and Pacific; Great Northern; and Minneapolis and St. Louis railroads; has an airport, with airline service. Situated in an agricultural and stock-raising region, it is a railroad and shipping center, and has varied industrial interests. The processing and packing of foods constitute a prominent item in the industrial schedule; meat and poultry are shipped. There are creameries, flour mills, machine works, and bottling works; and cement and concrete, sashes and doors, are made. There is an extensive wholesale trade in farm machinery and tools, feeds and seeds. Several large chick hatcheries are located in the immediate vicinity. In the near-by district are extensive, developed deposits of sand and gravel. Watertown has a Carnegie library, a standard public school system, parochial schools, and excellent recreational facilities in the city parks and at Lake Kampeska, to the west. The lake, covering approximately 12 square miles, is a summer resort, with casino, clubhouses, and a municipal golf course. Public buildings are the courthouse, the city hall, the post office, and an auditorium. The city owns an electric plant and the water works. It was platted in 1878 and incorporated in 1885. In 1913 it adopted commission government, but in 1916 it returned to the aldermanic form. Pop. (1950) 12,699.

WATERTOWN, city, Wisconsin, in Jefferson and Dodge counties, altitude 824 feet, on the Rock River, and on the Chicago, Milwaukee, Saint Paul and Pacific and the Chicago and North Western railroads, 44 miles northwest of Milwaukee and 38 miles northeast of Madison, the capital of the state. It is on both sides of the river, and has considerable water power which is utilized by various manufacturing plants, chief of which are large shoe factories, flour mills, foundry and machine shops, creameries, and factories producing dairy products and equipment, furniture, wood table slides, automatic cashiers and sorters, carbonated beverages, dresses, rubber products, snow plows, paper boxes, store fixtures, apiary equipment, Venetian blinds, airplane propellers, cutlery and garden tools, ice cream, condensed milk, canned vegetables, stuffed geese, heating equipment, rope halter, interior finish, and concrete vaults. The city is a shipping point for butter and cheese and is noted as a goose market. Northwestern College (Lutheran, 1865), and Sacred Heart College (Roman Catholic, 1872) are here. Bethesda Lutheran Home (for the feeble-minded) is here.

The place was first settled in 1836 by Timothy Johnson and other settlers from Watertown, N. Y. It was incorporated as a village in 1849 and chartered as a city in 1853. Many Germans settled here about 1848, and in 1856 Carl Schurz (q.v.) came to Watertown, where he soon became a leader in the Republican party. His wife, who had been a pupil of Friedrich Froebel (q.v.) established in Watertown one of the first kindergartens in America. The municipal government is by city manager and five aldermen elected at large. Pop. (1950) 12,417.

WATERVILLE, city, Maine, Kennebec County, altitude 100 feet, is located on the west bank of the Kennebec River (opposite Winslow), 19 miles north of Augusta, on the Maine Central Railroad. It has a municipal airport. The Ticonic Falls furnish water power for industries here and in Winslow, and the Maine Central Railroad has repair shops here. The chief manufactured products are paper and pulp, cotton and woolen goods, men's shirts, lumber, wood products, fiber dishes, ice cream, shoddy, signs, and tractors.

Waterville is the site of Colby College (Baptist, coeducational) founded in 1818 and called Waterville College until 1867; and of Coburn Classical Institute. Samuel F. Smith (q.v.), who wrote the verses of the national anthem, *America,* lived here 1833–1842. The region was called Teconnet by the Indians. It was settled about 1760 by emigrants from Cape Cod, and was part of Winslow until 1802 when it was set off as a town and incorporated under the name of Waterville. In 1873 it was separated from West Waterville, and was incorporated as a city in 1883, receiving its charter in 1888. Government is by mayor and council. Pop. (1950) 18,287.

WATERVILLE, village, New York, Oneida County, altitude 1,231 feet, is located 21 miles southwest of Utica, on the Delaware, Lackawanna and Western Railroad, in an agricultural region in which hops and vegetables are the chief products. Picking peas and beans for the canneries is a seasonal occupation in the locality. The first settlers came from Waterville, Me.,

shortly before 1880. George Eastman (q.v.), inventor and philanthropist was born here. Pop. (1950) 1,634.

WATERVILLE, village, Ohio, Lucas County, altitude 654 feet, is located on the Maumee River, 14 miles southwest of Toledo, on the New York, Chicago and St. Louis Railroad. It is the trading center for an area of extensive plant nurseries, and each year in May holds a blossom festival. There are limestone quarries, oil and gas wells in the area. Glass, metal, rubber, and food products are manufactures. Here along the old Miami and Erie Canal is Waterville State Park, and along the river are numerous other public parks. In this region, in 1794, the forces of Mad Anthony Wayne (q.v.) battled with the Indian tribes. Pop. (1950) 1,110.

WATERVLIET, wô'tĕr-vlēt, city, New York, Albany County, altitude 27 feet, is located on the Hudson River, opposite Troy, 6 miles north of Albany, on the Delaware and Hudson Railroad. It is an industrial city producing coated abrasive and sharpening stones; hair brushes and other toilet brushes; steel castings and ingots; gray iron castings and bronze, and aluminum castings; harness; hardware; wooden ladders and scaffolding; silk, wool, rayon, and nylon yarns.

The United States Arsenal established here in 1813 has been a major factor in the industrial history of the city. It made guns for the War of 1812. Until 1887 it manufactured army equipment and shells. Since then it has supplied guns for every war in which the United States has participated. It has 30 buildings, including residences for officers, and is equipped to build heavy ordnance and rapid-fire antiaircraft guns. Its peak employment in World War II was 7,334 persons.

Watervliet was settled about the time the first settlements were made at Albany (1623). Overlooking the Hudson River is the Schuyler Homestead, only slightly altered since its erection in 1666. In 1774 Mother Ann Lee, founder of the Shakers (q.v.), arrived in America from England with a small group of converts and settled in Watervliet in 1776. Later, in 1785, they established a colony at Mount Lebanon, near the New York-Massachusetts boundary. Watervliet was incorporated as the village of West Troy in 1836. In 1897 it was chartered as a city under its present name. Government is administered by a city manager. Pop. (1950) 15,197.

WATERWAYS OF THE UNITED STATES. This article discusses American waterways primarily from the viewpoint of waterborne commerce and navigation in their descriptive and economic aspects. Technical engineering discussions are avoided, being covered in other articles to which reference is made. By "waterways" are understood all channels carrying, or capable of carrying, commerce. The subject therefore is divided into three main parts: (1) inland waterways, including rivers, canals and intracoastal waterways; (2) the Great Lakes system; (3) seaports and harbors.

INLAND WATERWAYS

Agencies and Means of Improvement.—Practically all waterways of the United States actually or potentially navigable are, by the Interstate Commerce clause of the Constitution, under jurisdiction of the federal government as regards navigation. This does not mean that the government owns in fee simple the waterways or the land under or adjacent to them, but that in so far as concerns matters affecting navigation it exercises a dominant control over any structures or activities on the waterways. Accordingly, improvements of natural channels for the benefit of navigation, other than such purely local matters as the dredging of slips or of approaches to terminals, have throughout our history been carried on mainly by federal agencies. This statement does not however apply to purely artificial waterways, that is, canals; the government has constructed a few, of which the most important is, of course, the Panama Canal, but most canals have been built by states or other public or private interests. See also article on CANALS.

The agency of the federal government for the creation and maintenance of navigable channels is the secretary of war, and under him the chief of engineers and corps of engineers of the army. This river and harbor activity of the army engineers is in addition to their purely military duties, and officers alternate between the two forms of work. Field work is handled in ten division offices by 47 territorial districts, which cover the entire United States, with offices at principal cities, and by special agencies such as the Mississippi River Commission and the California Debris Commission.

Every individual project for the improvement of a navigable channel must be authorized as a law by Congress. The usual procedure to obtain an improvement, or the extension of an existing improvement, is first for Congress, at the intercession of local interests, to direct the examination and survey of the channel. This is done by the army engineers who then recommend for or against the improvement. If Congress adopts their favorable recommendation the project becomes a law. It is then executed with the funds annually granted for river and harbor work, which, for the fiscal year 1952–1953, including funds for flood control, amounted to $584,000,000.

Congress has of course entire authority to order any improvement contrary to, or in the absence of, recommendation by the chief of engineers. Formerly this was often done, and resulted on occasion in the adoption of small and purely local improvements which gave rise to the term "Pork-Barrel." This practice has however practically disappeared. In recent years, and apart from emergency construction projects, practically no commercial waterway projects adopted have been ordered by Congress in the absence of a specific favorable recommendation by the chief of engineers.

The methods of improving inland waterways, and the details of plant and structures employed, are considered under articles DREDGE, CANALS, RIVER ENGINEERING, and HYDRAULIC ENGINEERING. Briefly, they fall into the two classes of canalization and open-channel work. Canalization consists of providing a navigable channel in a river by a series of dams creating long deep pools, each dam having one or more locks through which vessels pass from one pool to the next. In a river such as the Ohio, subject to very great rises of water in

floods, the dams are often arranged so that at high water they can be lowered or otherwise manipulated when lowered, commerce then passes down the main river over the lowered dams instead of using the locks.

Open channel improvement includes all methods other than canalization. Most rivers, even when canalized, also require at certain points some open channel work. The principal methods are *dredging, snagging* and *regulation. Dredging* of course consists of the removal of material from the bottom to form a sufficiently deep channel. See DREDGE. This may of course involve rock excavation by blasting or other means. *Snagging* is the pulling out and safe disposal of trees or logs which lodge in the river with one end at or near the surface, and are a menace to passing boats. It is required continually on some large rivers, such as the Mississippi, and on many small rivers is the only form of improvement done. *Regulation* consists of so manipulating the flow of the river as to hold the river at the point desired and force it to dig a deep channel for itself. The usual means is the construction of dikes or wing dams projecting into the river from the sides, or sometimes built parallel to the channel, thus constricting the flow and producing scour of the bottom and a deeper channel. A form of river regulation is the construction of levees and the paving and revetment of banks designed to hold the river, even during floods, in its main channel and to prevent it overflowing and eroding the banks. This is extensively practiced on the Mississippi. See MISSISSIPPI RIVER.

B. Channel Depths.—The most important element of a navigable channel is its depth. American improved internal waterways have a variety of depths, dictated partly by the type of traffic for which they are designed and partly by the amount of money which it is appropriate to spend on them. Broadly speaking, we may say that modern internal navigation practice in this country tends to one of four standard depths: (1) 12 feet, appropriate to large barges and river steamers. This is the depth of the New York State Barge Canal now being deepened to 14 feet and the upper Hudson, and is about the depth of small waterways on or connected with the Hudson which have commercial relations with it. It has also been the depth of the canal connecting Chesapeake and Delaware bays now being deepened to 27 feet and of the intracoastal waterway from Norfolk to the Cape Fear River, N. C. (2) 9 feet, appropriate for large river steamers of the type used on the Western rivers, and for good sized barges, up to 2,000 tons capacity, handled by river tow-boats. This is the project depth of the Mississippi to St. Paul, of the Ohio and Illinois and of the intracoastal waterway from New Orleans to Corpus Christi. It may be called the maximum depth of the Mississippi system. (3) 6 to 9 feet, appropriate to medium barge traffic and large motor-boat or small steamboat traffic. These are the project depths of some of the South Atlantic intracoastal waterways, and of the Missouri River to Sioux City. (4) 4 feet or less. Appropriate to small motor boats, small barge traffic and the floating of logs. Such depths obtain in small Southern and Southeastern rivers. The Lakes traffic is of course of a different sort, but excluding the Lakes, channels over 12 feet in depth are in practically all cases port or harbor channels serving ocean-going vessels.

Throughout this article, depths for tidal waterways along the Atlantic and Gulf coasts refer to mean low water; tidal waterways along the Pacific coast to mean lower low water; and non-tidal rivers generally to low water, or ordinary summer low water.

C. Principal Inland Waterways—Location and Description of Channels.—Full details of the project dimensions of all channels under improvement by the United States, of their condition, cost and the present activity on them may be found in the annual reports of the Chief of Engineers. Of some 300 internal waterways now under active improvement only the most important will be referred to below.

From the viewpoint of commerce, the waterways fall into ten clearly defined geographical groups.

1. The New England Rivers.—These are usually small, the Connecticut and several Maine rivers being exceptions, and in nearly all cases the fall line is near the sea. Their commercial importance is therefore generally limited to short stretches near the mouth which have been in many cases improved to a depth suitable for ocean going vessels. Such channels are properly approaches to *ports* and will be considered under that head. The Connecticut, though a large and long river, presents considerable difficulties to improvement above Hartford, and has never been fully developed. The Susquehanna in Pennslyvania belongs to the same class, as does the Delaware above Trenton.

2. Hudson System.—The Hudson River is the finest natural waterway in the country. For 117 miles, up to Hudson, it is really a natural tidal estuary capable of carrying ocean vessels. General improvements near the mouth are part of New York Harbor. A project now substantially completed provides a 27-foot channel to the city of Albany, making the latter an ocean port. Above Albany there is a completed 12-foot project to Troy with a lock and dam at that point. Thence the river connects with the New York State Barge Canal, completed in 1918 by the state of New York at a cost of over $150,000,000, a portion of which is now being deepened to 14 feet. This, the most ambitious waterway project ever undertaken by an individual State, is a successor of the old Erie Canal, which was so important a factor in the early and middle 19th century in opening up the Middle West and in placing New York City in the position which it has never lost, of the leading city and seaport of the country. The present Barge Canal (q.v.) has a governing depth of 12 feet, and in the canal sections, as distinguished from river sections, a bottom width of 75 feet. The main line extends from Troy to Tonawanda, on Niagara River, thus giving connection with Lake Erie. A branch extends to Oswego and connects with Lake Ontario and there are minor branches in the Mohawk Valley. Connected with this system is the Champlain Canal, also built by the State of New York, from Troy to the southern end of Lake Champlain. A 12-foot channel through the narrows of that lake, furnished by the Federal Government, gives navigation facilities into the deep part of the lake and there are Federally improved harbors including Burlington and Port Henry. This system tics the Atlantic coast, by

a good barge channel, to the entire Great Lakes territory and to northern and central New York.

3. The Southeastern Rivers.—This is a group in the territory from Virginia to Mississippi, which have many common characteristics. They rise in the Appalachians and flow first through the Piedmont district, which is generally a rich agricultural territory with rapidly developing industries. Near their fall line they enter the coastal belt, a flat and often swampy area with formerly a heavy growth of timber, and flow thence to the sea. In this lower stretch they are, or can at very little expense be made, navigable to depths up to from 4 to 6 feet or more. This coastal belt is not however densely populated, and with the cutting out of the timber, the potential resources for water transport have greatly decreased. A large potential commerce for the rivers exists in the Piedmont, but to reach it the rivers must in general be canalized, often at large expense. They are subject to floods which may cause a rise of 30 or 40 feet.

The following are the improvements of the principal rivers of this section (not all of which conform exactly to the above general description).[1] The Potomac is really a port approach up to Washington. The Rappahannock has a 12-foot project up to Fredericksburg, with a present controlling depth of about 10 feet. The York has good natural channels in the lower sections, and improvement has not thus far been found necessary. The James is a port approach to Richmond (See «PORTS» below). The Appomattox, a tributary of the James, has a channel to Petersburg about 10 feet deep, completed and maintained. The Roanoke has natural depths of at least 10 feet up to Hamilton, over which stretch snagging operations are carried on, and from Hamilton to Weldon there is a project for a 5-foot channel which is partly completed, the governing low water depth being 3 feet. The Pamlico and Tar Rivers in North Carolina have project depths of 12 feet to Washington, thence 6 feet to Greenville, thence 20 inches to Tarboro, with a provision for snagging and clearing up to Little Falls. A channel 11.5 feet deep exists to Washington, but depths less than 6 feet are at present found below Greenville. The Neuse has a project channel 12 feet deep at low water, to Newbern, thence 4 feet to Kinston and a lesser improvement to Smithfield, with project depths existing to Newbern and somewhat less above. The Cape Fear River to Wilmington, N. C., is a port approach. Above Wilmington there is a project for an 8-foot depth at low water to Fayetteville involving the construction of three locks and dams. These structures have been completed. The Savannah River is a port approach up to Savannah. Thence there is a project channel 6 feet deep at low water to Augusta, to be obtained by the construction of one lock and dam and by open channel work, work on the project now under way. A minor project exists above Augusta. The Altamaha River in Georgia has a project for a 3 to 4 foot channel at low water over the entire stretch of the river to its head at the junction of the Oconee and Ocmulgee Rivers, to be obtained as far as is possible by minor works. Such work is carried on as is of assistance and benefit to existing navigation. Turning to the Gulf rivers, the Apalachicola has a project channel 6 feet deep at low water, with a supplementary connecting 5-foot channel, which depths have been attained. A tidal canal 9 feet deep at mean low water connects this river from a point a little above the mouth with deep water at St. Andrews Bay to the west. The Chattahoochee has a 4-foot project up to Columbus, Ga., maintenance of which involves dredging, snagging and regulating; the full depth is available from January to August.

The most important, ambitious and successful purely river improvement in this stretch is that of the Mobile River system, including especially the Black Warrior. The latter stream passes through the great coal deposits of west central Alabama and close to the important steel centre of Birmingham. Commercially, therefore, it is at the present moment in a much more favorable position than the other rivers of this section. The approach of the Warrior is via the Mobile and lower Tombigbee Rivers, both of which below the mouth of the Warrior have natural or improved channels 9 feet deep. The Warrior River system has been improved for 476½ miles by a chain of 17 dams and 18 locks up to about the latitude of Birmingham, which takes it through a large part of the coal section.

4. The Florida Rivers.—These are of a different class from the other southeastern rivers, due to local topography. The St. Johns River somewhat resembles the Hudson, in that for a long distance it is a tidal estuary with excellent natural depths, capable of improvement at relatively small cost. Up to Jacksonville it is a port approach channel. Thence for 55 miles, to Palatka, it has an improved 13-foot channel; for 92 more miles, to Sanford, an improved 8-foot channel, and above Sanford a 5-foot channel to Lake Harney. The other principal system of the Florida peninsula centres on Lake Okeechobee, which, with the connecting rivers and the drainage canals recently dug by the State of Florida, form a system of light and medium draft channels centering on Okeechobee. In connection with the construction, now nearing completion, of levees about Lake Okeechobee to prevent overflow in times of hurricane storms, a channel of not less than 6 feet in depth is being made available entirely across southern Florida via St. Lucie River and canal, Lake Okeechobee and Caloosahatchee Rivers. Construction has also been inaugurated under the Emergency Relief program of a cross Florida ship canal via St. Johns, Oklawaha and Withlacoochee Rivers.

5. The Mississippi System.—This falls into three sub-systems:

(a) The Mississippi proper and its minor tributaries.

(b) The Ohio and its tributaries.

(c) The Missouri.

5-a. The Mississippi up to Baton Rouge is a port approach channel with depth of 35 feet. For much of the distance between Baton Rouge and Cairo there is a natural 9-foot channel. The river flows however in a very sinuous course through a broad flood plain composed of soft alluvial soil, and being subject to tremendous floods, tends continuously to erode its banks and shift its channel, with a corresponding

[1] Special descriptions are given only to rivers currently carrying in excess of 100,000 tons of commerce per annum.

temporary deterioration of that channel. The improvement for navigation therefore consists not only in dredging shoals, but also and largely in holding the river in place. This can be best attained by levees which contain the flood water of the river, coupled with revetments and other bank protection work which prevent the flood waters from attacking the banks at critical periods and undercutting the levees. Such work, by preventing the overflow of the river, is, of course, flood control as well as navigation work, and indeed the former aspect is at least as important as the latter.

The methods and achievements of the Army engineers in the past half century, in the tremendous task of controlling the Mississippi, are described under MISSISSIPPI RIVER, q.v. Briefly it may be said that they resulted in reclamation from periodic overflow of an area, extending along 1,571 miles of river, totalling around 27,000 square miles, larger than the State of West Virginia, the great majority of which is rich and valuable agricultural land. In 1922 the Mississippi was subject to one of the greatest floods in history. This flood passed without a break in the main-line levee system from Cairo to Poydras below New Orleans, a distance of nearly 1,000 miles, and the break at Poydras was because, due to limitations of funds, the levee had not been completed to the dimensions planned by the engineers of the Mississippi River Commission. The methods adopted proved entirely satisfactory up to the great flood of 1927 when the Mississippi levees gave way in numerous places with the result that 18,000 square miles were inundated, while 750,000 people were directly affected, about 600,000 being rendered homeless and destitute. The damage caused by this flood was estimated at $300,000,000. This disaster, the greatest in the history of the country, emphasized the fact that some better method of flood control be adopted before it can be said that all danger from Mississippi River floods is a thing of the past.

From Cairo up to St. Louis, the river changes its character, with a lesser flow and generally firm, high banks. Flood control ceases to be an important problem, but strictly navigation improvement becomes more difficult. The river at low water tends to be too wide and therefore too shallow. The project channel is 9 feet deep, to be attained by a combination of regulating works, which narrow the channel, and by dredging at critical points. A 9-foot channel exists up to St. Louis, but on occasions of low water it may be shoaled to less than this and have to be dredged out. Some periodic dredging will probably always be necessary, due to the large deposits of sediment following floods.

Above the mouth of the Missouri the river is much smaller. There is a project channel calling for a 9-foot depth to St. Paul-Minneapolis, involving 26 locks and dams with lock chambers in general 110 feet wide and 600 feet in length, one of which is located at a dam, privately constructed primarily for power purposes, at Keokuk. Work on this project is being actively prosecuted and is scheduled for completion during 1938. Above St. Paul-Minneapolis there are minor shallow-draft channel improvements. The Government has also constructed six reservoirs near the headwaters of the river to impound flood waters and regulate the flow below. These have had a very beneficial effect on navigation depts both above and below St. Paul, and computations indicate that these reservoirs can and do increase the low water stage at St. Paul.

The commercially important tributaries of the Mississippi, other than the Ohio and Missouri, are, first, the Illinois, which has a 9-foot channel to Lake Michigan, second, a group including the Yazoo, the Red, the Arkansas and others, principally in the southern part of the valley, which resemble on a smaller scale the Missouri, described below.

5-b. The Ohio is formed at Pittsburgh by the junction of the Allegheny and Monongahela, and is nearly 1,000 miles long. It is subject to tremendous floods which may raise the water surface 60 feet more at certain points. At low water in a natural condition it tends to be broad and shallow, with numerous bad bars. The same description applies in general to its principal tributaries, namely the Allegheny, the Monongahela, the Kanawha, the Big Sandy, the Kentucky, the Cumberland and the Tennessee.

The improvement of the Ohio forms with the Upper Mississippi, the most ambitious river project for navigation only, undertaken by the Federal Government. The Ohio has an immense potential commerce, as it flows through the steel, coal and general manufacturing centres of the Pittsburgh district, Ohio and West Virginia, and through important manufacturing, mining and agricultural areas below. The adopted project provides for a 9-foot channel from the mouth to Pittsburgh, by the construction of some 50 locks and dams, whereby the entire river has been canalized. The project started many years ago, has been completed resulting in a 9-foot navigation channel throughout the entire river.

The Monongahela and Allegheny are both canalized, with governing depths of 8 feet on the lower and important stretch of the former and 9 feet on the latter. The Kanawha River is being canalized for 9 feet for 90 miles above the mouth; the Little Kanawha, for a 4-foot depth for 48 miles; the Muskingum for a 5½-foot depth for 91 miles; the Kentucky for a 6-foot depth for 280 miles; the Green and Barren rivers, in Kentucky, to about 6 feet for nearly 200 miles. All these canalized projects, except the Kanawha and Allegheny, are completed and the locks and dams are being operated and maintained.

The Tennessee River, the largest tributary of the Ohio, has presented great difficulties to improvement on account of the fall line crossing the river in the neighborhood of Muscle Shoals in northern Alabama, producing a series of rock shallows and rapids. Work on the river has been carried on at various points and under various projects, with material commercial advantage, but until recently the great cost of a thoroughgoing improvement prevented its adoption. However, the steep slope and rapids at certain points which so interfere with navigation, possess at the same time great potentialities for electric power, particularly in view of the large low-water flow of the river and the possibility of increasing this through regulating reservoirs in the mountains. It is notably a river in which economic improvement for navigation must go hand in hand with the

development of electric power. Large scale improvement along this line began with the adoption during the World War of the great power development at Muscle Shoals, intended primarily in connection with a Government nitrate plant. The nationally known Wilson Dam was completed in 1927, and construction of a series of large dams, equipped with locks 110 feet wide and 600 feet in length, to secure a 9-foot channel 650 miles to Knoxville, Tenn., is now actively in progress. A large amount of potential water power will be available at the dams. This construction is being carried forward by the Tennessee Valley Authority.

At present 6-foot navigation exists from the mouth of the Tennessee to Wilson Dam and thence by its locks for a further distance of about 15 miles. Above that point work on the project for extending the channel to Chattanooga is in various stages of completion.

Wholesale development of the power of the Tennessee above Wilson Dam seems likely in the next generation. Under instructions from Congress the Army Engineers have completed an elaborate survey of the electrical resources and the possibility of their development in conjunction with navigation. It is likely that several million horsepower will ultimately be developed.

The most important remaining tributary of the Ohio system is the Cumberland. This has a project for a 6-foot channel by canalization up to Nashville, a distance of 192 miles, and for a 6-foot channel thence for over 300 miles by 18 additional locks and dams.

5-c. The Missouri was naturally navigable in a sense from its mouth to Fort Benton in Montana, a distance of 2,285 miles. It is characteristically a broad, rather shallow river, subject to very large floods and with a tendency to erode its banks and shift its channel like the lower Mississippi. It did not however possess in a natural state as good a low water channel. From the mouth to Kansas City, about 400 miles, there is a substantially completed 6-foot channel. From Kansas City to Sioux City the project provides for a 6-foot channel also, work on which is actively in progress. A large retention reservoir is being constructed at Ft. Peck, Mont., which will aid in flood control and also supplement the flow in the lower river during low water periods, it being expected that the regulated river flow will afford a channel 8 to 9 feet in depth from Sioux City to the mouth. Between Sioux City and Fort Benton there are Federal projects for snagging and clearing the river and for bank protection at critical points with a view to holding the channel in its present position.

6. The Intracoastal Waterways of the Atlantic. — By «intracoastal waterway» is meant a protected channel, usually of a depth for small vessels, running close to and generally parallel to the coast. Reference is often made to «an intracoastal waterway» from Boston to Miami or to Key West. The statement requires some interpretation. There does not exist a continuous intracoastal channel over this section, and should one be provided in accordance with one of several proposed plans, its character and commercial significance, and the amount of protection provided, would vary greatly in different sections.

Starting from Boston, private capital had provided a ship canal across the base of the Cape Cod peninsula with a depth of 25 feet. The canal was purchased by the United States in 1928 and is now being deepened to 32 feet. By using this, the waters north of Marthas Vineyard, Long Island Sound, and the improved channel through Hell Gate, vessels can proceed from Boston to New York Harbor by a safer and more protected route than that around Cape Cod in the open Atlantic. An important commerce moves over this stretch. The waters are however often quite rough, and the vessels utilizing them are mostly either ocean-going steamers or sailing ships, or large seagoing barges. This stretch can therefore hardly be classed among inland waterways. The next step is from New York Harbor across New Jersey to the Delaware River. A canal was constructed by private capital many years ago on this section, but its dimensions and therefore its commercial possibilities are limited, and this canal known as the Delaware and Raritan Canal is no longer in use. The Government has under consideration a proposal for a ship canal across New Jersey, an ambitious and expensive project. From Trenton on the Delaware there is a 25-foot channel to Philadelphia, and thence an ocean channel to the sea; and about 40 miles below Philadelphia the Delaware is connected with Chesapeake Bay by a formerly privately owned canal. This was taken over in 1919 by the United States and is being deepened to give a 27-foot sea level canal. Chesapeake Bay through its entire length is navigable for large vessels, and carries an important commerce; the numerous small communities on its shores are to a large extent dependent on it, and there are also heavy movements affecting Baltimore, Washington and Norfolk. This extends the intracoastal system to Norfolk. South of that point the coast is characteristically fringed with sandy islands locally called «sea islands» or «keys,» behind which is a stretch of marsh with winding tidal creeks. By straightening these and linking them together with short canals, an excellent sheltered waterway can be furnished at comparatively small cost. In this manner the United States has completed a protected inland passage to Miami, Fla., with depths ranging from 7 to 12 feet. An extension of the waterway south to Florida Bay, a distance of 63 miles, was recently authorized by Congress.

7. Intracoastal Waterways of the Gulf.— On isolated sections of the west Florida coast from Mobile Bay to Lake Pontchartrain, and along the Louisiana and Texas coast, there are natural systems of intracoastal waterways of much the same character as those described as existing on the South Atlantic coasts. In southern Louisiana this system is very intricate and extends far north into the State, on account of the existence of streams which are now or formerly were supplementary mouths of the Mississippi. The most important is the Atchafalaya, which flows from the Mississippi, near the mouth of the Red, south into the Gulf. These streams are locally known as bayous. Many of them have naturally excellent depths. Federal improvement in the past has been concerned chiefly with linking up natural waterways by limited and inexpensive work. The great and growing importance of the Gulf coast has however made necessary a more

thorough-going improvement, and Congress has recently adopted a project for a through 9-foot channel, utilizing as far as possible existing channels, from the Mississippi to Corpus Christi. This will be sea-level except that a lock is required to enter or leave the Mississippi. On account of the sea island formation, it is practicable to continue such a channel from Corpus Christi, to the mouth of the Rio Grande, should it be found economically desirable. East from New Orleans there is a connection by lock to Lake Pontchartrain, whence a sheltered barge route exists along the coast to Mobile Bay, and thence to the vicinity of Carabelle, Fla., the general depth being 9 feet at mean low water. Surveys are in progress along the west coast of Florida to determine the need and practicability of the Gulf Intracoastal Waterway southerly to the proposed Florida Cross-State ship canal and on to the mouth of Caloosahatchee River.

8. The Sacramento-San Joaquin System.—These two rivers between them drain the central valley of California between the Sierras and the coast range, uniting to flow into San Francisco Bay. Most of their drainage area is rich agricultural land. The Sacramento, in its original state, had a fairly good channel for a considerable distance. An unusual and interesting problem, however, rose here in the last century, due to large scale hydraulic gold mining in the upper valley. The process adopted involved the washing into the river of an immense amount of sediment, the total amounting to many hundred millions cubic yards. This sediment choked the river and its tributaries, with serious results to navigation and to the flood situation. Due to the absence of adequate local regulation, conditions became so acute that Congress was forced to step in, and in 1893 created a board of Army Engineers, known as the California Debris Commission. The Commission drew up and has since enforced a system of regulations which prevented further damage from hydraulic mining. It also prepared a plan for the complete protection of the Sacramento Valley from the disastrous floods to which it is sometimes subjected, involving an elaborate system of levees, dams, floodways and channel enlargement. The project was adopted on a co-operative basis by the United States, the State of California and local land owners. While desired primarily for flood control, the above work is of material benefit to navigation, and other work is also being carried on specifically for navigation improvement. The Sacramento is now navigable up to the city of Sacramento with a depth of 10 feet, with lesser depths above.

The San Joaquin also handles an important river commerce up to Stockton on a 30 foot channel.

9. The Columbia System.—From its mouth to Vancouver, Washington, and to Portland, Oregon, on the Willamette, the Columbia has a very fine deep channel suitable for large ships. This stretch is a port approach. The upper Columbia and the Snake are large rivers but are broken in many places by falls and rapids. From Vancouver to the mouth of the Snake, the Columbia is generally navigable for shallow draft vessels except at two points, the Dalles and Celilo Falls. At both points the Government has constructed lateral canals with locks, having available depths of 8 and 7 feet respectively. There is also a project for clearing the river above Celilo Falls, and for minor work with a view to providing a 5-foot channel over the lower 218 miles of the Snake up to Pittsburg Landing. A large scale navigation improvement for the upper Columbia and Snake rivers must however, as in the case of the Tennessee, be done in connection with water power developments. Millions of horsepower are available on these rivers. A combined power and navigation dam is being constructed on the Columbia River at Bonneville, about 42 miles east of Portland, which was completed in 1937 and permits the extension of deep draft navigation to the Dalles 80 miles above Portland. The lock in the Bonneville Dam measures 76 feet wide and 500 feet in length and has the highest single lift of any navigation lock in the world.

The Columbia in its lower reaches has improved tributaries which, although their channels are limited, and little money has been spent on them, carry, in some cases, a very large commerce, though this is principally floated logs. The most important is the Willamette above Portland, Oregon.

10. Other Pacific Rivers.—A group of small or moderate sized rivers enter the Pacific or Puget Sound in Washington, Oregon and northern California. Their fall line is very close to the ocean, and below this they tend to have quite shallow natural channels with bad bars. The most important commercially are the Siuslaw, Umpqua, Coquille, Coos and Yaquina Rivers in Oregon and the Snohomish and Skagit in Washington. These have been improved to depths appropriate for their character of commerce, which is principally floated logs.

D. Tonnage and Value of Existing Commerce.—That for the principal waterways appears in the following table: (For full details see the annual reports of the Chief of Engineers, United States Army).

COMMERCE OF UNITED STATES WATERWAYS, 1937

	Short tons
Atlantic Coast Rivers:	
Penobscot River, Me.	805,981
Herring River, Mass.	347,000
Pawtucket, R. I.	408,711
Thames River, Conn.	422,457
Connecticut River below Hartford, Conn.	1,232,636
Hudson River (Spuyten Duyvil to Waterford, N. Y.)	11,091,186
Mantua Creek, N. J.	327,699
Delaware River, Philadelphia to Trenton	3,696,251
Elk and Little Elk Rivers, Md.	775,361
Potomac River below Washington	2,449,622
York River, Va.	350,389
James River, Va.	2,242,335
St. Johns River (Palatka to Lake Harney, Fla.	469,301
Miami River, Fla.	476,139
Gulf Coast Rivers:	
Mobile River, Ala., tributaries	1,663,807
Black Warrior, Warrior, and Tombigbee Rivers, Ala.	1,825,568
Bayou Teche, La.	1,454,684
Lake Pontchartrain, La.	1,100,277
Mermentau River, Bayou Nezpique, and Bayou de Cannes, La.	777,145
Bayou La Fourche, La.	870,522
Cedar Bayou, Tex.	530,977
Pacific Coast Rivers:	
San Joaquin River, Calif.	976,110
Sacramento River, Calif.	663,710
Umpqua River, Ore., including entrance	409,668
Coquille River, Ore.	451,948
Coos River, Ore.	632,469
Columbia and Lower Willamette Rivers below Vancouver, Wash., and Portland, Ore.	7,300,200

COMMERCE OF UNITED STATES WATERWAYS, 1937 —*Continued*

Pacific Coast Rivers—*Continued*

	Short tons
Columbia River from Vancouver, Wash., to The Dalles, Ore.	661,582
Skipanon Channel, Ore.	604,987
Willamette River (above Portland) and Yamhill River, Ore.	2,504,265
Youngs Bay and Youngs River, Ore.	811,814
Elokomin Slough, Wash.	536,425
Hoquiam River, Wash.	657,593
Snohomish River, Wash.	1,969,644
Westport Slough, Wash.	531,915
Coeur d'Alene Lake and St. Joe River, Idaho	356,239
Mississippi River and Tributaries:	
Mississippi River (Minneapolis, Minn., to the Passes)	28,307,790
Illinois River, Ill. (Ill. Waterway)	3,575,299
Missouri River: Mouth to Kansas City	416,474
Kansas City to Sioux City	566,706
Allegheny River, Pa.	3,436,550
Monongahela River, Pa. and W. Va.	24,927,507
Muskingum River, Ohio	839,465
Kanawha River, W. Va.	3,176,319
Ohio River, Pittsburgh to mouth	23,356,676
Cumberland River, below Nashville, Tenn.	468,881
Tennessee River, Knoxville to Paducah	1,377,107
Federal Canals and Connecting Channels:	
Cape Cod Canal, Mass.	3,538,566
Delaware River to Chesapeake Bay	1,436,828
Norfolk, Va., to Beaufort Inlet, N. C.	823,343
Jacksonville to Miami, Fla.	532,587
St. Marks River to Corpus Christi, Fla.	5,753,919
Lake Charles Deep Water Channel, La.	6,822,917
Sabine Neches Canal, Tex.	25,111,402
Aransas Pass to Corpus Christi, Tex.	6,615,525
Calumet-Sag Canal, Ill.	350,949
Grays Reef Passage, Mich.	5,575,681
St. Marys Falls Canal, Mich.	87,633,699
Chicago Sanitary Drainage Canal	2,469,822
Detroit River, Mich.	26,203,257
Multnomah Channel, Ore.	1,092,567
Canal and Locks at Willamette Falls, Ore.	565,369
Port Townsend Bay to Oak Bay, Wash.	472,814
Lake Washington Ship Canal, Wash.	1,731,016
State and Private Canals:	
New York State Barge Canal system	5,010,464
Navigation Canal, Inner Harbor, La.	1,822,618

The grand total (gross) for all rivers, canals and connecting channels was 342,343,716 short tons, valued at $5,939,272,119.

E. Relation of Waterways and Railroads. —In general terms the history of American internal waterway commerce has passed through three phases. The *first phase,* of growth, began as to our East coast with the colonization of the country, and as to the Middle West and West, with the advance of population in the 19th century. The rivers were usually the best, and frequently, the only means of transportation of freight and passengers, and without their utilization the settlement of the Mississippi Valley would have been vastly more difficult. In the first half of the 19th century there developed a large, flourishing and profitable commerce on the important rivers of the central valley. This was also a period of extensive canal construction, both in the Northeast and in the States bordering the Ohio and the Great Lakes. During this time there was no serious railroad competition. The *second phase,* of decline, dates roughly from the Civil War, and was synchronous with, and directly due to the expansion westward and southwestward of the great railroad systems. The *third phase,* which began some 15 or 20 years ago, is again one of growth, and of changed relations with the railroads.

The most important point to the student of the economics of inland waterways transportation, is its relation to rail transportation. Briefly, the proper conception of this relationship is that the two forms of transportation are correlative and are, or should be, co-operative, instead of competitive. This fact is beginning to be realized and acted on. The improper conception is that the two are naturally competitive and that one or the other must be driven from the field. This is the conception that ruled in the past. Throughout the second or highly competitive historical period, the railroads were the aggressors, usually with success, and the waterways were on the defensive, usually without success.

A railroad competing with a waterway has four important weapons. The first is the granting of competitive rates. A river can, of course, serve directly only the communities on its banks, whereas a railway can serve all communities. If permitted by law, a railway can lower its rates between water points until they are below what the water carrier must charge to earn money. If it does this the railroad will probably lose money on this particular traffic. It can however, recoup itself by correspondingly raising rates to off-water points. Thus it penalizes shippers on off-water points in order to drive the water carriers out of business. This end having been accomplished, rail rates between water points can once more be raised. Early railroad history was full of instances of this sort. Even after rail rates had been brought under the jurisdiction of the Interstate Commerce Commission, the practice of competitive rates continued, due to the commission so construing several successive laws under which it operated as to hold that railways could modify their rates in order to meet the effective water competition. It was not, indeed, until the passage of the Esch-Cummings act of 1920 that Congress wrote into a transportation act a full recognition of the Federal interest in fostering water transportation, in such a manner as effectively to influence the rate decisions along these lines. A study of the various Interstate Commerce acts throws a very interesting light on the gradual awakening of the country to the importance of its inland waterways.

The second weapon of the railroads has to do with joint rates. If a point a little distance from a river desires to enjoy the advantages of cheaper water transportation with another point on the same river, the freight must of course be gotten from the first point to the river bank before it is placed on the boat, and unless the distance is short enough for trucking, this part of the haul must be by rail. The shipper naturally desires to send his goods all the way through on a single bill of lading. If the railroad refuses to grant a through joint rate with the water carrier for the combined rail-and-water haul, the shipment cannot be made on a single bill of lading, which is likely to discourage the use of the rail-and-water route in preference to an all-rail route. If the railroad does grant a through joint rate, it may still demand, as its share of that rate, so large a proportion that the part remaining to the water carrier is insufficient to make it a paying concern. The commercial history of the Federal barge lines on the Mississippi-Warrior Rivers, referred to below, is one of continuous negotiation with the railroad in the attempt to get joint rates, and equitable divisions of those rates, so that both parties to the combined move could make a profit.

The railroad has also many natural advan-

tages over a river carrier. Except perhaps for some movement between river points, it can nearly always send fast or perishable freight more expeditiously. It can run its tracks to any point whatever. It can grant in-transit privileges which a water line would usually find great difficulty in granting. An important example is reconsignment privileges, by which a carload of goods can be shipped, say from Jacksonville, consigned to New York, and diverted enroute by telegraph to any other point, or held temporarily in a railroad yard, in order that the shipper may take advantage of the most favorable market. The railroads' ability to do this is due to the elaborate organization of their traffic, to the fact that they reach all important points, and to the fact that their carrying unit, i. e., the freight car, is a small one, which can be deflected or delayed without material effect on their operations.

Finally, the railroads, until quite recently have been far more efficient than the water carriers. The rolling stock, operation and organization of a Middle Western railroad in 1910 was incomparably superior to those of the same railroad when, 50 years before, it began fighting the water carriers on the Ohio and Mississippi Rivers. But in the same period there was in general little improvement of those water carriers. They did not have the capital or organization of the railroads, and they tended to an inefficiency and conservatism in their design and operation which might have been fatal to them even had not other means, both fair and unfair, been employed against them.

The situation thus brought about lasted without notable change almost until the World War. It was followed by a sudden and striking change. The most notable fact in American economic history in recent years has been the development of true *efficiency,* as distinguished from an activity which produced gigantic results but in a very wasteful manner. The growth of the country, the reduction of certain natural resources, and particularly the pressure of the war, taught us the lesson of the maximum economy in our commercial operations, which was learned long since by the more densely populated European countries. It is an inconvertible fact that, given an adequate channel and a modern and efficient water carrier, it is much cheaper to carry goods between two points by water than by rail. The country is beginning to realize that it is bad policy to permit the waste of this great potential asset of cheap water haul. On many of our principal waterways, notably in the Mississippi Valley, where for the past half century traffic was confined to short local hauls or to the movement of low grade material such as sand, gravel and stone, there has developed a demand for modern river freight service, and for equitable arrangements with the railroads so that unfair competitive rates shall be done away with, and so that joint rail-and-water hauls shall become practical. This is manifesting itself by the creation of modern terminals, the construction of suitably designed vessels, and a revision or pressure for revision of the rate structure.

One important factor has been the operation of the Federal Barge line, recently reorganized as the Inland Waterways Corporation, operating under government ownership and control on the Mississippi and Warrior Systems. It was established during the World War. Until very recently its operations showed a loss so considerable that private capital in all likelihood would either never have entered the field or would promptly have been driven from it. Being backed by the Government, however, it was able to take the loss, and at the same time to exercise continual pressure on the railroads for equitable rates and treatment. It is notable that many important railroad companies of the same territory have voluntarily made suitable arrangements with the barge line. During the calendar year 1935, the line carried 1,732,059 tons of freight, mostly medium or high grade, and showed a net profit of $703,107.38 on its investment after meeting maintenance, operating, and depreciation charges.

The full extent of this waterway recovery cannot be gauged by the statistics of the total traffic of the rivers. They have always carried a considerable tonnage, even in the worst years, and the *percentage* increase in many cases is not yet very large. The significant thing is the *character* of the increase, the change from purely local and low grade business to long hauls of medium grade material such as bulk grain and structural metal, and of high grade material such as package freight. Very significant in this connection are the activities of the important steel companies in the Pittsburgh district, which are now shipping their products on a large scale, in their own barges down the Ohio and Mississippi. The Ohio tonnage of this character has increased over sevenfold in recent years.

The changing attitude of the railroads is due to their realization of the proper relationship between rail and water transportation, which as stated above is that of co-operation rather than competition. The railroads will always be the backbone of internal transportation, and efficient water service cannot exist without their co-operation. On the other hand the waterways can perform very important services for the railroads. They can handle peak load movements, notably from large agricultural areas, which now on occasion tend to congest railroads, causing delays, damage to crops, losses to the shippers, and corresponding reduction of the purchasing power of the community, which in turn is reflected in smaller rail shipments of general merchandise. The waterways can in many cases enable the railroads to avoid the condition of an unbalanced haul, i. e., a heavy movement one way and a light movement the other, which of course involves a return haul of empty cars at a loss. The waterways can relieve the railways of much low grade bulk traffic, which it is difficult for the latter to haul at a profit, and the handling of which interferes with the movements of the high grade materials on which the railroads get their principal freight revenue. The waterways can assist in seasons of car shortage. Finally and most important, the saving arising from the inherent cheapness of waterways is a net saving and benefit to the entire community, which is certain to be reflected in its increased prosperity and purchasing power, and equally certain to be shared by all the important agencies of the community including the railroads themselves.

F. Theoretical and Actual Present Character of Waterway Commerce.—In an ideally co-ordinated transportation system, the question

of whether a freight movement would be by water would turn on four main factors.

1st. The peculiar adaptability of water transportation to low grade and medium grade bulk commodities. Where the value of the freight is small, the freight cost becomes a material item, and there is a more pressing need of seeking the utmost economy therein. Also the first cost and maintenance cost of the container become a material item, and it is far cheaper to build and maintain one 2,000-ton barge than forty 50-ton freight cars. Also this class of freight, moving on a single- or even double-track railroad, tends to slow down all movements thereon, while the same is not true on a river. Also its handling into and out of a single large container (barge) is usually less expensive than that for a number of small containers (freight cars).[1] Also it does not usually demand the fast freight or express service which the railroads *can* give to high-grade freight.

2d. The superior ability of the railroad to give express service between two points, unless one or both points are on or close to a connecting waterway, and unless the combined rail and water movement, if any, is very carefully organized. This is especially important in the case of perishables.

3rd. The inherent advantages possessed by railroads in such matters as intransit and reconsignment privileges, touched on above; particularly important where the shipper is a seller who must watch closely the price fluctuations in various markets.

4th. In any case involving a joint rail-and-water haul, the cost relations between line haul by land, line haul by water, and transshipment, it has been explained that, generally speaking, *line haul* by water, given suitable carriers and channels, is cheaper than line haul by rail, although the ratio between them varies widely. Assume a shipment from Jackson, Miss., to Springfield, Ill. This can go direct by rail at a cost per 100 lbs. which we will call R. It can also go by rail from Jackson to Vicksburg at a cost of R_1, thence by water to East St. Louis at a cost of W, and thence by rail to Springfield at a cost R_2. At both Vicksburg and East St. Louis it must be transshipped from rail to water. Call the transshippment costs T_1 and T_2. Then the total cost of the combined movement is $R_1+T_1+W+T_2+R_2$. Unless this is *less* than the single direct rail rate, the freight will not, and in the interest of economy, should not, move by the combined rail and water route.

The water route involves two costs which do not appear in the all-rail route, namely, the rehandling at Vicksburg and at East S. Louis. These two charges, in an economic computation, must therefore be absorbed into and spread over the cost of water haul between Vicksburg and East St. Louis, and will increase the cost per ton-mile of that haul.[2]

Evidently, the longer the water haul, the less its cost per ton-mile will be raised by the addition thereto of the fixed charges for rehandling. Two other elements are also to be considered. The combined haul will usually be longer than the straight rail haul, due particularly to the sinuosity of the average river compared to the average railroad. In the above illustration the shortest rail distance from Jackson to Springfield is 599 miles, but the distance by rail, water, rail is 926 miles. The other factor is that rail rates do not vary, and properly should not vary, *directly in proportion* to distance. The cost of a haul to the railroad itself consists of two parts, the cost of the line-haul proper and the cost of loading and unloading the cars at the termini, including switching, demurrage, etc. Naturally this fixed terminal charge affects the total cost per ton-mile more appreciably in short hauls than in long hauls. That is, it may cost the railroad only twice as much to load, haul 300 miles and unload, as it costs to load, haul 100 miles and unload. Therefore the rates which the railroad should properly charge for its two *short* hauls in the above example, namely from Jackson to Vicksburg and from East St. Louis to Springfield, while less than the rate for a single movement from Vicksburg to Springfield, are not less in proportion to the difference in distance; the *ton-mile* cost for either of the short hauls being greater than the *ton-mile* cost for the single long haul.

It is evident from the above that there will be many cases where a haul between two points, one or both of which is off water, can be made more cheaply by combined movement than by all rail; but also many cases where it cannot. Likewise, that the most important factor is the *relation of rail distances to water distances,* and that combined movement, to be truly economical, must in most cases involve a haul by water *quite long* in comparison to the rail hauls at one or both ends. Likewise, that the next most important factor is efficient terminal service and rehandling so that the costs T_1 and T_2 will be as low as possible.

With ideal organization we would therefore expect to see the following moving by water: (1) Nearly all low-grade and medium grade movements between all-water points. (2) A considerable part of all high-grade movements between all-water points, except that perishables would move to a limited extent only. (3) A large part of low and medium-grade bulk movements involving at least one land haul where the water haul was long in proportion to the land haul. (4) A smaller but considerable part of all high-grade movements, other than perishables, between such off-water points with a long water haul and short land haul. (5) Little or no movement of perishables between such points. (6) And very restricted movements in all cases where express service or reconsignment privilege are called for.

Considering the actual situation, case (1) is now the rule (coal in the upper Ohio Valley, logs in the west, oil, sand and gravel). Case (3) is the rule in some important cases (Western grain transshipped at St. Louis for New Orleans; ore, coal and grain on the Lakes, with one or two short rail hauls involved); but in other localities is not the rule. Case (2) is less general, though it is developing with efficient fast packet service (Mississippi, Hudson, Ohio, Sacramento). Case (4) is exceptional, existing

[1] This statement needs qualification in the cases where special and very efficient apparatus has been devised for loading and unloading railroad cars at points where there is an immense movement of a single bulk commodity.

[2] The published water rate may "absorb" the handling costs, so that the shipper is never billed specifically for them; i.e., the water carrier meets these costs out of the sums received for the line haul. This does not affect the principle involved.

only where, as on the Mississippi, equitable joint rates are being established.

In other words, the weakness of the waterways system is primarily in the *combined haul* province; and as between high-grade and low-grade freight, is primarily in the *high-grade* province. The second weakness involves line-haul and terminal efficiency on the waterways, touched on elsewhere. But both weaknesses need, for correction, continued readjustment of the relationship of rail and boat; and we end as we began, with the fact that this relationship is the key to inland waterway economies.

G. Benefits and Justification of Inland Waterways.—The principal benefits of improved inland waterways to the general public, or to any section of the public or to individuals, are:

(1) Reduced transportation costs, by a movement by water inherently cheaper than the same movement by rail or other means.

(2) Reduced transportation costs on material which, though it continues to move by rail, moves at a less cost through the reduction of rail rates to meet water competition.

(3) Increase in the value of land or other private investments.

(4) General development of tributary territory.

Of the above (4) is often of unquestioned importance. Large sections of our country would perhaps never have been developed to the point which they have reached today, and could certainly not have been thus developed so easily and cheaply, without the use of natural or improved water channels. This factor is, however, necessarily not computable in definite terms. Benefit (3) may often be very great, but is likely to affect only a limited number of individual owners. Therefore the student of economics, seeking a conception of general waterway benefits expressed in reasonably accurate terms, must usually confine himself to (1) and (2).

Referring to (2), it is of course true that when a railroad, in order to meet water competition, lowers its rate for certain hauls, all the shippers affected are benefited. Obviously, however, if the railroad does not raise its rates elsewhere, this benefit is at the direct expense of the railroad stockholders. If, as often occurred in the past, and as is mentioned above, the railroad does raise its rates elsewhere, the benefit to the favored shippers is at the expense, not of the railroad stockholders, but of the shippers in less favored non-competitive territory. Whether this shifting of money, so to speak, from the pockets of one shipper, or of a railroad stockholder, to the pockets of another shipper, is equitable, must depend in any specific case on whether past and present rail rates are too high, or too low, or to what extent, before the change, they were equitably distributed as regards to the various sections which the railroad serves and the various goods which it carries.

The subject of rail rates, which lies outside the scope of this article, is an exceedingly complex one. Many years ago the Government established the Interstate Commerce Commission as an agency for dealing with and regulating, among other things, rail rates. Such a Federal agency being in existence, empowered to regulate rates and operating under specific statutes and broad principles of equity, it is evident that the Federal Government should not in logic undertake activities which have for their sole end the regulation of those rates by other means. Congress has therefore frowned on the policy of improving inland waterways for the purpose of forcing a modification of rail rates. Any waterway project may have this incidental effect; but the recommendations of the War Department, and the action of Congress on any project tend to disregard this, and to give consideration solely to benefit (1) above, namely *the savings to the general public by commerce which, as a result of the improvement, will actually move on the waterway at a saving in actual transportation cost.*

The improvement of a water channel thus becomes in principle in no way dissimilar to the undertaking of any ordinary business enterprise. The improvement will cost a certain amount, which may be considered as capital cost, allowed for on the books by a reasonable carrying charge, say 4 per cent or 5 per cent, the range over which in former years the Government has borrowed money. The maintenance of this channel, plus the operation of locks, if any, constitutes an additional charge; and the sum of the two is in effect the annual cost of the waterway to the Government. Both figures can be arrived at in advance with considerable accuracy. The corresponding benefits consist of the tonnage which will annually move over the improved channel, multiplied by the saving per ton to the shipper moving his goods by this means instead of moving them by some other means. This saving, of course, does not go to the United States Treasury, but to the shippers who use the waterways, and in a diminishing degree to the purchasers of the goods, and, through various ramifications, to individuals or communities throughout the country. Nevertheless the Federal Government, being merely the agency of the American people, considers it sound business to invest a part of their money, collected by taxation into the Treasury, in waterway improvement, provided a reasonable profit to the people is made thereon through reduced transportation charges to various shippers, industries, etc., and provided these benefits are sufficiently widespread to make the matter of national rather than of purely local importance.

In thus balancing cost against benefits there must be considered: The actual amount of the gross savings, the degree to which they are distributed through the nation, and the proportion which they must bear to the cost in order to make the waterway a paying investment.

The estimate of gross savings involves a forecast of tonnages and of rate differentials. The accuracy with which it can be made varies greatly in different cases. It can, of course, never be arrived at with the same accuracy that inheres in a strictly engineering computation. A variety of factors enters. Differential rate figures are necessarily based on existing rail rates, whereas the improvement of the waterway may result in a change of these rates to an unpredictable extent (though the tendency is far less than in the past). Again, commerce tends to follow existing channels of transportation, all details of which are familiar to shippers and consumers, even though alternative channels may be in existence which

possess potentialities of savings. Again, where the use of the water channel would involve a combined rail and water movement there is opened up the whole complicated question of through the bills of lading, joint rail and water rates and their divisions, touched on above. Again, the utilization of a water channel involves the existence of capital willing and able to build and operate boats and terminals, and to make the necessary arrangements for interchange with land carriers. Again, as we have seen above, the character of the material to be moved is an important factor.

All these and other questions enter into estimates of the future commerce and future savings of the waterway, which form one of the most complex studies that confront the army engineers who make recommendations on such improvements. The inevitable uncertainty of such estimates in most cases leads the Government to undertake improvements only when the benefits, according to the best possible estimate, are well in excess of the cost. The situation is analogous to that of a man who invests capital in a business, the returns of which are somewhat uncertain, and who therefore naturally demands a larger prospective profit to compensate him for the risk. No exact formula in the case of waterways has been or can be evolved, as conditions vary so greatly. Speaking generally, it is not the tendency of Congress to adopt a project unless probable benefits, computed as above, are at least several times the annual costs to the Government computed as above.

The question of the *spread* of these benefits is one of fact and judgment. It is impossible to imagine a waterway, the benefits of which are shared in an exactly equal degree by all the people of the United States. Even with channels of such immense national importance as the entrance to New York Harbor, or the connecting channels of the Great Lakes, or the Panama Canal, there will be certain individuals and interests who derive a very material and immediate cash benefit therefrom, and other citizens to whom the benefit is either negligible or so indirect as to be incalculable. If, however, a certain channel will visibly benefit a large city, or an important section of the country as a whole, or will produce savings to an important group of interests whose products enter largely in the general commerce of the country, the tendency of Congress is to consider this as a national benefit which, if the savings in sight are large enough, justifies Federal assistance. If the apparent benefits are exclusively to a small community or a few individuals it is not a proper case for Federal assistance. There is an intermediate class of cases, where, while considerable national benefits are in sight, so large a share of purely local benefit is also visible that Congress demands co-operation in the project, usually in the form of a percentage (perhaps 50 per cent of the first cost, paid into the Treasury in advance). Many such co-operative projects are in existence, notably on the Pacific coast. There is also a tendency for the Government to confine its improvement to main channels of approach or arteries of commerce, leaving to localities the provision of branch channels, approaches to terminals and so on.

A computation of the total economic benefits of all the internal waterways of the country is an immensely intricate process. An attempt to work it out in elaborate detail would result in discovering so many factors incapable of exact evaluation that a rigidly accurate answer would be incapable of even theoretical determination. It is, however, possible to obtain a figure of the general «order of magnitude» of the correct one. The annual cost to the United States of its improved inland waterways, excluding the Lakes system, is not over $20,000,000. Annual direct freight savings work out at about $35,000,000, which is almost certainly small enough and may be as much as 50 per cent too small. Within the margin of error of such work it is therefore safe to say that our inland waterways carry themselves on a financial basis and return to the people an annual dividend of at least $15,000,000, perhaps several times as much, on the capital investment which the people, through taxation, have paid for their creation and upkeep. These figures, of course, disregard entirely the investment and operating costs of vessels, terminals, etc., owned privately; but since these exist and carry on business, it is evident that in the general case they operate at a profit.

The above figures are based upon the single factor of direct savings on freight actually moving by water. If all factors are taken into account they are obviously far too low. They disregard the incalculable factor of stimulation of trade and industry. They disregard the immense total increase in land and other values resulting from waterway improvements. They disregard the fact that many flourishing developments, agricultural, industrial and mining, would not be practicable at all were it not for the existence of water transportation. They disregard also such entirely non-navigation aspects as benefits of the Mississippi River improvement in the flood control of the lower valley, which in land values can probably be evaluated at billions of dollars. Finally, the figures take into account the cost to the United States of *all* Federally improved inland waterway channels, even though these are not now returning, so to speak, a profit. A number of instances exist of rivers which many years ago and over a long period carried so flourishing a commerce that they paid for themselves several times over, but on which for various reasons commerce has fallen into decay. These represent what in private business would be written off the books as obsolete plant that has been amortized. Such projects, granting the amortization of the funds originally spent on them by the benefits derived in the past, are no charge whatever on the Government. There are numerous such small waterways which remain on the books as technically approved projects, but on which for many years no money whatever has been spent, or will be spent unless a revival of actual or potential commerce should make it once more worth while. It is cases of this character which are sometimes mistakenly cited as examples of so-called Federal extravagance in waterway improvement.

H. Types of Carriers.—The full economy of internal water transportation can only be secured by vessel construction following the trend of mechanical development. In certain special cases this has occurred over a long period. The Great Lakes have developed a form

of large steam propelled ships of extraordinary efficiency. Excellent passenger and freight carriers operate on the Hudson River, between San Francisco and the Sacramento-San Joaquin system, on Chesapeake Bay, and at many other localities. On a few rivers, such as the Monongahela, where an extensive specialized commerce has developed, barge traffic has been brought to high efficiency. Generally speaking, however, until the marked revival of interest in inland water transportation of a decade ago the tendency was to depend on less efficient boats. The river steamers of the old steamboat days of Mississippi Valley history had not been adequately modernized, nor has barge traffic been properly developed. For further discussion of these vessel types see STEAM VESSELS.

Great strides have been taken in recent years in this direction. Among which may be mentioned the experiments and experiences of the Federal Barge Line on the Mississippi, Illinois, Missouri and Warrior rivers; the elaborate practical and theoretical studies of efficient forms of river transportation made by the so-called Towboat Board of Army Engineers; and the construction of floating plant by large corporations, on the Ohio system and elsewhere, for the movement of their own products. The following are the most important lines along which progress is to be made:

Propelling Machinery.—There is a large field for the introduction of more efficient machinery, either of modern steam engines or of Diesel.

Tunnel-Boats.—These are a form of screw propeller boat designed for operation in channels of limited depth, alternative to the stern-wheeler for towboat service on rivers. There is much controversy as to the merits of the two types, which cannot yet be considered settled. Irrespective of the undoubted merits of the stern wheel vessel, the tunnel-boat has great possibilities and is capable of further development.

Barges.—Transportation of freight by a fleet of barges propelled by one or more towboats is of course exceedingly economical, since the greater part of the freight is carried on vessels that do not have to be equipped with propelling machinery. This has long been recognized, and in the days before the temporary decline of Mississippi commerce, immense quantities of coal were shipped from Pittsburgh to the lower Mississippi by barge fleets. The old barges were, however, cheap structures of wood, the upkeep of which was expensive, and which were not suitable for anything except crude bulk freight. Modern construction tends to steel barges, so equipped that they can be used either for bulk freight or for package freight which requires shelter and more careful handling, and designed for maximum carrying capacity on limited draft. Such barges are rapidly coming into use on the Mississippi, Ohio and Hudson-Barge Canal systems. The oil companies are very active in developing tank barges. A demand exists for the design and introduction of an efficient refrigerated barge which can handle perishable agricultural products on a large scale.

Self-Propelled Barges.—A somewhat different line of development is toward a vessel which is self-propelled, and at the same time designed for a greater freight carrying capacity than the ordinary river steamer. These are coming into use on the lower Mississippi, and there is talk of similar development on the upper Mississippi and Hudson.

Light Draft Vessels.—The problem of economical water transportation on channels of 6 or 7 foot depth or more is not entirely solved, but the principal elements of its solution are at hand, and the rest is largely a matter of time and capital. A more difficult problem is the development along modern lines of crafts suitable for channels of 3 or 4 feet in depth. Such depth limitations greatly restrict the carrying capacity of a vessel, whether self-propelled or a towed barge, and the limitation on the amount of freight which can be carried seriously affects the revenue.

A great stimulus has been given to navigation on such shallow draft waterways in recent years by the development of the gasoline engine to a point where small and medium sized motor boats are comparatively cheap and foolproof, and there is a commerce carried in these vessels which in the aggregate is surprisingly large. This is however mostly of a local character, typically that pertaining to a single farm or small industry. An organized long haul business would require different treatment, involving perhaps the use of carefully designed light draft vessels propelled by gasoline or Diesel engines and handling a few cheaply but efficiently constructed barges. A great field for such transportation exists in the rivers of the Southeast and on the smaller tributaries of the Mississippi system.

I. Terminals.—As has been pointed out above, in almost no case can material move direct (i.e. by man or fixed mechanical handling) from origin to vessel and from vessel to destination. Even when the movement originates and terminates at communities on a waterway there is nearly always at least a truck haul to or from waterside, and in fully developed water transportation there will be in many cases a rail haul at either one or both ends of the water haul. Whether the land movement be by rail or truck there is involved an assembling of sufficient freight to fill the river carrier at the origin, and storage of this same freight at the destination until the land carriers can remove it. The cost of storage and handling at both ends is a legitimate part of the cost of water movement, and for the latter to develop its full economy these terminal charges must be minimized. Efficient terminals are therefore a vital element to water transportation. In no department of river transportation was less efficiency shown in the past. On many rivers the terminal problem was solved by the steamboat simply loading from or to the natural bank of the river, where sometimes a crude protection from the weather was provided. On the Ohio and Mississippi the common practice was to pave a stretch of sloping river bank with cobbles, so that no matter at what stage the river stood, the steamboat could come alongside and find firm ground for loading or unloading. A variant was the wharf boat, a barge moored along the bank, rising or falling with the stage of the river, to one side of which the steamboat would tie up and across which freight would be handled to the bank. Striking as it may seem, until very recent years such elementary methods, combined with the handling of the material by man power or by crude and inefficient machinery, were almost

universal. (This statement of course does not apply to the Great Lakes, nor to a few waterways such as the Hudson and the rivers of the upper Ohio Valley.)

Correspondingly, in no departments have more rapid advances been made in recent years.

The principles of efficient inland waterway terminal construction are in general the same as for sea-port terminals (See HARBORS, DOCKS AND BREAKWATERS). The two most important differences are: first, the prevalence in river transportation of barges and barge fleets carrying bulk commodities, which require a somewhat different arrangement of machinery for handling than to shiploads of similar commodities; second, and more important, the variation in stage of any rivers. Seaport terminals must be adapted to changes in tidal stage, and where there are great tidal variations, as in Northern Europe, special construction is necessary; but in the United States, tidal range is ordinarily too small to exercise a profound effect on ocean terminal design. On many of our large rivers, however, there are variations in height as great as 30, 50, or even 70 feet, and special treatment is called for.

Modern river terminals where variation of stage must be taken into account, are of three main types:

(1.) What may be called the normal inclined lift.—Here we have at the top of the bank, above flood water, a storage and assembly shed, and leading down the bank from this to the river an incline, sheltered from the weather, in which operates some form of mechanical conveyor. The conveyor track is jointed, and the lower end rests either on a gang-plank arrangement extending to the river carrier, or preferably on a wharf-boat. A vessel, to unload, moors to the outside of the wharf-boat; the freight is taken into the wharf-boat (which may be used as is a transit shed for the temporary shelter of freight) and is then placed on suitable carriers, say ordinary hand trucks, which are attached to the mechanical conveyor and hauled up the bank to the storage shed. Loading cargo on to the vessel is by the reverse process.

(2.) What may be called the parallel inclined lift.—This is designed to avoid two handlings, between the river boat at the bottom of the bank and the railroad cars at the top, by carrying the cars down to the river's edge. A spur track is built diagonally down the face of the bank at a sufficiently gentle slope so that a locomotive can move freight cars up and down it. The trestle on which the track is carried is built down to the level of low water. A barge is then constructed which carries, down its centre, a length of railroad track, and which is long enough to accommodate a suitable number of freight cars. One end of this barge is in contact with the fixed trestle so that there is a continuous track down the trestle and on to the barge. The barge, of course, rises and falls with the stage of the river; as the river rises, the barge is pulled along in the direction in which the trestle runs so that the rail connection between the two is always maintained. Thus there is in effect a jointed floating railroad spur. Alongside this barge carrying the track is ordinarily moored another barge which is the true wharf-boat. The river vessel ties up outside the wharf-boat and the freight is unloaded through it (being assembled temporarily within, as in a transit shed) and thence into the cars on the first barge.

(3.) Vertical lift.—In this system a fixed, or gantry, crane is built out from the top of the bank, suitably supported, to such a distance that at any stage of the river it overhangs a river vessel brought alongside the bank. The material is lifted mechanically directly from the vessel and carried up and then back to a point where it can be lowered into railroad cars, or alongside a transit shed or storehouse on the top of the bank.

Of these three methods, which are of course susceptible to many variations, (1) and (2) are obviously a combination of the old paved bank and wharf boat system, but with the introduction of mechanical handling and of suitable shelter for package or perishable freight. No. (3) is simply an adaptation of the ordinary wharf-side handling machinery of a seaport to the special conditions of high lift made necessary by great river variations.

Where no large variation in river stage occurs, the principles of terminal construction do not materially differ from those at ports save as the different capacities and dimensions of the river carriers must be taken into account.

Within recent years, largely by or under the stimulus of the Federal Barge Line, the principal cities of the Mississippi have installed various types of modern and efficient river terminals. Great activity is noted along the same line on other important rivers, notably on the Ohio, Warrior, Illinois and Missouri as the various communities make ready for the large general commerce which will inevitably develop.

The above remarks regarding the former inadequacy of river terminals apply more particularly to package freight and to freight handled by common carriers. In specialized cases, mechanical handling of bulk commodities by large individual corporations has become highly mechanicalized and efficient.

J. Future of Internal Waterways.—There is no doubt that the revival of American internal waterway traffic which has been so notable in recent years, will continue at an increasing rate. Inexorable economic law is driving the country to seek the most efficient way of carrying on the great processes of national life. It is sufficiently astonishing that the possibilities of immense savings, running into the hundreds of millions a year, through the intensive use of inland waterways, should have been overlooked so long and to such an extent as they have been. The current development is warrant that they will never be thus overlooked again.

From the point of view of channel construction, the broad lines of the future internal waterway systems are evident, and the channels themselves are in general completed or well advanced toward completion; what remains is the filling in of gaps and the linking up of certain isolated projects. A 9-foot waterway is now available from Pittsburgh to the Gulf of Mexico, with channels 6 feet to 9 feet deep on all the important Ohio tributaries; 9-foot channel from the mouth of the Ohio to St. Louis, and thence via the Illinois waterway to the Great Lakes at Chicago, a 9-foot channel will in 1938 be available to Minneapolis on the Mis-

sissippi, while by that time a channel 8 to 9 feet in depth on the Missouri up to Sioux City, Iowa, will also be available. These form the backbone of the Mississippi Valley system. Two important connecting channels are practically assured; first a 9-foot intracoastal waterway west from New Orleans down the Louisiana and Texas coast, and a suitable channel east to Mobile, whence the Warrior connects the main system with the Birmingham district and the Alabama coal fields. Second, the Great Lakes system, as concerns Lake traffic, is complete from Duluth to Buffalo, and the new Welland Canal ties in Lake Ontario. New York's 12-foot barge canal connects this system with the Hudson Valley and the Atlantic at New York, and Canada's 14-foot canal connects with the Atlantic via Montreal. On the Atlantic coast the existing intracoastal system, provides a continuous sheltered waterway from southern Florida to the industrial Northeast. The San Joaquin-Sacramento system is operating with great success. The numerous branches and minor tributaries of these four systems are in general already in shape, or with limited expenditure could be put in shape, to serve as feeders to the main arteries.

The full development of the Columbia system turns on the construction of dams on the Columbia and Snake, to develop the immense potential electric power here available. This will go hand in hand with navigation development, and power and navigation between them will build up a great Northwestern empire in the rather sparsely populated and undeveloped territory east of the Sierras.

The future of the Southeastern rivers, except in certain special cases like the Warrior, turns principally on two factors. One is their relation to the intracoastal waterway from Chesapeake Bay to Southern Florida. These rivers will then serve as feeders to that waterway and their commercial importance will thereby be greatly increased. The second is the solution of technical navigation problems, either by a greater depths or by the development of economical carriers for depths now provided. Sometimes one and sometimes the other will be required. In the majority of cases, what is lacking is less a good channel than an efficient use of it by efficiently designed shallow-draft carriers. The terminal problem must also be solved, with due regard to the violent fluctuations in the stage of most of these rivers. The same remarks apply to many minor tributaries of the Mississippi system, notably in the lower valley, and to important Texas rivers.

K. Co-ordination of River Development.—«River Planning.»—Mention has been made of such rivers as the Columbia and Tennessee, where power development by the construction of dams and regulating reservoirs must go hand in hand with navigation development. This is true of various streams, and the same principle applies to other interests. It is difficult to use a river for any important economic purpose without affecting, for good or ill, its utilization for other purposes. Thus, water power development tends to provide a canalized river and to make the flow more uniform, features in general beneficial to navigation, though the regulation of flow by power dams has on occasion been detrimental to navigation. Irrigation tends to withdraw from the river a certain amount of its flow and affect adversely both navigation and power. Flood control, if combined with protective works, such as levees, tends to hold the high water channel in place and cause it to scour deeper, thus benefitting navigation. Flood control by retention reservoirs to catch large floods is likely to be beneficial to both navigation, power and irrigation. Restriction of the flow of the river by any means at low water seasons may result, if the river ends in a tidal estuary, in salt water working up that estuary to the damage of neighboring agricultural land.

Thus the problem of a river must be envisaged *as a whole,* and every effort must be made to co-ordinate the various uses that the maximum of benefits results to all, and damage to none. This will nearly always imply some compromise, as the utilization of a river to the limit by any one interest regarding only itself may seriously damage other interests. Such a situation has already developed on certain rivers. This matter of what may be called, to borrow a term from the city planners, «*River Planning,*» is one worthy of the best attention of statesmen and engineers.

L. Comparison with Foreign Waterways.—The statement is often made that America lags behind Europe in the utilization of its inland waterways. This needs qualification. We have little to learn from Europe in *river engineering.* Modern American practice in locks and dams and in river regulation is fully up to European practice; in efficient dredging we are probably ahead of Europe; and the problems of certain of our rivers, such as the Mississippi system, are on a more gigantic scale than anything that Europe has to face. Also, where we have intensively developed our inland waterway commerce, as in the upper Ohio valley and the Great Lakes, I believe that we are abreast or ahead of Europe in economy and efficiency of transportation.

The real distinction is that found in many other fields, and is characteristic of the two cultures. Europe has arrived long since at the phase of dense population and intensive competition which we are now entering, and has learned the lesson, which we are now learning, of high efficiency and of careful planning and large capital expenditure to effect small savings. The Continental nations also tend much more than do we to government control of economic activities. We are behind Europe in such departments as efficient river craft for miscellaneous package movements on shallow draft streams, adequate terminals therefor, and a sound economic relation between water and land carriers. In the large European nations, notably Germany, problems of this character have received careful study by the central, provincial and municipal governments which own and operate terminals and transshipment facilities, just as in many cases they own and operate the rail and water carriers. Such degree of governmental control and operation is contrary to our national genius. Nevertheless, while the end must be attained here by working along more individualistic lines, it is the same end. We can with great profit to ourselves study the achievements of Europe in the matter of organized inland waterway commerce, while using our own methods to equal and surpass them.

II. The Great Lakes

From the point of view of commerce and navigation, the lakes are in a class by themselves. On the one hand, the system is strictly speaking an inland waterway, water connection to the sea being as yet possible only for inland waterway craft or the smaller types of ocean-going vessels. On the other hand, the lakes are themselves great inland seas, with ample natural depth for any ship afloat except in the harbors and connecting channels, susceptible to storms as serious on occasion as those occurring in the open ocean, and therefore navigated primarily by vessels which, though specially designed, are of the general magnitude of large ocean ships.

A. Agencies and Means of Improvement.—The agencies of improvement and the methods of obtaining and carrying out approved Federal projects are the same as with *Inland Waterways* (q.v.). Work done by the Federal Government consists, first, of the improvement of various lake harbors, of which the more important are mentioned below. A characteristic of harbor engineering on the lakes is the prevalence of breakwaters; the majority of the harbors had little or no natural protection, and it was necessary to create by breakwaters enclosed areas in the open lake or to protect the entrance to inner harbors where these were present. Due to the absence of tide and consequently of tidal scour, jetties constructed specifically for regulating purposes are not found. Entrances to lake harbors are frequently protected by a special lay-out of breakwaters known as the arrowhead type, diverging from the entrance to the shore in such manner as to produce a stilling basin and ameliorate wave effect.

Beside harbor work, the Federal Government has improved the connecting channels from Lake Superior to Lake Huron via the St. Marys River (Sault Ste. Marie or «Soo») by locks and dredging and has improved by dredging the connection from Lake Huron to Lake Erie via the St. Clair and Detroit Rivers. The connection from Lake Michigan to Lake Huron via the Straits of Mackinac has required but minor improvement. Connection from Lake Erie to Lake Ontario is made on the Canadian side by the Welland Canal. A navigable barge connection exists on American soil, using the main New York State Barge Canal to Three Rivers and thence by the Oswego branch of that canal to Oswego, but there is no record of any very considerable movement by this route.

From Lake Ontario there is a navigable connection by the St. Lawrence River, together with lateral canals on Canadian soil, to Montreal, which is a great ocean port.

B. Channel Depths.—At the adopted datum of mean low lake level, there is a through channel 24 feet deep in the St. Marys, St. Clair and Detroit rivers, and a channel 23.5 feet deep through the Welland Canal. The connection from Lake Ontario to Montreal is 14 feet deep.

All harbors in the four upper lakes handling an important commerce have depths of at least 18 feet, which is generally considered the least on which economical navigation can be carried on, using the modern type of vessels. The principal harbors and connecting channels have been or are being improved to provide a depth of 24 feet for downbound navigation.

The lake carriers utilize available depth to a much greater extent than do ocean carriers. It will be seen below that, while at our seaports 30 feet is generally considered as an appropriate depth for a first-class port handling a general foreign and coastwise business, the great majority of ocean shipping operates on considerably less draft. On the lakes, on the other hand, the bulk of the freight is carried in vessels designed to draw, when fully loaded, practically the entire amount of water available; and moreover, these vessels actually load to within an extraordinarily short distance of the existing depth, often entering or leaving harbors with but a few inches under their keels. Seasonal variations in depth are watched very carefully by the carriers, and vessel loadings are varied to correspond to them.

C. Commerce of the Lakes.—The principal commerce is in three bulk commodities of iron ore, grain and coal, and the less important items of limestone and pulpwood. This bulk traffic comprises probably the most efficient large-scale waterway commerce in the world. The iron ore moves from the Lake Superior mines mostly to the Lake Erie ports, where it is transferred to rail and carried to the great steel producing area of Pittsburgh and eastern Ohio. A total of 22,945,299 tons of ore moved over this route in 1934. It formed the major source of supply of our Ohio Valley steel industry, and the cheapness of the movements is directly reflected in the price of iron, steel and all their products. Grain, principally wheat, moves in great quantities from the American northwest to Duluth, Superior, Chicago and other ports, and from the Canadian northwest to the ports of Lake Superior. Thence it moves by water to American grain receiving ports on the lower lakes, principally Buffalo, or to Canadian lower lake ports for transshipment to Montreal, either by small lake vessels through the Welland and St. Lawrence Canals or by rail. The Buffalo grain destined for export moves east from Buffalo and other ports, to some extent by the New York State Barge Canal, but more largely by rail. The grain movement through the locks of the Soo in 1934 was 4,395,308 tons, and has been considerably higher in years of larger crops. The third movement is of westbound coal carried as return cargo by the same vessels from the Lake Erie ports to the upper lakes. In 1934 the movement through the Soo was 10,408,029 tons. There are lesser movements of limestone, pulpwood, etc., a considerable crosslake movement on Lake Ontario, and an important car-ferry movement across Lake Michigan by railroads which ship from East to West in this manner in order to avoid the congestion involved by routing through Chicago.

The package freight movement on the lakes is considerable. Considering, however, the extremely rich area tributary to the lakes, and the possibilities presented by them and by the New York State Barge Canal and Hudson River for through movements between the Middle West and the seaboard, such general commerce is far behind its ultimate potentialities.

The following table shows in summary form the commerce of leading Great Lakes ports:

COMMERCE OF THE GREAT LAKES

PORT	Short tons 1934	1937
Agate Bay, Minn.	3,663,678	11,118,361
Duluth-Superior, Minn. and Wis.	25,550,181	57,138,579
Ashland, Wis.	2,879,884	7,006,915
Presque Isle, Mich.	.....	4,674,744
Marquette Harbor, Mich.	847,763	1,157,763
Sault Ste. Marie, Mich.	560,169	838,612
Escanaba, Mich.	1,994,347	3,799,762
Menominee, Mich. and Wis.	664,463	826,591
Green Bay, Wis. (including De Pere)	1,872,454	2,529,282
Manitowoc, Wis.	1,225,081	1,361,544
Milwaukee, Wis.	6,083,400	6,617,802
Chicago, Ill. (including Chicago River, and Chicago and Calumet harbors)	8,319,809	18,612,301
Indiana Harbor, Ind.	5,455,215	7,936,660
Gary, Ind.	3,234,701	8,212,040
Muskegon, Mich.	1,130,104	1,896,093
Ludington, Mich.	1,571,232	1,720,560
Port Inland Harbor, Mich.	999,936	2,428,861
Frankfort, Mich.	898,519	1,176,748
Calcite, Mich.	3,262,258	7,401,210
Saginaw River, Mich. (ports on)	1,423,192	2,557,718
Detroit, Mich. (port of)	9,464,923	14,919,486
Toledo, Ohio	18,325,267	25,465,642
Sandusky, Ohio	6,341,507	8,102,772
Huron, Ohio	1,105,732	1,594,865
Lorain, Ohio	3,843,398	6,702,854
Cleveland, Ohio	8,658,596	17,385,842
Fairport, Ohio	2,506,988	4,237,657
Ashtabula, Ohio	6,366,898	12,393,058
Conneaut, Ohio	5,521,591	14,236,267
Erie, Pa.	4,091,017	6,537,160
Buffalo, N. Y. (by lake)	12,070,914	19,390,446
Buffalo, N. Y. (by New York Barge Canal)	1,751,756	1,627,211

The gross total for all Great Lakes ports was 296,493,500 short tons in 1937, valued at $3,743,590,241.

D. Ports and Terminals.—From a commercial point of view the harbors fall into the following classes:

(1) Those handling exclusively or almost exclusively the bulk commodities. The principal ones are Duluth, Agate Bay, Ashland, Escanaba, Marquette Bay, Toledo, Sandusky, Vermilion, Lorain, Fairport, Ashtabula, Conneaut and Erie.

(2) Those handling a considerable general commerce. The principal ones are Chicago, Milwaukee, Detroit, Cleveland and Buffalo, and there are a number of small ones, especially on Lake Michigan. Some of these, such as Buffalo, also handle a very large commerce of the bulk commodities. (It is not to be understood that these are less important than «(1)»; sometimes they are more important.)

(3) The car ferry ports, especially those on Lake Michigan. This lake, projecting so far south, tends to crowd down to its southern end, at Chicago, the trunk lines connecting East and West, resulting both in additional distance and in very serious congestion. A number of car ferry lines have therefore been established across Lake Michigan, with the very beneficient result of by-passing much of this traffic around Chicago.

(4) Finally there are some small fishing harbors, and some harbors, especially on the southern peninsula of Michigan, which in former days handled a great commerce in lumber and more than justified their existence, but which with the cutting out of the Michigan white pine have either relapsed into obscurity or turned to general commerce.

The shipping and receiving terminals for the major bulk commodities of the lakes have, like the other factors of this traffic, been brought to high degree of efficiency. Special machinery on a gigantic scale has been devised for the rapid dumping of ore, coal and grain into ships and its rapid removal therefrom. The construction of the terminals is closely co-ordinated with the construction of the ships. The record speeds to date are 16½ minutes for loading a 12,000-ton ship with ore, and 3 hours and 5 minutes for unloading the same quantity. This, of course, was a special performance. On the average, however, loading takes from 5 to 10 hours and unloading from 18 to 24 hours; and the big carriers are in the habit of leaving port almost immediately after they have received their loads, and of starting to unload almost immediately upon their arrival. The efficiency of this performance will appeal particularly to anyone who is familiar with the much longer «turn around» which is the usual rule at even the best organized seaports. Allowance must of course be made for the specialized character of the freight on the lakes, which lends itself to rapid handling, and for the immense volume which makes it economical to install highly expensive apparatus for this purpose.

Generally speaking package freight terminals have not been developed to a corresponding degree of efficiency. In this department, somewhat the same remarks can be made about the lakes ports as are made below regarding ocean ports.

E. Relation of the Lakes to Railroads.—The lakes form a channel of transportation alternative to that by rail.* In principle, therefore, their economics might be considered analogous to those of ordinary inland waterways as discussed above. The influence of a competitive spirit on the part of the railroads is definitely shown in the limitations of package freight movement. Forty or fifty years ago the lakes, especially the lower lakes, were fed by railroad lines running north and south, which were usually independent of the trunk lines that were beginning to develop east and west, and which, so to speak, played off the lakes carriers against the trunk lines for the haul to or from seaboard of the freight carried by them (the north-and-south railroads). This period was followed by railroad consolidation, and by agreements and understandings which are the basis of the present rate structure for so-called Central Freight Association Territory. As an additional means of suppressing water competition the trunk lines acquired the more important lake carriers. Several years ago the Interstate Commerce Commission formally divorced the lake general cargo carriers from the railroads. It is sometimes asserted that in spite of this action, the railroads are still able to exert a strong indirect influence over the activities of the water carriers. Whatever the truth as to this situation, there is no question that general cargo movement on the lakes is capable of great expansion.

The bulk traffic is however, another matter. We are not aware that the rail carriers have seriously attempted to take this away from the lake carriers; but if they should, they would enter a field where, as distinguished from the ordinary situation with regard to inland water-

*Excluding the car ferry movements, which represent practically floating bridges in extension of railroad systems and are organized and fostered by the railroads.

way movement, they would have to meet organization and capital comparable to their own.

The largest of the bulk movements—one-third of the total of 1935—is the eastbound iron ore, the terminals and carriers for which are controlled by the great steel corporations. Similarly, the eastbound movement of wheat at the cheapest possible figure is a matter of interest to the great dealers and exporters of that commodity. Finally, coal moves west in such quantities, because the predominating bulk movements (ore and grain) being eastbound, the carriers are naturally seeking a return cargo, and will make low rates and furnish good service to obtain it.

It is highly unlikely that any railroad or combination of railroads could, if it desired, seriously affect this movement by a rate war or by any other weapon such as in the past has been used against other inland waterways. It is also highly unlikely that any railroad or combination of railroads desires it.

This situation is an excellent illustration of the theory, advanced elsewhere in this article, that the proper relation of rail and water carriers is co-operative rather than competitive, and that the two may occupy a common field in their respective capacities with benefit to both. The magnitude and national benefit of the lake commerce is evident, and the important carriers and lines are commercially successful. Nevertheless, the neighboring territory is covered by a network of railroads which likewise are highly successful. It is unquestionable that a sudden stoppage of the Great Lakes' traffic would be as serious and embarrassing a matter to the railroads of this territory as it would be disastrous to the nation.

F. Benefits and Justification of the Lakes Channels.—The economic principles on which the channels and harbors of the Great Lakes are improved are in general identical with those applying to other inland waterways. The method of computing in dollars and cents their benefits is the same in principle as that for the other inland waterways, and can in practice be worked out with a much higher degree of accuracy, due to the simple and clear-cut character of the major items of traffic. The first cost to the Federal Government of these harbors and channels has been in round numbers $197,000,000. The carrying charge on this, plus maintenance, is approximately $12,000,000 a year. The gross direct freight savings to the nation amount to many million dollars a year resulting in large dividends on the investment. The enormous importance of the lakes to agriculture and basic industries cannot however be stated by a single sum such as this, since it is difficult to envisage the widespread disorganization which would follow its stoppage. If a national enemy could select one place in the continental United States to set off a carload of dynamite, with the purpose of doing the maximum damage to the nation's economic life, he might decide to explode it in the locks of the «Soo.»

G. Future of the Lakes.—The bulk commerce of the lakes has been brought to such a degree of efficiency that it is unlikely that the future will witness any striking changes save those brought about by the general development of the country. It may well be in fact, that the bulk movements will ultimately decline, due partly to the gradual exhaustion of the iron ore deposits, and partly to a greater domestic consumption of grain by our increasing population and a corresponding reduction of exports. The latter possibly is more problematical than the former.

Package freight movements on the lakes are, as stated, capable of large expansion, and it is altogether likely that the nation-wide movement for increased use of our waterways for general cargo will continue to be reflected in the lakes commerce.

Completion by Canada of the Welland Canal to a 25-foot depth will open Lake Ontario for the movement of the large carriers. This may result in the development of the Lake Ontario ports, both in the United States and in Canada, as receiving points for grain coming down the lakes, and as shipping points for coal, especially hard coal, going up the lakes, in competition with Lake Erie ports.

The traffic of the New York State Barge Canal, while considerable, is far below its potentialities, due to a variety of reasons which space does not permit the discussion of, and in spite of through rates from Lake Erie to seaboard in general lower than those of the corresponding rail lines. It is likely that with the passage of time and the working out of sound policies, this water outlet for the lakes will greatly increase in importance.

A proposal which has been advocated for many years is that of a water connection between the Atlantic Ocean and the Great Lakes, permitting ocean vessels to move direct to the lake harbors. This would have a profound effect upon the transportation situation of the lakes themselves and all the neighboring sections of the United States and Canada, and would represent perhaps the most ambitious engineering work ever undertaken by any nation. Two alternative methods have been suggested. One is for the canalization of the St. Lawrence from Lake Ontario to tidewater, commonly referred to as the St. Lawrence Waterway. This has been the subject of considerable study, and made a matter of technical investigation by an international board of engineers, American and Canadian. The proposal would also involve the ultimate development of about four and a half million horse-power of electric energy. The total estimated cost of the St. Lawrence Waterway project, including power development, is $543,429,000. The other method is by a ship canal across New York State. Several possible routes for this have been investigated by a board of Army Engineers.

The question of connecting the Great Lakes system with the Mississippi system has been discussed under «Inland Waterways» above.

III. Seaports and Harbors

The distinction between inland waterways and ports cannot be drawn rigidly. It turns on whether the harbor in question and the channel leading thereto are used primarily by vessels which traverse the open seas. In general the best criterion in doubtful cases is depth of channel, though there are numerous small fishing ports whose depths are less than those of some strictly inland waterways.

The present discussion, as in the case of inland waterways, is primarily descriptive and economic. For further data on terminals, port

organization, vessels which serve ports, and the technique of channel improvements, see HARBORS, DOCKS AND BREAKWATERS; STEAM VESSELS; DREDGE; HYDRAULIC ENGINEERING.

A. Channels.—The most important characteristic of a port channel is its depth. A large port or one of complex topography, such as New York, may have many channels, some of them adapted only to light-draft vessels. The depth of the main project channel is, however, the governing factor. The following are characteristic channel depths, and the corresponding types of traffic which they serve.

Channels in Excess of 30 Feet—These are provided at, and are needed by relatively few ports. Vessels requiring them are the very deep draft liners of the North Atlantic, whose principal terminal in the United States is New York; similar, though not so large, vessels in the trans-Pacific liner trade calling at the major Pacific ports; a few freight vessels, of which the principal examples are the largest oil tankers and certain freighters which carry iron ore from South America to New York, Philadelphia and Boston, often returning with coal. The number of these big ships is limited.

Channel Depth of About 30 Feet.—This depth, with the exceptions above given, is, at present, the usual standard for a seaport handling a general foreign and coastwise trade.

Channel Depths of 24 to 26 Feet.—Such channels are characteristic of ports having little foreign trade, or foreign trade of a class using only medium draft ships, such as the lumber trade of Central and South America, but having a large coastwise or intracoastal business. They may be called the major coastwise channels.

Channel Depths of 18 to 20 Feet.—These may be called minor coastwise channels, and are particularly adapted for the moderate sized steamers and other vessels which play an important part in the coastwise movement of lumber on the Atlantic, Gulf and Pacific.

Lesser Depths.—These are usually found in fishing harbors or in ports like the small ones on Chesapeake Bay, the commerce of which is handled by ships traversing comparatively sheltered waters.

The question of appropriate depths is a very interesting and complex one, turning as it does on the drafts of vessels in various forms of trade and on the trend of these drafts in future construction. Since the introduction of steam, vessels have in general tended to become of still deeper draft, and this tendency continues. The increase is however more noticeable and more regular in the case of the *average* vessel than in the case of the *largest* vessels.

In the case of very deep draft vessels, with the exception of oil tankers, there is apparent no decided tendency to go beyond the maximum adopted in the past decade. Vessels like the *Leviathan, Berengaria, Majestic,* etc., were constructed largely on account of commercial rivalry between different big steamship lines, or national rivalry between English and German builders before the World War. They are confined almost entirely to the so-called «Atlantic ferry.» It is generally understood that they were not paying investments. Careful cost statistics indicate that for the highest grade passenger service on the North Atlantic the typically most economic vessel has a draft of about 30 feet. The tendency in the post-war construction programs of the important Atlantic lines was toward vessels of such drafts as these and around 20,000 gross tons, instead of toward the mammoth types built just before the World War. However, two vessels exceeding 1,000 feet in length have recently been completed for Atlantic service and placed in commission.

The appropriate channel depth at any given port is of course modified by the tidal range, since if there is a large rise of tide the depth may be somewhat decreased and still permit vessels to enter by waiting a few hours for a satisfactory tide. It is also sometimes the practice to increase by 2 feet or so the channel depth over the bar at the mouth of the harbor, if difficult weather conditions are encountered there.

Widths of channels vary greatly according to the density of traffic, the danger of neighboring shoals, the curvature of the channel, and other factors. Ambrose Channel, the main approach to New York Harbor, has a width of 2,000 feet. At the other extreme, the Houston ship channel, which is practically a canal with soft bottom leading inland from Galveston Bay, has a present project width of from 250 to 400 feet. From 400 to 600 feet is usually found ample for a main approach channel in an open harbor.

B. Improvement of Harbors.—The Federal agencies for improvement of harbor channels, and the means of obtaining authorized improvements, are the same as those described under «Inland Waterways» above. For technical details of improvement, see other references. Briefly, it may be said that port improvement is achieved either by dredging to deepen channels, by jetties at harbor mouths which concentrate the tidal flow and cause it to scour a deep channel over the bar, or by breakwaters, which are protective structures built to enclose and shelter areas of a harbor or waterfront.

C. Location, Description and Functions of American Ports.—Coastwise trade is often considered as competitive with rail traffic. In general, however, a port cannot be considered as a competitor to a railroad, or even, like an inland waterway, as a complementary means of transportation. It is a necessary *supplement* to railroads, being the point at which the rail haul is extended by transshipment to water. The commercial history of American ports, therefore, is of competition not between a port and a railroad, but between different ports or groups of ports, each served by its own rail net. The commercial importance of a port is based primarily on the tributary territory which it serves as a gate of ingress and egress, principally by rail connections. Every important port is surrounded by a land area within which rail rates to or from the port are less than rail rates to or from other adjacent ports. This is its non-competitive tributary territory. Ordinarily it extends only one or two hundred miles into the interior. Beyond these lie areas which have the same rail rates to any one of a number of principal ports and in which therefore the competition by ports must be based entirely on factors other than rail rates.

There follows a classification of American salt-water ports, with channel depths and a brief description of tributary territory.

1. The Major North Atlantic Ports.—These are New York, with an approach channel of 40

feet, and numerous interior channels, some as deep as 40 feet; Philadelphia, the second salt-water port of the nation, with a project channel of 35 feet; Boston, with an approach channel of 40 feet; Portland, Me., with an approach channel of 35 feet.

New York is, and probably will always remain, the first port of the country. While immense quantities of coal, petroleum products and other bulk material move through it, largely on account of the dense population in the port district, its predominance is the most striking in the matter of miscellaneous package freight for import and export. Such freight habitually moves in less than shipload lots to or from a wide variety of overseas ports. It therefore tends to seek a port which has vessel service to all foreign ports of the world, even if this involves a long line haul and higher rail charges than would a movement to another port. In this class of material it is particularly true that «a port grows by its own growth.» With the unequaled variety of vessel service available, New York attracts to itself miscellaneous import and export business of a large part of the United States, and handles in terms of tonnage 25 per cent of all American imports and exports exclusive of those on the Great Lakes or moving by rail to and from Canada and Mexico. Its tributary territory (not of course exclusive) is a larger part of the entire country.

On rail shipments to or from points outside their limited non-competitive tributary territories and lying north of the Ohio and east of the Mississippi, the other principal northeastern ports have a differential under New York rates. A large part of the business goes to New York in spite of this, but the differential and other factors displace some of it to other points. Philadelphia, the largest of them, in addition to serving the great manufacturing area of eastern Pennsylvania, has a large tributary territory extending into the northwest. Boston's territory is principally Massachusetts, northern New York and Canada. Portland, outside of local traffic and coastwise coal receipts, is important principally as an overflow port for Canadian grain, after Montreal is closed in winter. Baltimore and Albany have a considerable hinterland of the West, and also a large traffic connected with the neighboring industrial sections.

At all these ports the question of the grain movement from the Northwest is of great importance. It fluctuates considerably. Important factors are the growing importance of Montreal; the predominance of New York for the export of grain by liners in part cargoes, as distinguished from ship-load movements in chartered or tramp vessels; the New York State Barge Canal; the deflection of grain from Boston on account of the rate situation; and the increasing demand of the ports to the south, including Norfolk, to obtain a share of the movement.

2. The New England Coastwise Ports.—This is a group principally on the southern shore of New England. The most important ones commercially are Providence, New Haven, Bridgeport, New Bedford, Fall River and New London. These principally serve the important high-grade industrial area of southern New England. Their major movements are coal and fuel oil inbound and an exchange of high grade freight with New York by the sound steamers. They are an illustration of the tendency of foreign trade to gravitate to a large port; though they have a tributary territory producing many exports and receiving many imports and though the larger sound ports have suitable depths for foreign commerce, nearly all such commerce is through New York, at which point it is transshipped to rail or coastwise steamers. Providence is, in a sense, an exception, having imports between half a million and a million tons; but most of it is petroleum products.

3. The Major South Atlantic ports.—These include Baltimore, with 37 feet; Wilmington, Del., with 30 feet; Wilmington, N. C., with 30 feet; Norfolk, Va., with 40 feet; Charleston, with 30 feet; Savannah, with 30 feet; and Jacksonville with 30 feet. In the past they have handled principally bulk commodities, and material produced or consumed east of the Appalachians, but they are making increasing efforts to take from New York and the other northern ports a larger share of the general commerce pertaining to the interior sections both south and north of the Ohio River. Norfolk and Newport News are primarily coal ports. They handle most of the coal exports of the United States, and ship many million tons in coastwise barges and ships to the northern ports. Wilmington, N. C., exports North Carolina cotton and receives fertilizer materials for local manufacture. Charleston's territory is largely limited to the Carolinas; it exports cotton and coal and receives fertilizer materials. Jacksonville is primarily a Florida port handling lumber, naval stores, and fertilizer material. Savannah, though with a harbor naturally inferior to either Charleston or Jacksonville, had, until recently, a commerce larger than either, and still handles coastwise a large tonnage in high grade material. Its major movements are inbound sugar and fertilizer materials and outbound cotton, resin and lumber, with an important general package business. All these ports in addition receive, mostly in tankers, quantities of petroleum products for interior distribution, and Charleston also ships a considerable tonnage of them.

4. The Major Gulf Ports.—These are New Orleans, with a 35-foot approach through Southwest Pass (of the Mississippi River), a 30-foot approach through South Pass, and ample depths up to the city; Galveston 35 feet and Texas City, with 33 feet; Houston, above Galveston, with 32 feet; the so-called Sabine ports, in eastern Texas, including Port Arthur, Beaumont and Orange, with depths of 30 to 35 feet in the approach channels; and Mobile, 32 feet. The leader is New Orleans, largely on account of its strategic situation near the mouth of the Mississippi, whereby it enjoys service to the interior both by the river, which contributes an important part of its commerce, and by the railroads following the general line of the river. It is the most important port of entry of vegetable food products from Gulf, Caribbean and South American points, and draws grain exports from the central and southern Mississippi basin and lumber exports from the stands in the lower Mississippi Valley. It also has an exceptionally important commerce in petroleum products. The Galveston Bay ports are the next in order on the Gulf, and their aggregate waterborne commerce in recent years has exceeded that of New Orleans.

Of the three, Galveston is primarily a shipping point for the Mississippi Valley grain and for Southern cotton, in which items it has in certain years exceeded New Orleans. Houston is most important as a cotton shipper. Both Galveston, Texas City and the lower stretches of the Houston ship channel handle a very large commerce of petroleum products, including both crude oil inbound from Mexico to be refined, and fuel oil and other products outbound.

The Sabine Ports—Port Arthur, Orange, and Beaumont—deserve a rating as first class ports on account of the great volume of their commerce, though it is principally petroleum products. They also handle some lumber. Lake Charles, in Louisiana, has been connected with this system by a 30-foot channel constructed as local expense. The remaining major Gulf port is Mobile; serving primarily the states of Mississippi and Alabama, and handling a large amount of lumber, and lesser quantities of bananas, molasses, fertilizer materials, and outbound metal products from the Birmingham district.

5. Secondary Ports—South Atlantic and Gulf.—These include Tampa, Fernandina and South Boca Grande, all important in the export of phosphate rock; Miami, a growing coastwise port; Freeport, Corpus Christi, Brownsville and Port Isabel, new ports, which promise to have an important tributary territory in southern Texas; Georgetown, S. C., Brunswick, Ga., Pensacola, Fla., Pascagoula and Gulfport, Miss., ports of varied importance.

6. Major Pacific Ports.—These include San Francisco, with 50 feet through the ocean bar and Golden Gate; Portland, Oregon, with 35 feet up the Columbia River (40 feet at the mouth); Seattle and Tacoma with almost unlimited depths; Los Angeles with 40 feet; and San Diego with 40 feet. San Francisco has long been, and still remains, the leading Pacific port of general commerce to and from the Orient, with a large tributary territory in the western United States. Its commerce is of a most varied character, outstanding items being agricultural and petroleum products outbound; lumber and metal manufactures inbound, and a heavy miscellaneous movement in both directions. Scattle and Portland probably stand next, the latter notable as a shipping point for Northwestern wheat and lumber, the former handling fuel oil, lumber and miscellaneous commerce. Tacoma has an important commerce, notably in copper and its ores and lumber. Los Angeles, in terms of tonnage, has recently outstripped them all, and indeed in 1934 was the fourth salt water port in the United States, nearly equalling Philadelphia. The greater part of its commerce is, however, outbound oil from the local fields and inbound lumber for local consumption. It has not yet developed a territorial hinterland in any way proportional to the bulk of its commerce, though ambitious plans in this direction are under way. San Diego's commerce is principally coastwise oil and lumber distributed to the neighboring territory.

7. Northwestern Lumber Ports.—This includes a number of ports on the northern California, Oregon and Washington coasts and on Puget Sound. Their depths vary considerably; in some cases natural harbors exist so deep that no channel work is necessary (e. g., Port Angeles), while at the other extreme there are ports presenting very difficult channel approaches, improvement of which is so expensive that only limited depths have been attained so far. Among the most important commercially are Grays Harbor, Everett, Bellingham, Olympia, Willapa, Coos Bay and Humboldt.

8. *Other Ports.*—Some minor harbors on the New England and New Jersey coasts, a number of small harbors on Chesapeake Bay, and a few on the Gulf, have channels ranging around 10 or 12 feet, a few greater and a few less. In general they are either primarily fishing harbors, or ports of call for small vessels moving in partly sheltered waters. They are quite numerous and require no special description, though their maintenance and success are often of vital importance to the neighboring territory and their aggregate contribution to national wealth and commerce is considerable.

D. Commerce.—The accompanying table on page 102 shows the commerce of the principal ports and groups of ports of the country. There is added another table showing the consolidated commerce for both ports and internal waterways corrected by eliminating all known duplications.

E. Design and Efficiency of Ports.—A port is a transshipment point from rail to water. It is also a storage point for inbound or outbound material held often for a considerable time while waiting transshipment. It is also frequently an important industrial centre, the products of whose industries are likely to move by the ships and railways which serve the port. It is also frequently a centre of population, the local consumption of which produces a large movement by both rail and water. Therefore the proper and efficient organization of its *purely port function,* that of transshipment, evidently requires a close coordination of the various facilities, involving not only the actual terminals but also the railroad yards and approaches, and the lay-out of the manufacturing, commercial and residential elements of the community with reference to the port facilities.

Too, often, in the past, our ports, notably those which are important cities, have concentrated their attention almost entirely on local and municipal matters, and have permitted the port facilities to grow up in a helter-skelter fashion. Several results are notable. For one thing, terminal design in many of our ports is far behind the best practice, two of the most common errors being long narrow piers with inadequate transit shed facilities, causing congestion, and the absence of adequate warehouses. For another thing, railroads have been permitted to develop, individually, sections of the harbor, and to use terminals in various ways to increase their business at the expense of other railroads, whereby the port, instead of being a single competitive unit, becomes in effect several competitive sub-ports in one locality. As a corollary to this, adequate interchange facilities between and among the various terminals and railroads, by a belt line or the equivalent, have in many cases not been developed. For another thing, there is ordinarily no adequate planning and zoning of the waterfront whereby industrial terminals, general package terminals, bulk terminals handling spe-

Commerce of Principal United States Ocean Ports, 1937

Note.—In thousands of short tons of 2,000 pounds. In addition to the commerce here shown, many of the ports have (1) commerce with ports on internal rivers and canals; (2) purely local port traffic, including in the case of New York, Philadelphia, and San Francisco, what is called intraport traffic between parts of a harbor for which separate statistics are maintained. These forms of traffic, although the aggregate tonnage is large, are of much less economic importance than foreign and coastwise traffic.

cial material (notably the kinds having a high fire risk), etc., are grouped separately. It is also a general rule, as in the case of inland waterways, that the handling of bulk material is likely to be done with a greater proportionate efficiency than that of package freight. Certain large ports are exceptions to these rules; two examples are New Orleans and San Francisco. It is notable that in both these ports a public agency owns and operates the waterfront facilities.

Either public ownership and operation, or close public control and supervision, is extremely advisable if a thoroughly systematic and economical development is to be attained.

Recent years have seen definite progress in efficient port development. Several factors have contributed to this, including the general national trend toward greater efficiency mentioned above, and the ambition of many ports to turn from the almost exclusively bulk business of former days and obtain a larger share of the higher grade package freight. The industrial growth of the South and of the Pacific Slope has had a pronounced effect. Another important factor is the policy of Congress, exemplified in the Transportation Act of 1920, to demand terminal development as a requisite to channel improvement at Federal expense. This far-reaching policy has caused many ports to devote much money and skill to the modernizing of their terminals. An important new function of the army engineers is that of consulting with and advising ports in the matter of terminal development, in order that this may be co-ordinated with channel improvement.

F. Benefits and Justification of Ports.—Under section «G» of *Inland Waterways,* page 91, it was pointed out that the Federal Government improved a river on the strictly business basis of comparing the *cost,* i.e., carrying charge on initial investment plus annual maintenance, against profits, considered as the *savings in cost of transportation on material moving via*

the channel instead of by other means. An identical policy is applied in the case of Federal port and harbor channel improvements. In its application, however, certain complications are encountered, not present with inland waterways. An inland waterway, in the great majority of cases, is an alternative to some other means of transportation, usually rail. There is thus something definite to which, in any specific case, the cost of movement on the waterway can be compared. A port is also alternative to a railroad, so to speak, in the matter of coastwise hauls; that is, freight can either go through the port and move coastwise on a ship, or move direct to destination by rail. But with overseas trade there is no alternative means of transportation; it must go by ship in any case. The value of a port in this case can be ascertained only by comparison with another port. If the question arises of establishing a new port, or improving an existing one to serve new traffic, it is necessary to study what ports the expected traffic now moves through; what it costs, by rail and vessel, under existing conditions, to carry it to origin and destination; and how much this cost would be reduced, if the traffic were deflected to the new port. There must also be considered the possible development of entirely new commerce, through the superior facilities afforded by the new port or channel. Thus are computed the benefits which are weighed against the costs. As with inland waterways, there are uncertain factors to be carefully weighed; notably the inertia of trade, its tendency to move by an existing route where all facilities are provided and all details understood and arranged for, even though a new untried route exists which promises theoretical savings. This inertia is especially notable in the case of high-grade and package freight, which as explained tends to move to ports where there is liner service to numerous points. A new port usually starts its life principally with bulk movements of a few commodities in tramp or chartered bottoms, and the building up of a liner service and general cargo traffic is a slow process.

The rates by ocean vessels are usually «blanketed,» i.e., the same for similar commodities, for large groups of ports of both origin and destination. Therefore the differentials by which a port shows savings over another port are usually rail differentials.* As stated, an important port usually has a tributary area within which rail rates to it are less than to neighboring ports, and it is within this area that the «differential savings» computations apply. For the more remote hinterland, where rail rates are blanketed to a number of ports, no such savings can be computed.

The computation of «differential savings» is applicable to practically all *proposed new* projects for port development.

When, however, we try to apply to ports *in being,* to evaluate them, the method is not universally applicable. It would seem that we could take any given port, and, knowing the origin, destination and cost of movement of freight moving through it, could assume all this diverted to another port, and figure out how much more it would cost to move it. This is theoretically practicable, though very laborious, and though the question of what other port or ports to select may be difficult to decide. But there are cases where the computations would show no savings at all, but a loss. A large part of the trade that moves through New York could, *so far as rail rates go,* get to shipside more cheaply through other ports. But it continues to use New York: Because it is used to it; because of the great consuming capacity of the port district; because New York can furnish sailings to almost any port in the world; because New York is the financial and business center of the nation, and a great warehousing and distributing centre. Similar examples could be cited elsewhere.

These remarks are of special interest to one seeking to evaluate the transportation function of our ports as a whole. This can be done in theory, and approximated in practice, for inland waterways. It cannot be done for our ports even theoretically. If all our inland waterways were closed up, great disorganization would ensue, but given the money to build enough new railroads, it would still be possible to move the traffic. But if all our ports were closed up, our foreign trade would cease, with economic consequences impossible to predict.

It is, however, theoretically possible to evaluate our ports as a whole from the standpoint of *coastwise and intercoastal trade only,* for this at least could move by rail—given the railroads—if the ports were not there, and therefore rate differentials can be obtained.

On a different basis, the investment has made possible the collection of custom duties of about half a billion dollars a year.

G. Future of Our Ports.—The future of existing ports lies largely in the direction of more efficient terminals; better warehousing; a better co-ordination of rail and water movements; a more careful planning and zoning of the port area; and a closer municipal control of port activities, to eliminate wasteful intra-port competition. Ports which have specialized in low-grade bulk commodities, or in the serving of a small tributary area, or both, are reaching out for trade into more remote sections, and seeking higher grade traffic, and the liner service on which this depends. In recent years there have been notable strides in efficient port planning and terminal design and construction. Certain ports, as they grow, will need deeper water; but the importance of very deep channels is often much exaggerated. It is frequently the case with ports, as with rivers, that a community expects trade to appear magically on the provision of a deep channel; which is much as if a man should build a railroad track, and then expect trains to come from somewhere and run over it. An adequate channel is one essential to a port; but there are many other essentials. And as shown above, much of the world's commerce moves on very moderate drafts.

In the near future it is unlikely that there will be many entirely new ports of importance developed in this country. Most of the existing ones are not being used to capacity, or if they are, it is because the port lay-out and terminals are not of the highest efficiency. And a glance at our coast-line will show that there are few long stretches of coast, with important

*Also, theoretically, differentials on terminal charges. This is important in port competition, if the terminal charges are assessed in toto against the shipper. But where terminals are rail-owned, all or part of the terminal charge is often absorbed into the line-haul rate.

and productive hinterlands, where a port does not exist which is capable, perhaps with a little expansion and channel deepening, of serving the tributary territory economically. A few new ones may develop. In the main, however, the future lies with the existing ports, working toward better organization, more efficient service and greater diversification of trade.

Beach Erosion.—Closely allied with problems for the improvement of coastal and Great Lakes harbors is the question of stabilizing outer exposed shores, especially at localities such as bathing and recreational beaches where, in many instances, great damage may result to the shores from storm and wave action, and be highly detrimental, through drift of material, to the permanency of channel entrances. Congress has recognized the importance of undertaking measures to regulate and control the forces affecting the permanency of coastal beaches and shores and in the River and Harbor Act of 3 July 1930, authorized and directed the Chief of Engineers of the United States Army, under the direction of the Secretary of War, to cause investigations and studies to be made in co-operation with appropriate agencies of various States on the Atlantic, Pacific, and Gulf coasts, and on the Great Lakes, and the Territories, with a view to devising effective means of preventing erosion of the shores of coastal and lake waters. The act provided for the organization of a board of seven members, of whom four members are officers of the Corps of Engineers while three members are selected from among State agencies co-operating with the War Department. This board is known as the Beach Erosion Board. At the same time that the Beach Erosion Board was created a similar organization, designated as the Shore Protection Board, was also appointed, this latter board being composed of the Army Engineer members on the Beach Erosion Board, the primary function of the Shore Protection Board being to confine its studies to problems of erosion affecting Federal property only. Furthermore, Congress by Act of 26 June 1936, directed that investigations be made to determine methods of beach protection and restoration; that States, counties, municipalities, or individuals, be advised of appropriate locations for recreational facilities; and that data and information which the Beach Erosion Board may deem will be of value to the people of the United States be published from time to time. The amendment further provided that, in reporting on the advisability of adopting a project, the board shall determine the extent of the Federal interest therein and the share of the expenses, if any, which should be borne by the United States. State agencies desiring co-operative studies and investigation by the Beach Erosion Board may inaugurate such an investigation by applying either direct to the Chief of Engineers, U. S. Army, Washington, D. C., or through the U. S. District Engineer having jurisdiction in the locality affected. In general terms, an application for co-operation should show the authority of the agency under the laws of the State to conduct studies and investigations, and the extent which the locality is willing to co-operate with the Federal Government. Since its creation, the Beach Erosion Board has conducted co-operative studies of shore erosion including the preparation of plans for co-operative measures at localities in the States of Massachusetts, New York, Delaware, New Jersey, North Carolina, Florida, Louisiana, Michigan and California.

Bibliography.—*Official Publications.*—The 'Annual Report' of the Chief of Engineers, U. S. Army, is the original source of official data respecting the progress of improvements adopted by Congress. Part 2 of this report gives the only complete annual consolidation of data relative to the tonnage and value of the commerce of our ports and waterways. The individual projects are based upon reports on examinations and surveys, published separately as Congressional documents. Detailed information regarding the Great Lakes and connecting channels is contained in the 'Survey of Northern and Northwestern Lakes,' published by the United States Lake Survey Office, Detroit, Michigan, which office also issues charts of the channels and harbors of the United States. Other important official publications are as follows:

War Department, Corps of Engineers.—Port Series, consisting of some 37 volumes covering our major ports; *Transportation Series,* consisting of four volumes, two of which deal with the Great Lakes and two with the Mississippi River System; *Lake Series,* consisting of eight volumes covering ten of the important Great Lakes ports; Miscellaneous Series, Nos. 1 and 2 of which deal with charges at United States ports, while No. 3 is a special report on Foreign Trade Zones or Free Ports; Water Terminal and Transfer Facilities, published as House Document No. 652, 66th Congress, 2nd Session; Water Terminal and Transfer Facilities, published as House Document No. 109, 67th Congress, 1st Session; Experimental Towboats, published as House Documents Nos. 857, 63rd Congress, 2nd Session, and 108, 67th Congress, 1st Session.

Certain other official publications.—Annual reports of the Inland Waterways Corporation, War Department; Statistical Abstract of the United States, published annually by the Department of Commerce; reports on Transportation by Water in the United States, published in 1906, 1916, and 1926 by the Department of Commerce; Inland Waterway Freight Transportation Lines in the U. S., published by Department of Commerce in 1930; report of the Commissioner of Corporations on Transportation by Water in the United States in four volumes, published in 1909–10; Preliminary report of the Inland Waterways Commission, published in 1908 as Senate Document No. 325, 60th Congress, 1st Session; Preliminary and Final Reports of the National Waterways Commission, Senate Documents No. 301, 61st Congress, Second Session and No. 469, 62nd Congress, 2nd Session.

R. W. Chaffee,
Principal Engineer,
Office, Chief of Engineers,
United States Army.

WATERWORKS, systems of machinery and engineering structures, employed to supply water to individual manufacturing, mining and milling plants, and to municipalities, for domestic and industrial uses and for irrigation. Such systems existed during very early periods of history, and the waterworks of ancient Greece, Carthage and Rome may be readily traced and studied by the ruins of their reservoirs and

masonry aqueducts. In these earlier systems, gravity was depended upon for the delivery of the water, but force pumps were introduced about the middle of the 16th century, and extended greatly the general installation and use of waterworks systems. The waterworks built at London Bridge by Peter Maurice 1562 appear to be the first on record. The plant consisted of 16 force pumps, each 17 inches in diameter, and 30 inches long, which were driven by a current wheel, and raised 311,000 gallons of water per day to a reservoir at an elevation of 120 feet above the pumps, and from which the water was delivered by gravity, through lead pipes to buildings in the immediate vicinity.

In the United States, the first pumping plant installed to provide water for municipal purposes was that at Bethlehem, Pa., about 1760. It consisted of a five-inch wooden force pump, which raised water to a height of 70 feet through pipes of bored hemlock logs. This was replaced in 1761 by three single-acting iron pumps, each four inches in diameter, and of 18-inch stroke, operated by an undershot waterwheel. The first municipal water-supply system built in America, however, was that of Boston, in 1652. It was built by the Water-Works Company, and consisted of a reservoir about 12 feet square, to which the water from springs in the vicinity was conveyed through wooden pipes. From 1652 up to the close of the year 1800, the waterworks plants in the United States numbered 16, and had been located and built at the following named cities: Boston, Mass., 1652; Bethlehem, Pa., 1754–61; Providence, R. I., 1772; Geneva, N. Y., 1787; Plymouth, Mass., 1796; Salem, Mass., 1795; Hartford, Conn., 1797; Portsmouth, N. H., 1798; Worcester, Mass., 1798; Albany, N. Y., 1798–99; Peabody, Mass., 1799; New York City, 1799; Morristown, N. J., 1799; Lynchburg, Va., 1799; Winchester, Va., 1799–1800; and Newark, N. J., 1800. With the exception of the plants at Winchester and Morristown, they were all built by private concerns, but passed into the ownership of the respective municipalities from time to time up to 1860. The works at Winchester were built by the municipality, and those at Morristown were built by a private concern and still remain in private ownership.

A clear and concise consideration of the subject of waterworks may be facilitated by arranging the various requirements under the four general headings—quality of the water; sources of supply; modes of distribution, and public policy.

Quality expresses the fitness of the water for the special purposes for which it may be required. A good quality of water is characterized by freedom from turbidity and color, unpleasant taste and odor, and undue sewage contamination.

Taste is the first quality to be satisfied in drinking water. Even a perfectly safe water may be rejected because of nauseating flavor. This may often be remedied by dosing with chlorine and then removing the chlorine taste with sodium sulphite.

Turbidity is a condition caused by clay and silt suspended in the water. When the source of supply is a river, this condition is liable to great variation according to the amount and character of the rainfall over the watershed. Heavy rains of short duration are drained off with great erosive effect, and introduce into the flowing rivers vast quantities of finely divided inorganic matter. Such impurity, however, is more offensive than harmful, unless taken into the system frequently or in large quantities. It is removed by the use of settling reservoirs where the water is allowed to rest and deposit the heavier particles, before it is passed through the filter-beds by which the smaller particles are removed. (See WATER SUPPLY). Color is a condition more offensive to the eye than harmful to the health. The apparent color due to turbidity disappears under the processes of sedimentation and filtration, but true color, generally due to infusion of vegetable organic matter, such as leaves, grass, etc., is much more difficult to remove.

Odor is a condition which, although less frequent, is much more objectionable than turbidity or color. As a rule it is due to the life processes of minute organisms, and is removable to a considerable degree by filtration. It may, however, persist at certain times in the year and has been known to produce, or be followed by bowel disturbances among small children.

Sewage contamination is the most harmful of all the various forms of impurities natural or artificial that a water supply may be subjected to, and is the direct cause of epidemics of typhoid fever and various troubles of the intestines, which by undermining the constitution reduces its power of resistance to other diseases. The water may be somewhat purified by filtration, but the proper remedy is to remove the source of pollution. Failing this, even a much polluted water may be made reasonably safe for drinking by sterilization with chlorine.

The quality of water is ascertained by various kinds of analyses, physical, chemical and bacteriological. Physical analyses consist merely of comparisons of the given samples with standard solutions, and afford data relative to temperature, turbidity, color and odor. Chemical analyses indicate the time of past contamination and the nature of its origin—animal or vegetable, and the content of mineral salts. Bacteriological analyses are principally used to ascertain the absence or presence of the growths which cause bad taste and odor. Such analyses are capable of showing the number and probable origin of the bacteria present, but in matters of differentiation, as in the case of the typhoid germ from the harmless water bacteria, their operation is quite uncertain.

The results obtained by any set of analyses are generally interpreted by chemists and engineers by comparing them with other known facts, without attempting to establish a system of arbitrary standards. A minimum limit of impurity, however, may be stated, as follows:

(1) The best authorities consider water as unfit for drinking purposes when 100,000 parts of the liquid contain more than three parts by weight of mineral matter or one part by weight of dry organic matter, before it has been submitted to precipitation, or when it holds in suspension more than one part by weight of dry organic matter after six hours of perfect repose in a reservoir.

(2) When the same amount of liquid contains in solution more than two parts by weight of organic carbon, or three parts of nitrates.

(3) If it exhibits a distinct color under day-

light when placed in a white porcelain dish, to the depth of one inch.

(4) When 100,000 parts of the liquid contain more than two parts by weight of a salt of any metal except calcium, magnesium, potassium and sodium.

(5) When 100,000 parts of the liquid contain in solution, suspension, or chemical combination, more than 0.5 part of arsenic.

(6) When 100,000 parts of the liquid, after the addition of sulphuric acid, contain more than one part by weight of free chlorine.

(7) When 100,000 parts contain more than one part by weight of sulphur in the form of sulphuretted hydrogen, or a soluble sulphuret.

(8) When 100,000 parts of the liquid holds in suspension more than 0.5 part of petroleum or hydrocarbon, or exhibits a film of the same upon its surface.

(9) When the acidity is greater than that produced by two parts by weight of hydrochloric acid to 1,000 parts of distilled water.

(10) When the alkalinity is greater than that produced by adding one part by weight of caustic soda to 1,000 parts of distilled water.

(11) When 10 cubic centimeters of water contain more than 100 harmless bacteria. This is the requirement of the government for water served on railroad trains in interstate commerce, and is adopted by all bottlers of table waters.

In general, a large percentage of chlorine and nitrates, together with the presence of *Bacillus coli communis,* an organism originating in large quantities in the human intestines, indicate sewage contamination.

A very simple but reliable test for sewage contamination was suggested by Heisch. To half a pint of the suspected water placed in a clear colorless glass-stoppered bottle, add a few grains of the best white lump-sugar, and expose the bottle freely to daylight in the window of a warm room for a week or 10 days. If the water remains clear it may be considered safe, but if it become turbid, it is open to grave suspicion of sewage contamination.

Turbidity or a precipitate which follows upon the addition of baryta water indicates the presence of carbonic acid; chloride of barium is used in the same way as a test for sulphates; nitrate of silver for chlorides; oxalate of ammonia for lime salts; sulphide of hydrogen, slightly acid, for salts of antimony, arsenic, bismuth, calcium, copper, gold, lead, mercury, platinum, silver and tin; an alkaline (by ammonia) solution of sulphide of ammonium, for salts of aluminum, chromium, cobalt, iron, manganese, nickel, and zinc. Chloride of gold or mercury and the sulphate of zinc are the reagents for organic matter.

Hardness of water is a quality that bears chiefly upon its use for boilers and for laundry purposes. The hardening impurities are principally the salts of lime and magnesia. Their carbonates produce temporary hardness which may be removed by boiling, when the carbonic acid is dissipated and the insoluble bases are deposited as incrustations on the bottoms of the kettles and boilers. The carbonates are less troublesome to the human constitution than to steam users, but the sulphates, chlorides and nitrates of lime cannot be dissipated by ordinary boiling and are productive of what is known as permanent hardness. Ordinarily pure water can take up only about two grains of carbonate of lime per imperial gallon of 70,000 grains, but when carbonic acid is present, that amount of water will dissolve as much as 20 grains of the carbonate. The degree of hardness is estimater according to the number of grains of soap the solution is capable of neutralizing. Thus, one, two and three degrees of hardness represent the neutralization of 10, 20 and 30 grains of soap, respectively. The amount of waste, in the wear of clothes and soap, and the destruction of many valuable food properties by the use of hard water is not fully appreciated by the general public. It is safe to state that the money value of that waste far exceeds the cost that would supply an abundance of water for domestic purposes from a source free from impurities.

Systematic processes for softening water have been employed in the United States, principally in connection with manufacturing plants. The first process was invented by Prof. Thomas Clark, of Aberdeen, Scotland, in 1841, and consists of mixing the water supply with lime water or milk of lime, and allowing it to subside for a period ranging from 12 to 24 hours, when the water is drawn off while the precipitate is left behind. The first softening plant in connection with a municipal water supply in America is that connected with the waterworks of the city of Winnipeg, Manitoba. The source of supply is a number of artesian wells, and the water obtained is very hard. The softening process employed is a modification of that of Clark, and includes a variety of settling and filtering devices, into which the water is pumped and mixed with the lime solutions and then drawn off and distributed by direct pressure pumping into the mains. Its working provides a water more beneficial to the health, and better for domestic purposes, than that of the Red River, which formed the original water supply of the city. (See WATER SOFTENING).

While boiling is a very cheap and thoroughly effective process of purifying water, and may be used by householders in general, distillation, owing to its expense, may be employed only in special cases, in connection with artificial ice plants, the conversion of salt water into fresh water at sea, and in the various industrial arts.

Waste by leakage from the mains and poorly constructed flushing devices varies from five gallons upward per capita, and its reduction to a minimum is essential to the economical operation of any system of waterworks, but it is especially important when the service is by pumping, for the cost of pumping the waste is proportionally equal to that which is actually used. This is true also when the source of supply is distant and the purity of the water depends upon the conservation of its quantity. This can only be accomplished by careful workmanship in the construction of the plant; careful pipe laying; the use of high-grade, self-closing plumbing fixtures, especially those devices used for flushing water-closets and the installation of meters not only to detect leaks and other causes of waste in the houses, but to form the basis for charges against the consumer and compel carefulness on his part. This, however, brings the matter to a point where it is necessary to harmonize good practice with

public policy. The details of district meter systems and the inspection of service pipes are minor problems as compared with the equitable adjustment of water rates according to the various classes of consumers. In general, although the district plan is but a poor competitor of the house meter system, it has produced good results in controlling waste and detecting leaks whenever it has been employed. See also HYDRAULICS; HYDROSTATICS.

L., *Public Water Supplies,* 3d ed. (New York 1925); Williams and Wilkins, *American Waterworks Practice,* American Waterworks Association (Baltimore 1925); Maxwell, W. H., *Water Supply Problems* (New York 1934); Folwell, A. P., *Manual of Water Works Equipment* (New York 1936).

WATIE, Stand, Cherokee Indian leader and soldier: b. Oo-yoo-ge-lo-gi, near the site of Rome, Ga., Dec. 12, 1806; d. Sept. 9, 1871. His father, David Oowatie (Uweti), was a Cherokee of pure Indian blood and his mother was the child of a white father and a Cherokee mother. His given name was Degataga, which, rendered into English, signified "standing together," whence came his English given name, Stand. His surname was a contraction of his father's given name. Elias Boudinot, known also as Buck Watie, was an elder brother of Stand Watie. Major Ridge was his uncle. In common with his immediate kinsmen, Stand Watie was active in his support of the removal treaty and was marked for assassination at the same time they were, but was warned in time to save himself. He was thenceforth regarded as the head of the Ridge, or Treaty Party, in the Cherokee Nation. At the outbreak of the Civil War, he espoused the cause of the seceding states, raised a regiment for the Confederate service, commanding it with the rank of colonel until May 1864, when he was promoted to the grade of brigadier general. After the close of the war he engaged in various business enterprises.

WATKIN, wŏt'kĭn, SIR **Edward William,** English railway promoter: b. Salford, Lancashire, England, Sept. 26, 1819; d. Northenden, Cheshire, April 13, 1901. He was engaged in the warehouse of his father, a London merchant, from 1829–1845, when he became secretary to the Trent Valley Railway Company, and thenceforward continued in the railway business, becoming general manager and director in various leading companies. He was chairman of the South Eastern in 1866 and of the Metropolitan in 1872, extricating each from financial difficulties. While president of the Grand Trunk Railway of Canada he prosecuted negotiations which resulted in the confederation of the five British North American provinces. He was elected to Parliament for Great Yarmouth in 1857, but was unseated by petition. In 1864–1868 he was a member for Stockport, and for Hythe in 1874–1895. He was knighted in 1868, and created a baronet in 1880.

WATKINS, wŏt'kĭnz, **John Elfreth,** American scientist: b. Ben Lomond, Va., May 17, 1852; d. New York, New York, Aug. 11, 1903. He graduated from Lafayette College in 1871, and for a year was mining engineer for the Delaware and Hudson Canal Company. In 1872–1873 he was engineer of construction for the Pennsylvania Railroad until he lost one leg in an accident. From 1874 to 1886 he was chief clerk of the railroad. He was appointed curator of the United States National Museum in 1886, holding this office until 1892. As superintendent and curator he built a noteworthy technological collection pertaining to the transportation industry.

He wrote much about the growth of railroad and telegraph systems, including *The Evolution of the Railway Passenger Car* (1888); *History of the Pennsylvania Railroad, 1845–96* (never published).

WATKINS GLEN, village, New York, and Schuyler County seat; altitude 477 feet; on the New York Central and Pennsylvania railroads, and two state highways; 18 miles north of Elmira, at the south end of Seneca Lake. It is in an agricultural region from which grapes are shipped and grape juice is manufactured. There are two plants which make salt by evaporating brine.

The main entrance to the park and ravine of Watkins Glen is on the village main street. The first settlers came here from Connecticut in 1788 and called the place Salubria. It was incorporated in 1842 as Jefferson; but in 1852 was renamed Watkins for Dr. Samuel Watkins, an early settler who had laid out and mapped the village. The present name dates from 1926. The electric light and power plants are public. Government is by mayor and council. Pop. (1940) 2,913; (1950) 3,052.

WATKINS GLEN, ravine, in New York, partly in Watkins Glen Village, Schuyler County, traversed by Glen Greek. It is noted for its picturesque scenery and its great beauty. It was privately owned until 1906 when it became a state park reservation. Since then additional acreage has been purchased and the total area is now 540 acres. The rock formation of the district is Devonian shale cut into narrow gorges by glaciation during the Pleistocene period. At Watkins Glen cliffs rise 200 feet above the stream which drops 700 feet in a series of cascades and rapids along its two-mile route through the gorge.

WATLALA or **WATLALLA INDIANS,** wät-lä'lä, a tribe of the Chinookan stock of North American Indians, who call themselves Kwikwulit, and who have also been known as Wahclellah, Dog River, or Cascade Indians. They formerly occupied the Cascades and about the Dog River, which discharges into the Columbia about midway between the Cascades and The Dalles, in Wasco County, Oregon. They numbered but 80 souls in 1854; in the next year they entered into the Wasco Treaty, by which they agreed to move to the Warm Springs Reservation, where a few of them now are, while the others are still about the Cascades. Their language is almost identical with that of the Wasco Indians.

WATLING STREET, wŏt'lĭng, one of the great Roman roads, starting at London, England, and going past St. Albans to Wroxeter near Shrewsbury, thence to Chester. A branch went to Lincoln and Leicester. Traces of the road are still found, and some are used; a street in London retains its name. It was the line of division in the Treaty of 878 between Alfred and Guthrum the Dane, and is today the boundary between Warwickshire and Leicestershire.

After the Conquest, Watling Street was on

a list of four royal roads recorded by Norman lawyers. Icknield and Ermine streets, and Fosse Way were the other roads, and charters name them as boundaries. In the Elizabethan period the custom began of giving the name Watling Street to many old roads which either were Roman or were thought to be so in various parts of Britain. This was the case with the road from York north to the Wall of Pius, and with the road from Dover to London.

Of the origin of Watling nothing is now known; it was once written Waeclinga Straet, and may be a corruption of Stratum Vitellianum; a hint of the title survives in the name Wattlesborough, on Watling Street near Wroxeter.

WATLINGS ISLAND. See SAN SALVADOR, island, Bahama Islands.

WATMOUGH, James, United States naval officer: b. Whitemarsh, Pa., July 30, 1822; d. Washington, D.C., Jan. 18, 1917. He was educated at the University of Pennsylvania, and from 1843–1844 was acting midshipman. He served in the Mexican War, and participated in the capture of California. In the Civil War he commanded the South Atlantic Squadron and took an active part in the operations on Stono River and James and John islands. Later he became general pay inspector of the navy, and from 1873–1877 was paymaster general. In 1884 he was retired and in 1906 was created rear admiral.

WATONGA, wȧ-tŏng'gȧ, city, Oklahoma, and Blaine County seat; altitude 1,460 feet; on the Chicago, Rock Island and Pacific Railroad; 50 miles southwest of Enid. It is in an agricultural and stock-raising region. There are grain and lumber mills, cotton gins, and poultry packing plants. Other manufactures are dairy products, gypsum products, and bedding. Located on the Chisholm Trail, Watonga was settled in 1892, and incorporated in 1893. Pop. (1940) 2,828; (1950) 3,249.

WATROUS, wô'trŭs, **Harry Willson,** American artist: b. San Francisco, Calif., Sept. 17, 1857; d. New York, N. Y., May 9, 1940. After attending private schools in New York he went to Paris and studied art at the Académie Jullian and Atelier Bonnât, becoming a pupil of Boulanger, Lefebvre, and Bonnât. Later he established himself in New York City and spent much time painting intimate scenes of city life. His Paris paintings show meticulous attention to detail, a quality which he abandoned for a time after his return to America, when he turned to figure studies and landscapes. Most of his paintings are of small size, exquisitely finished and occasionally of somewhat unconventional conception. He received many awards and prizes for his work. He was secretary of the National Academy of Design, 1898–1920, and president in 1933. He belonged to the Art Commission Associates of the City of New York, and was president of the Louis Comfort Tiffany Foundation. He married Elizabeth Nichols, also an artist, in 1887. Among his works are *Passing of Summer* (Metropolitan Museum, New York) and *A Study in Black* (St. Louis Museum).

WATSEKA, wŏt-sē'kȧ, city, Illinois, and Iroquois County seat; altitude 634 feet; on the Chicago and Eastern Illinois, and the Toledo, Peoria and Western railroads; on the Iroquois River; 78 miles south of Chicago. It is in an agricultural and stock-raising region. Soft drinks, dairy products, and batteries are manufactured. The city was laid out in 1860 on the site of a trading post and named South Middleport. In 1865 it was renamed for Watch-e-kee, Indian wife of G. Hubbard, first white settler of the region. Incorporation was in 1867. Pop. (1940) 3,744; (1950) 4,235.

WATSON, wŏt's'n, **Alfred Augustin,** American Protestant Episcopal bishop: b. New York, N. Y., Aug. 21, 1818; d. April 21, 1905. He was graduated from the University of the City of New York in 1837, studied law and in 1841 was licensed to practice in the New York State Supreme Court. He then turned his attention to theology, and in 1845 took priest's orders in the Episcopal Church. During the Civil War he served as chaplain in the Confederate Army, and in 1884 was consecrated bishop of East Carolina.

WATSON, David Thompson, American lawyer: b. Washington County, Pa., Jan. 2, 1844; d. Atlantic City, N. J., Feb. 24, 1916. He graduated from Washington College in 1864, studied law two years at Harvard, was admitted to the bar, and practiced law in Pennsylvania. In 1903 he was one of three United States' Counsels before the Alaskan Boundary Commission.

WATSON, Elkanah, American businessman and agriculturist: b. Plymouth, Mass., Jan. 22, 1758; d. Port Kent, N. Y., Dec. 5, 1842. He was apprenticed at 15 to John Brown of Providence, R. I., founder of the famous mercantile firm, and when 19 was entrusted by him with $50,000 to be invested in cargoes for the markets of Europe. He made the journey to Charleston, S. C., successfully and his journal, subsequently published, is the best existing account of the principal towns of the colonies at the time of the American Revolution. He opened a branch house in Nantes, France, in 1779, meeting with much success for three years, when he lost his property through the crash of French finances. He returned to America in 1784, engaged in trade between South Carolina and Haiti until 1788, and in 1789 removed to Albany, where he was an active promoter of public enterprises. He projected an internal canal for New York State, founded the Bank of Albany, organized the first agricultural society in New York, aided the establishment of western stage routes, and was an earnest worker for improved educational advantages. He also sponsored the first county fair in the United States. He removed to Port Kent on Lake Champlain in 1828.

He published *Tour in Holland* (1790); *History of the Rise and Progress, and Existing Condition of the Western Canals in the State of New York* (1820); *History of Agricultural Societies on the Modern Berkshire System* (1820).

Consult Watson, Winslow C., *Men and Times of the Revolution; or Memoirs of Elkanah Watson* (1856).

WATSON, George Lennox, English naval architect: b. Glasgow, Scotland, Oct. 30, 1851; d. there, Nov. 12, 1904. After a five-year connection (1867–1871) with leading shipbuilding firms in Scotland, he established himself

in Glasgow in 1872 as a naval architect. His first success was made in 1873 with the racing yacht *Clotilde*. Subsequently he designed more than 400 vessels, including, besides racing yachts, passenger, mail and cargo steamers, and some of the largest steam yachts afloat. Among his racing yachts were *Vanduara* (for John Clark of Paisley); the cutter *Britannia* (for the prince of Wales, later Edward VII), and the *Thistle, Valkyrie II,* and *Valkyrie III,* competitor's for the *America's* cup.

WATSON, Henry Brereton Marriott, English novelist: b. Melbourne, Australia, Dec. 20, 1863; d. London, Oct. 30, 1921. Graduated from Canterbury College (Christchurch) in 1883, he went in 1885 to England, where he took up journalism in 1887. He wrote much for the *National Observer* and was assistant editor of *Black and White* and the *Pall-Mall Gazette.* Among his works are *Marahuna* (1888); *The Web of the Spider* (1891); *The Adventurers* (1898); *The Skirts of Happy Chance* (1901); *The House Divided* (1901); *Godfrey Merivale* (1902); *Alarums and Excursions* (1903); *At a Venture* (1911); *Chapman's Wares* (1915); *The Pester Finger* (1919). With J. M. Barrie he was joint author of the drama *Richard Savage.*

WATSON, James Craig, American astronomer: b. Fingal, Ontario, Jan. 28, 1838; d. Madison, Wis., Nov. 22, 1880. He was graduated from the University of Michigan in 1857, was appointed professor of astronomy there in 1859, and in 1879 accepted the chair of astronomy at the University of Wisconsin. He accompanied the eclipse expeditions to Iowa in 1869 and to Sicily in 1870, and was in charge of the expedition to Peking, China, for the observation of the transit of Venus in 1874. He was the discoverer of 23 asteroids, and of several comets, receiving the Lanlade Medal from the Paris Academy in 1870 for the discovery of six asteroids in one year. In 1867 he was elected to the National Academy of Sciences, an institution to which he bequeathed $16,000 for a research fund and the Watson Medal. He published *Popular Treatise on Comets* (1861); *Theoretical Astronomy* (1868); *Tables for Calculation of Simple and Compound Interest and Discount* (1879), etc.

WATSON, John, Canadian philosopher: b. Glasgow, Scotland, Feb. 25, 1847; d. Jan. 26, 1939. He was graduated from Glasgow University in 1872 and that year became professor of mental and moral philosophy at Queen's University, Kingston, Ontario (later emeritus professor). He wrote *Kant and His English Critics* (1881); *Schelling's Transcendental Idealism* (1882); *The Philosophy of Kant as Contained in Extracts from His Own Writings* (1888); *Comte, Mill and Spencer, An Outline of Philosophy* (1895); *Hedonistic Theories, from Aristippus to Spencer* (1895); *Christianity and Idealism* (1896); *An Outline of Philosophy with Notes Historical and Critical* (1898); *Philosophy of Kant Explained* (1908); *Interpretation of Religious Experience* (1913); *The State in Peace and War* (1919).

WATSON, John (Ian Maclaren), English Presbyterian clergyman and author: b. Manningtree, Essex, Nov. 3, 1850; d. Mount Pleasant, Iowa, May 6, 1907. He was educated at Edinburgh University, New College (Edinburgh), and the University of Tübingen, was licensed to preach by the Free Church of Scotland in 1874 and appointed assistant minister of the Barclay Church, Edinburgh. In 1875 he was ordained minister of Logiealmond (Perthshire) Free Church, whence he went in 1877 to Free Saint Matthew's, Glasgow, and in 1880 to the Sefton Park Presbyterian Church of Liverpool. He was Lyman Beecher lecturer at Yale in 1896, and in 1900 moderator of the Synod of the Presbyterian Church of England. Among his religious works are *The Upper Room* (1896); *The Potter's Wheel* (1898); and *The Life of the Master* (1901). He also published several works of fiction, beginning with *Beside the Bonnie Brier Bush* (1894), a very successful collection of sketches of life and character in Highland and semi-Highland parishes, and including further *The Days of Auld Lang Syne* (1895), *Kate Carnegie* (1896), *A Doctor of the Old School* (1897), *Afterwards* (1898) and *Rabbi Saunderson* (1898); *Life of the Master* (1901); *Inspiration of Our Faith* (1905); *Children of the Resurrection* (1912).

WATSON, John Broadus, American psychologist: b. Greenville, S. C., Jan. 9, 1878. He was graduated at Furman University in 1900, and took his Ph.D. at the University of Chicago in 1903. He was assistant and instructor in psychology at Chicago in 1903–1908; and 1908–1920 occupied the chair of experimental and comparative psychology at Johns Hopkins University and was also director of the psychological laboratory there. He was commissioned major in the aviation section of the Signal Corps of the United States Reserves in 1917. He is now vice president of William Esty & Co., New York. He was editor of the *Psychological Review* 1908–1915 and from 1915 to 1927 editor of the *Journal of Experimental Psychology;* and joint editor of *The Journal of Animal Behavior.* Author of *Animal Education* (1903); *Behavior* (1914); *Behaviorism* (1925); *Ways of Behaviorism* (1928).

WATSON, John Crittenden, U.S. naval officer: b. Frankfort, Ky., Aug. 24, 1842; d. Washington, D.C., Dec. 14, 1923. He was graduated from the United States Naval Academy, 1860; promoted master in 1861 and assigned to the *Sabine.* He was transferred to the *Hartford,* flagship of Admiral David Farragut, in 1862 and served under him throughout the war. He participated in the battles of Fort Jackson and Saint Philip, served in the passage of the Vicksburg batteries in 1862, of Fort Hudson in 1863 and was engaged at Mobile Bay in 1864. He received rank as lieutenant commander in 1866, as commander in 1874 and in 1877–1880 was in command of the *Wyoming.* He was lighthouse inspector in 1880–1886, promoted captain in 1887 and commodore in 1897. In the Spanish-American War of 1898 he commanded the blockading squadron on the northern coast of Cuba, was transferred to the command of the *Oregon* later in that year and in 1899 succeeded Admiral Dewey in charge of the Asiatic squadron at Manila, with rank of rear admiral. In 1900–1902 he was president of the naval examining board and thereafter was president of the examining and retiring board. He retired in 1904.

WATSON, John Fanning, American antiquary: b. Batsto, N. J., 1780; d. Germantown, Pa., 23 Dec. 1860. He was a bookseller in Philadelphia for many years and made a careful study of early and Revolutionary history. His publications include 'Annals of Philadelphia' (1830); 'Historic Tales of the Olden Times in New York' (1832); 'Annals of New York City and State' (1846); 'History of the United States' (1856).

WATSON, Musgrave Lewthwaite, English sculptor: b. Hawkdale, Cumberland, near Carlisle, 1804; d. London, 28 Oct. 1847. Meeting Flaxman in London in 1823 he gained the friendship of that sculptor, through whose influence he was admitted to the schools of the Royal Academy. He subsequently visited Rome, working under Chantrey (q.v.) and Behnes. His productions include a terra cotta relief, 'Suffer Little Children to Come Unto Me'; and statues of Flaxman, Nelson, Chaucer and Queen Elizabeth.

WATSON, Paul Barron, American author: b. Morristown, N. J., 25 March 1861. He was graduated from Harvard in 1881, subsequently studied law and was admitted to the bar and has practised in Boston. His published writings are a 'Bibliography of the Pre-Columbian Discoveries of America,' privately printed in 1881, and included in the fourth (enlarged) edition of 'America Not Discovered by Columbus,' by R. B. Anderson (q.v.); 'Marcus Aurelius Antoninus' (1884); 'The Swedish Revolution under Gustavus Vasa' (1889); and 'Tales of Normandie' (1930).

WATSON, Richard, English Anglican prelate: b. Heversham, Westmoreland, August 1737; d. Calgarth Park, Westmoreland, 4 June 1816. He was graduated from Trinity College, Cambridge, in 1759, became professor of chemistry there in 1764 and in 1771 was appointed regius professor of divinity. He became archdeachon of Ely in 1780 and in 1782 was consecrated bishop of Llandaff. His writings include 'An Apology for Christianity' (1776); 'Chemical Essays' (5 vols., 1781–88); 'An Apology for the Bible' (1796), etc. Consult his son Richard, 'Anecdotes of the Life of Richard Watson' (1817).

WATSON, Richard, English Methodist clergyman: b. Barton-upon-Humber, Lincolnshire, 22 Feb. 1781; d. London, 8 Jan. 1833. He joined the Wesleyan Methodists at 15 and began preaching. He was ordained in 1800 and shortly afterward joined the Methodists of the New Connection, returning to the Wesleyans in 1812. He was appointed secretary of the Wesleyan Missionary Society in 1817 and in 1826 was president of the conference. He was for a time editor of the Liverpool *Courier* and wrote 'Apology for the People Called Methodists' (1800); 'Life of the Rev. John Wesley' (1831); 'A Biblical and Theological Dictionary' (1831); 'An Exposition of the Gospels of Matthew and Mark' (1833), etc. His collected works were edited by Thomas Jackson, in 13 vols., 1834–37, with 'Memoir.'

WATSON, Robert Spence, English publicist and lawyer: b. Gateshead, 8 June 1837; d. 1911. He was educated at University College, London, and established a law practice in Gateshead and Newcastle. He was president of the National Liberal Federation in 1890-1902 and has taken an active part in educational movements in Newcastle He is also known for his writings on economic subjects, particularly the labor question. His publications include 'Industrial Schools' (1867); 'Higher Education in Boroughs' (1868); 'The History of English Rule and Policy in South Africa' (1879); 'Irish Land Law Reform' (1881); 'The Relations of Labor to Higher Education' (1884); 'Boards of Conciliation and Arbitration and Sliding Scales' (1886); 'The Peaceable Settlement of Labor Disputes' (1889); 'Labor, Past, Present and Future' (1889); 'The Recent History of Industrial Progress' (1891); 'The Duties of Citizenship' (1895); 'Reform of the Land Laws' (1906), etc.

WATSON, Sereno, American botanist: b. East Windsor Hill, Conn., 1 Dec. 1826; d. Cambridge, Mass., 9 March 1892. He was graduated from Yale in 1847, studied medicine at the University of New York and in 1867–69 was botanist to the government exploration of the 40th parallel under Clarence King (q.v.). In 1871 he became assistant curator at the Gray Herbarium at Harvard and from 1874 until his death was curator there. He was elected Fellow of the National Academy of Sciences in 1889. Among his publications are 'Botany'; Vol. V of 'Reports on the Geological Exploration of the 40th Parallel' (1871); 'Bibliographical Index to North American Botany, Part I, Polypetalæ' (1878); with W. H. Brewster and Asa Gray, 'Botany of California' (2 vols., 1876–80), etc.

WATSON, Thomas, English poet: b. London, about 1557; d. 1592. While his fame may seem to have been eclipsed by that of Spenser and Sidney, among his contemporaries he was equally popular for his pastoral and love poetry. He lived in a learned age and translated the 'Antigone' of Sophocles into very elegant Latin. His 'Melibœus, Thomæ Watsoni; seu, Ecloga in Obitum Domini Francisci Walsinghami, Equitis Aurati' (1590) was a graceful Virgilian tribute to the memory of the statesman and diplomat Francis Walsingham (q.v.). His sonnets, 'Tears of Fancie; or Love Disdained,' evidently gave suggestions to Shakespeare in the composition of his 'Sonnets.' Consult Arber, 'English Reprints' (1892).

WATSON, Thomas Edward, American politican: b. Columbia County, Ga., 5 Sept. 1856; d. Washington, D. C., 26 Sept. 1922. He entered Mercer University but left before graduation and took up the study of law and was admitted to the bar in 1875. He began the practice of his profession at Thompson, Ga., and rapidly attained a reputation as one of the leading lawyers of the State. In politics he was at first a Democrat; was elected to the State legislature in 1882 and served as Democratic elector-at-large in 1888. He was active in the Farmers' Alliance movement and finally affiliated himself with the People's Party; in 1890 he was elected to Congress on the Populist ticket and for some time edited a Populist paper at Atlanta. While in Congress he obtained the first appropriation for the rural free delivery of mail. He was the Populist Party's candidate for Vice-President in 1896 and the Presidential candidate of the People's Party in 1904 and 1908. He was elected to the United States Senate as a Democrat in

1920 for the term 1921–1927. His publications include *Napoleon: A Sketch of His Life* (1902); *The Life and Times of Thomas Jefferson* (1903); and *Political and Economic Handbook* (1908).

Consult Woodward, C. V. *Tom Watson: Agrarian Rebel* (New York 1938).

WATSON, William, American scientist: b. Nantucket, Mass., Jan. 19, 1834; d. Sept. 30, 1915. After graduating from the Lawrence Scientific School of Harvard in 1857, he became an instructor there from 1857–1859; he then spent four years in Europe collecting information on technical education, which, when communicated to William Barton Rogers, first president of the Massachusetts Institute of Technology, played a part in the development of that institution. From 1865–1873 Watson was professor of mechanical engineering and descriptive geometry there. In 1884 he was elected secretary of the American Academy of Arts and Sciences. In addition to numerous articles he published *Papers on Technical Education* (1872); *A Course in Shades and Shadows* (1889); *Paris Universal Exposition: Civil Engineering, Public Works and Architecture* (1892); and *The International Water Transportation Congress, 1893* (1894).

WATSON, Sir William, English physician and scientist: b. London, England, April 3, 1715; d. there, May 10, 1787. As a botanist, a doctor, and an experimenter in electricity, Watson was in the first rank of the men of his time. He attended the Merchant Taylors School in 1726 and then served an apprenticeship to an apothecary, studying botany in particular, an interest which later led him to introduce the Linnaean system of classification into England.

In 1741 he was elected a fellow of the Royal Society, to which he contributed many papers on natural history, electricity, and medicine. He was licensed to practice medicine in 1759. In electricity his discoveries paralleled Benjamin Franklin's and in 1762 he advocated Franklin's lightning conductors for a British powder magazine.

He continued experimenting for many years after winning the Copley Medal in 1745, and it became the fashion in society to visit his home in London to observe his experiments. His medical work was chiefly concerned with epidemics, but he reported a cure for muscular rigidity by means of electricity, as well as observations on inoculation for smallpox.

WATSON, Sir William, English poet: b. Burley-in-Wharfedale, Yorkshire, Aug. 2, 1858; d. Ditchling Common, Sussex, Aug. 11, 1935. He began writing verse at the age of 14 and in 1880 published his first volume, *The Prince's Quest,* which showed the influence of Keats and William Morris and found favor with Rossetti. It was not until the publication of *Wordsworth's Grave and Other Poems* in 1890 that he gained recognition.

Odes and Other Poems (1894) contained *Vita Nuova,* one of his most admired poems, and in 1902 there appeared his *Ode on the Day of the Coronation of King Edward VII.* In 1928 he published *Selected Poems with Notes by the Author* and after his death there appeared *The Poems of Sir William Watson* (1930).

Watson was passed over for the laureateship when Alfred Austin died in 1913 and the honor went to Robert Bridges, but he was knighted in 1917. Watson's work was carefully wrought, conservative and romantic, and he belongs in the ranks of the minor British poets.

WATSONVILLE, wŏt's'n-vĭl, city, California, Santa Cruz County, is located at an altitude of 25 feet on both sides of the Pajaro River, about 5 miles from Monterey Bay and two miles south of the Big Basin State Redwood Park, on the Southern Pacific Railroad. It is in an agricultural and fruit growing region. Apples are one of the chief products and strawberries, lettuce, apricots, garden crops, and spray chemicals are also shipped from here. Industries include vegetable and packing houses, vinegar works, and evaporating plants. Watsonville was laid out in 1851, incorporated in 1868, and became a city in 1903. A mayor-aldermanic form of government was established in 1950. Pop. (1950) 11,572.

WATT, wŏt, **James,** Scottish engineer and inventor: b. Greenock, Renfrewshire, Scotland, Jan. 19, 1736; d. Heathfield, near Birmingham, England, Aug. 25, 1819. Having determined to adopt the trade of mathematical instrument maker, he spent a year in London learning the art, in which he attained great dexterity. After his return to Scotland, he endeavored to set himself up in business in Glasgow. In this he might not have succeeded—owing to the opposition of established men in the craft—had he not been appointed in 1757 mathematical instrument maker to the university, which lay outside of the jurisdiction of the Glasgow municipality. While thus employed he was also active in preparing surveys and reports in connection with canal, river, and harbor work.

It was during this period that he planned and completed most of his improvements of the steam engine. The idea of a separate condenser first occurred to him in 1764; in January 1769 he took out the patent for the improvements which incorporated this idea. Previous to Watt's time the cylinder itself had been used as a condenser and the jet of cold water introduced into the cylinder to condense the steam so reduced the temperature of the cylinder that three times as large a supply of steam (so Watt estimated) was demanded as was really needed. Watt set to work to condense the steam in a separate receptacle. The change was so important as to make him almost the inventor of the modern engine. But it was not until 1774 that he joined Matthew Boulton (q.v.), a manufacturer in Birmingham, in order to carry his improvements into execution. The two men originated the term *horsepower;* the *watt* and the *kilowatt* units of power, are named in Watt's honor.

Soon the Soho Engineering Works in Birmingham, where the steam engines were manufactured, had acquired a European fame.

Watt retired from the business in 1800, when his patent, renewed in 1775 for 25 years, expired. He was a fellow of the Royal Societies both of London and Edinburgh and one of the few Englishmen elected to the National Institute of France. Besides the separate condenser, Watt made other improvements in the steam engine. He devised the sun-and-planet gear wheel, made use of the expansion principle to obtain the double engine, applied a speed governor to steam engines, and invented the throttle valve. He built the first indicator for draw-

ing a diagram of steam pressure, patented a fuel-saving furnace, invented copying ink, and independently discovered the chemical composition of water. His memory was retentive and the range of his reading wide. Chemistry, architecture, music, law, metaphysics, and language were the principal subjects which, in addition to physical science and its practical application, engaged his attention, and in all of them his knowledge was wonderfully extensive, minute, and accurate. The significance of his work places him among the foremost of inventors. See also STEAM; STEAM-ENGINE.

WATT, SIR Robert Alexander Watson, Scottish physicist: b. Brechin, Scotland, April 13, 1892. Educated at Dundee University College, and was connected with the Meteorological Office of the Department of Scientific and Industrial Research from 1915 to 1936; he became superintendent of the Bawdsey Research Station of the Air Ministry (1936–1938). He has held various advisory posts and has been responsible for the development of British and American radar systems. He holds 14 patents for radio direction finders, of supreme value in World War II. He was knighted in 1942.

WATT, *in electricity,* the unit of activity or rate of doing work, named for James Watt (q.v.). See ELECTRIC MEASURING INSTRUMENTS; ELECTRICAL UNITS.

WATTEAU, wŏt'ō; Fr., vȧ-tō', **Jean Antoine,** French painter: b. Valenciennes, France, Oct. 10, 1684; d. Nogent-sur-Marne, July 18, 1721. His parents, whose situation in life was humble, with difficulty contrived to give him the instructions of a very inferior master in the country. In 1702 he went to Paris, in company with a scene painter, with whom he continued to work for a few months. Soon afterward he found employment with one Claude Gillot, who, although only a painter of decorations for ballet and a designer of costumes and of patterns for tapestry, was a true artist. With him he found an opportunity of practicing in all these branches of art and when he left him he found another master in Claude Audran, a very able man, keeper of the Luxembourg, who was of great service in opening to him the famous gallery of the palace in which Rubens had painted in allegory the history of Marie de Médicis. From the study of the great Flemish master he improved his coloring and when he left Audran in 1709 he was a consummate master of his art and a painter of *fêtes galantes.* He now began to paint on his own account, but met at first with little encouragement. He failed to secure the Prix de Rome, which would have enabled him to visit Italy, but soon afterward scored a triumph by his *Un Départ de Troupes.* He was admitted to the Académie in 1717 as a painter of *fêtes galantes* and produced many pictures whose power and grace in drawing and coloring his rivals strove in vain to emulate. His subjects were all genre, military, and civil. He excelled in reproducing the costumes, airs and graces of the fashionable world of his time. His *L'occupation selon l'Age* sold in 1891 for $27,300. The finest collection of Watteau paintings is in Berlin, others are to be seen in the Wallace collection, London, in the Louvre, Paris, and in the Leningrad, Vienna, Edinburgh and Glasgow galleries. See also PAINTING—*The 18th Century.*

WATTERSON, Henry, American journalist: b. Washington, D. C., Feb. 16, 1840; d. Jacksonville, Fla., Dec. 22, 1921. Privately educated, he began journalistic work as editorial writer for the Washington *Star.* In 1861 he joined the Confederate Army as a private and later was aide-de-camp to Gens. Nathan B. Forrest and Leonidas Polk. In 1862 he withdrew from the army to edit the *Rebel* at Chattanooga, a daily paper, recognized as an organ of the Confederate government, but, in 1864 he returned to the army and had part in Gen. Joseph E. Johnston's campaign, and the siege of Atlanta. At war's end he revived the publication of the Nashville *Republican Banner;* in 1867 he became editor of the Louisville *Journal.* This paper he united with the *Courier,* under the name of the *Courier-Journal,* of which he became editor in chief and which he made one of the leading Southern newspapers. He was active in politics as a member of the Democratic Party, although a leader in the Liberal Republican program of 1872; was delegate at large to every Democratic National Convention from 1872–1892, and was permanent chairman of that of 1876. He was a member of Congress in 1876–1878, and hotly opposed all greenback ideas. Though a staunch supporter of S. J. Tilden for the presidency, yet in Congress he was one of the leaders in obtaining a peaceable adjustment of the election dispute, and approved the appointment of the Electoral Commission, 1877 (q.v.). In 1896 he refused to support the Chicago platform of the Democratic Party, and was affiliated with the Gold Democrats. As a defender of the tariff, he was not over strenuous, believing that its main purpose was to raise revenue. He was ever antagonistic to trust policies and the dominance of industry by great capital. As speaker and editor he was a consistent advocate of free trade, and particularly of a policy of conciliation between the North and the South. He retained his vigor of utterance and influence in politics in his latter days. He published *Oddities of Southern Life and Character* (1882); *History of the Spanish-American War* (1899); and *Abraham Lincoln* (1899). In 1911 he was conspicuous as being among the first to urge the fitness of Woodrow Wilson for the presidency. His famous slogan "To hell with the Hapsburgs and Hohenzollerns" in 1917 was largely instrumental in arousing the United States to war against the German atrocities and brutal disregard of the rights of neutral nations. On March 2, 1919 a worldwide tribute was paid him in the special "Marse Henry edition" of the Louisville *Courier-Journal* in which over 200 thinkers and statesmen of the world voiced their esteem of the veteran editor.

WATTLEBIRD, wŏt"l-bûrd, or **WATTLE CROW,** an Australian honey eater (*Anthochaera carunculata*) so named from the large reddish wattles on its neck. It is about the size of a magpie, and is of bold, active habits. An allied species (*Dyottornis paradoxus*) inhabits Tasmania.

WATTLES, arborescent shrubs (*Acacia*) of Australia and Tasmania, in some places growing to good-sized trees. They have foliage which is compound or reduced to phyllodia, and pretty, crowded flowers, in globose or cylindrical heads. The wattles furnish a gum, used as an adhesive in cotton-printing; the stems make poles, which are serviceable for many

«bush» purposes. The bark is a valuable tanning material, known as mimosa- or wattle-bark, and many of the acacia forests have been killed by the stripping of their cortex for this purpose. A good quality of tan-bark is obtained from *A. decurrens* and *A. mollissima,* the black, green or feathered wattle found also in South Africa. It is one of the most graceful of the acacias and least destructive of this thorny race to person and clothing. The silver wattle (*A. dealbata*) is a taller tree than the black wattle, with ashen-tinted young foliage. The African wattle is *A. natalitia;* the Alpine, *A. pravissima,* from the Victorian Alps. *A. juniperina,* the prickly wattle, is an evergreen shrub of Australasia. The raspberry-jam wattle (*A. acuminata*) of the same region, yields a cabinet wood, having the odor of that sweetmeat. The wallaby- (*A. rigens*) and varnish-wattle (*A. verniciflua*), are also Australian shrubs. The soap-pod wattle is the same as the soap-nut of India. Savannah wattles are West Indian trees (*Citharexylum quadrangulare* and *C. cinerea*) of the verbena family.

WATTMETER. See ELECTRICAL TERMS.

WATTS, wŏts, **George Frederick,** English painter: b. London, 23 Feb. 1817; d. there, 1 July 1904. He studied in the Royal Academy and in 1837 exhibited there two portraits of young ladies and a subject-picture entitled 'The Wounded Heron,' and afterward contributed to various art exhibitions, notably the Royal Academy, the Grosvenor Gallery and the New Gallery, about 300 pictures of various kinds. Some of these are landscapes and seascapes; a few, such as 'The Sempstress' and 'Under the Arch,' portray contemporary life; but the finest and most characteristic are portraits and allegorical or ideal subjects. His portraits include those of the most eminent men and women of his age and perhaps form his chief claim to renown, as they were the basis of his reputation as an artist, and yet many of his idealistic pictures will continue to be copied after all the portraits are forgotten. Of his other pictures the following may be mentioned: 'Isabella Finding Lorenzo Dead' (1840); 'Paolo and Francesca' (1848); 'Life's Illusions' (1849); 'Sir Galahad' (1862); 'The Wife of Pygmalion' (1868); 'Daphne' (1870); 'The Curse of Cain' (1872); 'Dedicated to all the Churches' (1875); 'Love and Death' (1877); 'Time and Death' (1878), like the preceding one of his most notable pictures; 'Orpheus and Eurydice' (1879); 'Psyche' (1880); 'The Rider on the Pale Horse,' 'The Rider on the Black Horse,' 'The Rider on the White Horse' and 'The Rider on the Red Horse,' all apocalyptic pictures of 1883; 'Love and Life' (1884); 'Rain Passing Away' (1884); 'The Angel of Death' (1888); 'The Wife of Plutus' (1889); 'She Shall be Called Woman' (1892), a large picture of Eve; 'For He Had Great Possessions' (1894); 'The Outcast' (1895); 'Jonah' (1895); 'Love Triumphant' (1898); 'Court of Death' (1902). He was in Italy during 1843–47, and was powerfully influenced by Titian and Tintoretto. In 1847 his colossal oil-pictures of 'Echo' and 'Alfred inciting the Saxons to prevent the Landing of the Danes' were awarded a prize of £500 in another Westminster Hall competition. The latter of these now adorns a committee room of the Houses of Parliament. He completed a fresco, 'Saint George Overcomes the Dragon,' in 1853, for the Houses of Parliament and at a later date painted in fresco the west end of the new hall at Lincoln's Inn. After 1896 he was on the list of retired academicians. A large number of his portraits, presented by him to the nation, are now in the National Portrait Gallery, and some of his best allegorical paintings were presented to the National Gallery of British Art (Tate Gallery). To use his own words, he painted ideas rather than objects and the poetic idealism to which he was faithful throughout all his long career stood in the way of extensive popularity. His drawing was of the utmost correctness and his coloring often extremely fine, but while his allegorical subjects were often great in conception and treatment they sometimes required too much literary exposition to appeal to the ordinary picture lover in a clear and direct manner. His 'Life' has been written by his wife, Mary S. Watts, and appeared in London in 1912 in three volumes. Consult also Monkhouse, 'British Contemporary Artists' (1889); Bateman, 'G. F. Watts' (1901); Chesterton, 'G. F. Watts' (1904); Chesterton, G. K., 'G. F. Watts' (New York 1909).

WATTS, Isaac, English Congregational divine: b. Southampton, 17 July 1674; d. Stoke, Newington, London, 25 Nov. 1748. He was educated for the ministry at an academy in Stoke-Newington. In 1696–1702 he was a private tutor, in 1699–1702 was assistant to Isaac Chauncy, minister of the Congregational chapel in Mark Lane, London, and in 1702 succeeded to the pastorate. The congregation here was a distinguished one. Watts remained nominally pastor until his death, though from 1713 ill-health frequently interrupted his ministry, and Samuel Price was made co-pastor. Watts had in his own time great popularity as a writer, his manuals of religious instruction and his works of popular divinity having large circulation; while his 'Horæ Lyricæ' (1706) admitted him to Johnson's 'Lives of the Poets' and was reprinted in 1834 in a series of 'Sacred Classics' with a memoir by Southey, and his hymns, numbering in all about 600, were the chief part of the psalmody of English Nonconformist congregations. At the beginning of the 18th century only a few unimportant hymns had been written for Dissenters' use, the rule of Calvin having permitted only canticles and metrical Psalms. The dearth of suitable tunes and the custom of «lining out» hampered Watts' work; he had, too, many defects in rhyme and diction, was at times rhetorical and at others prosaic. But a number of his hymns are among the finest and most popular in English. Many are found in all hymn-books, and about a dozen remain in very general use. A collection was made in 1707, a second edition appearing in 1709. He published in 1722–24 doctrinal treatises of an Arian tendency, but grounds are wanting for believing that he finally passed to that position. His 'Works' were edited by Jennings and Doddridge in 1753; the 'Posthumous Works' were published in 1779. The former were reprinted with additions, and a memoir by Burder, in 1810. Consult Gibbons, 'Memoirs' (1780); Milner, 'Life' (1834);

Julian, J., *Dictionary of Hymnology,* 2d ed. (New York 1907); Benson, L. F., *The English Hymn: Its Development and Use in Worship* (New York 1915).

WATTS, Mary Stanbery (Mrs. Miles Taylor Watts), American author: b. Delaware County, Ohio, Nov. 4, 1868. She was educated at the Convent of the Sacred Heart, Cincinnati, and early engaged in literary work. She is well known as a writer of short magazine fiction and of novels dealing with American life. Author of *The Tenants* (1908); *Nathan Burke* (1910); *The Legacy* (1911); *Van Cleve* (1913); *The Rise of Jennie Cushing* (1915); *From Father to Son* (1919); *Luther Nichols* (1923).

WATTS, Thomas Hill, American politician: b. Butler County, Ala., Jan. 3, 1819; d. Montgomery, Ala., Sept. 16, 1892. He was graduated from the University of Virginia in 1840, established a law practice in Greenville, Ala., was elected to the state legislature in 1842, 1844–1845, and to the state senate in 1853. He opposed the secession movement, but upon the secession of Alabama accepted the situation. He was appointed colonel in the Confederate army and fought at Shilo, but resigned shortly afterward to become attorney general in the Confederate Cabinet. He was elected governor of Alabama in 1863, but was unseated by the federal government at the close of the war. He was thereafter engaged in law practice at Montgomery, and with the exception of 1880–1881, when he served in the legislature, held no further public office.

WATTS-DUNTON, Theodore, English poet, critic and novelist: b. Saint Ives, Huntingdonshire, Oct. 12, 1832; d. Putney, June 6, 1914. He was educated privately at Cambridge and for a time studied law, but had already gained a reputation as a writer of sonnets when he joined the staff of the *Examiner* as literary and art critic. Later he joined the *Athenaeum* staff, and for many years was one of the chief contributors to that review, his criticisms of poetry being of the most illuminating character. In 1897 he published a poem entitled *Jubilee Greeting at Spithead to the Men of Greater Britain,* which met with wide appreciation; and in the same year collected in *The Coming of Love, and Other Poems,* some of the more important of his poetical contributions. *Aylwin,* a novel or romance published in 1898 (privately printed in 1883), forms a striking prose counterpart to the *Coming of Love,* and contains excellent pictures of gypsy life.

Watts-Dunton also contributed largely to the *Nineteenth Century* and other periodicals. Several of the notices in Ward's *English Poets* are from his pen, and the valuable critical article on poetry in the *Encyclopaedia Britannica* was written by him. He and Swinburne (q.v.) were intimate friends. Later publications are *The Christmas Dream* (1901), and *The Renaissance of Wonder* (1902). On occasion Watts-Dunton makes free use of the Romany dialect, which he has carefully studied. His best work is probably the critical, especially that dealing with the principles of verse.

WATT'S DYKE. See Offa's Dyke.

WAUGH, wô, **Arthur,** English author: b. Midsomer Norton, Somerset, Aug. 24, 1866; d. London, June 26, 1943. He was graduated from Oxford in 1889, became a journalist in London in 1890, was London correspondent of the New York *Critic* in 1893–1897, in 1894 was sub-editor of the London *New Review;* in 1895–1902 was literary adviser to Kegan, Paul and Company, and was chairman and managing director of Chapman and Hall, Ltd. He wrote *Gordon in Africa* (1888); *Alfred, Lord Tennyson, a Study* (1892); *Legends of the Wheel* (1898); *Reticence in Literature* (1915); *Traditions in Literature* (1919); and edited Johnson's *Lives of the Poets* (6 vols., 1896); *Biographical Edition of Dickens* (1902–1903); *A Hundred Years of Publishing* (1930).

WAUGH, Evelyn Arthur St. John, English novelist: b. London, October 1903. The son of Arthur Waugh, he is best known for his ironical treatment of the ways of higher society in such novels as *Vile Bodies* (1930) and *Brideshead Revisited* (1945). He also wrote *Rossetti, His Life and Works* (1928) and an historical novel *Helena* (1950). His writings subsequent to 1930 show the influence of his conversion to Roman Catholicism.

WAUGH, Frederick Judd, American artist: b. Bordentown, N. J., Sept. 13, 1861; d. Provincetown, Mass., Sept. 10, 1940. He studied at Pennsylvania Academy, and in Paris, and worked abroad in 1892–1907. He exhibited at the Paris Salon and at the Royal Academy, London, and also worked as a newspaper illustrator in London. He gained a considerable reputation as a painter of marine subjects. His work is well represented in both public and private collections. He was elected to the National Academy of Design in 1911 and 1929 was awarded the Palmer Memorial Marine prize of $1,000. Among his works are *The Roaring Forties* (The Metropolitan Museum, New York); *Surf and Fog, Monhegan* (Art Institute, Chicago); *After a Northeaster* (National Gallery, Washington); *The Blue Gulf Stream* (Pennsylvania Academy). Author and illustrator of *The Clan of Munes* (1916).

WAUKEGAN, wâ-kē'gan, city, Illinois, Lake County seat, 40 miles north of Chicago, on Lake Michigan, and on the Chicago, North Western; Elgin, Joliet and Eastern (Belt Line); and Chicago, North Shore and Milwaukee (electric) railroads; and on federal and state highways. At an altitude of 669 feet, the city is on a bluff about 80 feet above the lake, and many ravines in the city are bridged for highways. There is a fine beach and a good harbor, giving Waukegan the advantages of lake traffic, especially in coal. It is an agricultural region, a summer resort, and a residential suburb, but has important manufactories. The chief products are: wire and wire products, asbestos roofing, chemical and pharmaceutical supplies, outboard motors, refrigerator units, enameled and finished iron castings, conveying and sealing machines, and leather. Great Lakes Naval Training Station is just south of Waukegan; and a little farther south is Fort Sheridan.

There was a French outpost here until about 1760. Pottawattomi Indians continued to live here long after this region became a part of the United States (1783). By Indian treaty white men were forbidden to settle here until after August 1836. The first white settler came in

1835 and the place was called Little Fort until 1849 when it was incorporated and took the Indian name Waukegan, which also means Little Fort. The Chicago North Western reached the town in 1855 and in 1859 it became a city. Government is by mayor and council. Pop. (1950) 38,946.

WAUKESHA, wô'kĕ-shô, city, Wisconsin, seat of Waukesha County, on the Fox River, 15 miles west of Milwaukee on the Chicago and North Western; Chicago, Milwaukee, St. Paul and Pacific; and Soo Line railroads; and at an altitude of 821 feet. It is an industrial city in a fertile agricultural area, where dairy farming is conducted extensively. Its industrial output is varied, including metal castings and articles of aluminum and iron; wire netting; window shades; leather goods; furniture, and gasoline engines. Quarrying is still another Waukesha industry, and bottled mineral waters, for medicinal and beverage use, are shipped out. From about 1870 to the 1900's, Waukesha might have been called the Saratoga of the West; it was widely favored as a watering place. The city has good schools and a public library, and is the seat of Carroll College (Presbyterian, coeducational), founded in 1841. The State Industrial School for Boys also is located here.

The Potawatomi Indians, who had a village here, ceded their land to the federal government in 1833. First white settlement was in 1834; it was known for some time as Prairieville. Its present name is Indian, meaning "little fox." Pop. (1950) 21,233.

WAUKON, city, Iowa, seat of Allamakee County, 85 miles northwest of Dubuque; on the Chicago, Milwaukee, St. Paul and Pacific Railroad. The region is agricultural, and Waukon's industries include flour mills, creameries, and stockyards. Here each year, in October, is held a celebration of Corn Day, with a program including a hog-calling contest. Unusually good trout fishing is found in the streams near by. Waukon, settled in 1851, has mayor and council. Pop. (1950) 3,158.

WAUPACA, wô-păk'ȧ, city, Wisconsin, seat of Waupaca County; 47 miles northwest of Oshkosh; on the Soo Line, and the Green Bay and Western Railroad. It is situated at an altitude of 868 feet in an agricultural and stock-raising region. The surrounding area was formerly engaged principally in lumbering, but Waupaca became one of the state's first centers for potato production and marketing, and still stands high in this activity. Within a few miles of the city there are more than a score of small, picturesque lakes, and the regional climate and scenery have brought Waupaca into favor as a summer resort. The streams and lakes afford excellent sport. Its name is an Indian word for "white sand bottom." Pop. (1950) 3,921.

WAUPUN, wô-pŭn', city, Wisconsin, in Dodge and Fond du Lac counties, 68 miles northwest of Milwaukee; on the Chicago, Milwaukee, St. Paul and Pacific Railroad. At an altitude of 888 feet, it lies in fertile farming country, in which there are creameries, condenseries, and canneries. The Wisconsin State Prison is located here, established in 1851. It has workshops in which goods are produced for use in state penal and charitable institutions. The city has two monuments: "End of the Trail," and "Angel of Peace," by James Earle Fraser and Lorado Taft, respectively. The municipality was founded in 1838. Pop. (1950) 6,725.

WAURIKA, wô-rē'kȧ, city, Oklahoma, seat of Jefferson County, 23 miles south of Duncan, on the Chicago, Rock Island and Pacific; Wichita Falls and Southern; and Wichita Valley railroads; in oil and cotton area. Pop. (1950) 2,327.

WAUSAU, wô'so, city, Wisconsin, seat of Marathon County, 140 miles north of Madison on the Wisconsin River; the Chicago, Milwaukee, St. Paul and Pacific, and Chicago and North Western railroads; and federal and state highways. It is at an altitude of 1,212 feet. Four miles to the southwest is Rib Mountain State Park with the highest point in the state (1,940 feet); the beautiful Dalles of the Eau Claire River are near by; and to the northwest is the lake region. The city lies on both sides of the river and the slope is gradual. The airport has land and water landings. At the western boundary of the city are the grounds of the Wisconsin Valley Fair and Exposition. Wausau is in a region of extensive lumbering, granite-quarrying and dairying interests, famous for its red clover and honey. There is abundant hydroelectric power. The chief manufactured products are lumber, veneers, sash and doors, boxes, toothpicks and other wood products; paper, electric motors and batteries, trailer and motor parts; shoes, animal feeds, malted milk and other dairy products; leather, chemicals, iron, steel, aluminum products, and dressed granite. A large employers' liability insurance company has its home office here. Besides good public and parochial schools and an adult and vocational training school the city has an extension division of the University of Wisconsin, offering years of college credits. There are 20 parks in the city.

The government is administered under a revised charter of 1892, which provides for a mayor and a council of 18 members elected for four-year terms. Many of the early settlers were German. The name is Indian for "far away." A dam and sawmill were built here about 1840. Wausau was platted in 1852 and existed under a town organization until 1861, when it was incorporated as a village. On March 18, 1872 it was chartered as a city. Pop. (1950) 30,414.

WAUSEON, wô'sē-ŏn; wô-sē-ŏn', village, Ohio, seat of Fulton County, 32 miles west of Toledo, on the Wabash; New York Central; and Detroit, Toledo and Ironton railroads. Its industries are food canning and miscellaneous manufactures. It has a public library, a public auditorium, and recreation centers. Settled in 1835, named for an Ottawa Indian chief, and incorporated in 1854, Wauseon has mayor and council. Pop. (1950) 3,494.

WAUTERS, wou'tĕrs, **Emile Charles Marie,** Belgian painter: b. Brussels, Nov. 29, 1846; d. Dec. 11, 1933. He was for four years the pupil of Portaels and of Gerome at Paris. His picture *Fair Edith finding the Body of Harold on the Field of Hastings,* attracted wide attention and he was sent by his government to attend in a professional capacity the opening of the Suez Canal. He returned from the East with many sketches and genre pictures and materials, out of

which he afterward painted his panorama, *Cairo and the Banks of the Nile.* His historical pictures are characterized by strong drawing and beauty of coloring. He did over 200 portraits of European contemporaries.

WAUWATOSA, wô-wà-tō'sà, city, Wisconsin, in Milwaukee County, five miles west of Milwaukee, on the Chicago, Milwaukee, St. Paul and Chicago Railroad, and the Soo Line. Its industries include lumber, cement, chemicals, and castings. It has a public library, city and county parks, and playgrounds. Settled in 1834, it became a city in 1897, and has mayor and council. Pop. (1950) 33,324.

WAVE MECHANICS. See QUANTUM THEORY—*Modern Developments.*

WAVELL, wā'vĕl, **Archibald Percival, 1ST EARL WAVELL,** British army officer and statesman: b. Colchester, England, May 5, 1883; d. London, May 24, 1950. From early childhood Viscount Wavell was destined for a military career, his father and grandfather having been army generals. Accordingly, he followed the conventional path, going first to Winchester School, then to the Royal Military College, Sandhurst. In 1901 the 18 year old lieutenant joined his father's regiment, the Black Watch, and was sent to South Africa where the Boer War was nearing its close. After a period at the Staff College from which he graduated in 1910 he spent two years on leave in Russia. There he became so proficient in the language that three decades later he was still able to carry on a conversation in Russian, and as a member of a mission to Moscow was the only British delegate able to speak with Premier Stalin in his own tongue.

At the outbreak of the First World War in 1914 Major Wavell went to France as a staff officer. Two years later he was wounded, losing the sight of one eye. After convalescence he joined the Russian Army in the Caucasus as British military attaché. Promoted brevet lieutenant colonel in 1917, he was attached to General Allenby's staff, Egyptian Expeditionary Force. Promoted brigadier general commanding Allenby's 20th Corps the following year, he relinquished that appointment in 1919 to become brigadier general of the general staff of the entire Egyptian Expeditionary Force.

After his Palestine campaigns, regimental duties on the Rhine, staff work in England and his military studies occupied him. In 1921 he was granted a full colonelcy in the regular peacetime establishment. His book, *The Palestine Campaigns* (1928), revealed a profound military intelligence coupled with a keen understanding of political factors rarely encountered among professional soldiers. Advanced to the rank of major general in 1933 at the age of fifty, he was the youngest officer of that rank in the British Army.

In 1935 General Wavell became commander of troops in Palestine and Transjordan. The following year he revisited Russia as the first British officer invited to attend the Red Army maneuvers. Returning again to the Middle East in 1937, he succeeded Sir John Dill in the Palestine command, but shortly afterwards relinquishing it, having been appointed commander in chief, Southern Command. A year later he was promoted lieutenant general. From 1939–1941 he was commander in chief of British forces in the Middle East; general (1940); commander in chief of British forces in India (July 1941); supreme commander of all allied forces in southwest Pacific (January 1942); of Allied forces in India and Burma (March 1942); field marshal (December 1942); viceroy of India (1943). In the latter year he was created Viscount Wavell of Cyrenaica and Winchester, and in 1947, shortly before India gained her freedom, was made an earl.

Wavell was the author of *The Palestine Campaigns* (1928); *Allenby, A Study in Greatness* (1940); *Generals and Generalship* (1941); *Allenby in Egypt* (1943); *Other Men's Flowers: An Anthology of Poetry* (1944); *Speaking Generally* (1946); and *The Good Soldier* (1947).

WAVELLITE, wā'vĕl-īt, an attractive, radiated mineral essentially a hydrous basic phosphate of aluminum, $4Al(PO_4)_2Al(OH)_3 + 9H_2O$. It rarely occurs in distinct orthorhombic crystals; usually it is in more or less complete spherical aggregates, externally showing crystal terminations and with radiated structure. Its hardness is 3.25 to 4, and its specific gravity about 2.32.

WAVERLEY, 'TIS SIXTY YEARS SINCE, a novel by Sir Walter Scott. It was the earliest of the world-famous series of romances to which it gives its title, and was published in 1814. The author withheld his name at first, from doubt as to the success of the venture. The continuance of the concealment with subsequent issues followed perhaps naturally; Scott himself could give no better reason afterward than that "such was his humor." Although the authorship of the series was generally credited to him, it was never formally acknowledged until the avowal was made in 1827 at a dinner for the benefit of the Edinburgh theatrical fund. *Waverley* is a tale of the rebellion of the Chevalier Prince Charles Edward, in Scotland in 1745.

WAVERLY, city, Iowa, Bremer County seat, 15 miles north-northwest of Waterloo on the Cedar River; the Chicago, Rock Island and Pacific, the Illinois Central, the Chicago Great Western the Waterloo, Cedar Falls and Northern railroads; and federal and state highways. It is in an agricultural, stock- and poultry-raising region and has a large number of butter, cheese, and condensed milk factories; corn canneries; a furniture factory; chemical works, and a considerable printing and publishing industry. The Wartburg College (Lutheran, coeducational) is here. Waverly Museum, belonging to the college, has exhibits from New Guinea of war clubs, spears, and grass skirts, as well as a valuable ornithological collection. The city is governed by mayor and council. Pop. (1950) 5,124.

WAVERLY, village, New York, in Tioga County, 15 miles east-southeast of Elmira on the Chemung River, and the Delaware, Lackawanna and Western, the Erie, and the Lehigh Valley railroads. The surrounding region is largely devoted to general farming and stock raising, and Waverly is a shipping point for large quantities of butter, cheese, milk, eggs, poultry, and vegetables and fruits. It has only small local industrial establishments. The village adjoins two municipalities across the line in Pennsylvania, Sayre and Athens; and many Waverly workers are employed in the Lehigh Valley Railroad's shops in Sayre. Waverly has a public library,

a town hall, and a high school. Pop. (1950) 6,037.

WAVERLY, village, Ohio, Pike County seat; altitude 570 feet; on the Scioto River; 20 miles by rail south of Chillicothe; on the Detroit, Toledo and Ironton, and the Norfolk and Western railroads. It is the trading center of a farming area, and has manufactures of lumber, wood products, and concrete products. The old Ohio and Erie Canal ran through Waverly. Founded in 1829, it displaced Piketon as county seat in 1861. Pop. (1950) 1,679.

WAVES OF ASSAULT. In modern warfare the intense effort demanded of assaulting troops, and the successive attacks which they must make, necessitate a deep formation. The several echelons thus constituted have been given the name of *waves*. But this term does not signify a uniform formation. The foremost waves, generally the first and the second, advance in line; those following are in various formations, for example, in lines of small columns. Moreover, to facilitate the leading of the echelons, the waves are formed by the simultaneous advance of tactical units not deployed in single line but themselves extended in the direction of depth, from which it results that a company or battalion will form a part of several successive waves. Formation for the assault does not consist of the deployment of rigid lines capable only of a movement straight to the front, but, on the contrary, of placing side by side tactical units which are capable of being led and even maneuvered.

WAVES AND WAVE MOTION. Energy may be transferred from one point to another or from one object to another by actual contact of the source of energy with the receiver. An example of this process is a locomotive moving a train of cars. Another very important method of transmitting energy is by means of waves. Modern communications depend largely on waves. Moreover, the great stream of energy from the Sun can be described in terms of wave motion.

Wave motion is characterized by the fact that a transport of matter does not take place. We have all seen waves on the surface of water, or waves running across a field of grain in a summer breeze. The second illustration clearly shows that the medium—in this case, the stalks of grain—is not transported but merely moves back and forth within a limited locality. We might be tempted to conclude that water is transported in wave motion when we see waves roll up on a shore. The motion does carry some water up on the shore, but, as the waves roll back, the net result is no transport of matter. The stalks of wheat at the edge of a field which bend over the fence and out of the field may be compared to the waves rolling up on the shore. In all wave motion it is the state of motion or disturbance that is handed on from one particle or region of a medium to the next. As a result, only the wave form travels onward.

Transverse and Longitudinal Waves.—Waves may be classified according to the motion of parts of the medium relative to the movement of the wave form itself. If the end of a long, horizontal stretched cord is made to vibrate up and down, a wave travels along its length. In this case, each segment of the cord moves transversely to the direction of travel of the wave form, and the result is a transverse wave. If one end of a long, spiral spring is suddenly compressed a short distance, the motion is transmitted to the adjacent coils. These in turn pass it on to the others, and a longitudinal or compressional wave passes along the spring. A sound wave in air is a longitudinal wave.

Waves on water surfaces, though easily observed, are some of the most complex we find in nature. If a small chip is placed on the surface of the water, it will be found to move in an elliptical or circular path as a wave passes its position. Both longitudinal and transverse motions are present in this case. Compressional waves can travel *through* water just as they can through air or any gaseous or liquid medium. A gas or liquid does not permanently resist a change of form which does not involve a change in volume and hence will transmit only compressional waves through its interior. Neither of these media will transmit a transverse wave.

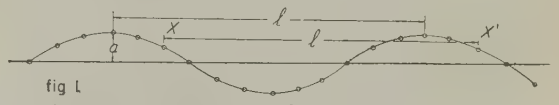

Fig. 1. Displacements in a transverse wave.

A flashlight photograph of a transverse wave traveling to the right is shown in Fig. 1. The particles normally on the straight line are displaced upward or downward. The maximum displacement (a) is called the amplitude of the wave. The distance (l) from crest to crest or from X to X^1, two points in the same phase, is called the wave length. In general, and certainly for sound waves, l is much greater than a. The number of waves per second that would pass a fixed observer is called the frequency of the wave. The wave length, frequency, and velocity are simply related as follows: Velocity = wave length $\times$ frequency. This formula is true for any type of wave.

In Fig. 2 is shown the displacement of particles in a medium through which a longitudinal or compressional wave is passing. In regions marked N, the particles have normal spacing or density, at C they are closer together, and at R they are farther apart. Regions C and R are called condensations and rarefactions, respectively. Fig. 1 can be used to represent a longitudinal wave if we allow distances above the horizontal line to represent forward displacements of the particle in the longitudinal wave, and distances below the line to represent backward displacements.

Fig. 2. Displacement of particles in a longitudinal wave.

Harmonic Waves.—The wave form shown in Fig. 1 is that which would be obtained by attaching a pen to the end of a vibrating tuning fork and moving it across a piece of paper. Such a wave is called a simple harmonic wave and is very common in nature. In his *La théorie analytique de la chaleur*, published in 1822, Baron Jean Baptiste Joseph Fourier (q.v.), French geometrician and physicist, proved that by properly combining simple harmonic waves any wave form encountered in nature can be represented accurately. A pure tone is produced when a sound wave can be represented by a simple harmonic

wave. The complex note of an organ or other instrument, or of the human voice, can be represented by a combination of simple harmonic waves. The wave with the lowest frequency is called the fundamental; the other waves that may be combined with it have frequencies which are integral multiples of the fundamental, and are often called overtones. It is the presence of different overtones that makes the quality of one voice or instrument differ from others. Fourier's discovery is not restricted in application to sound waves, but is also very useful in analyzing any wave or periodic phenomenon.

Wave Velocity.—The velocity of compressional waves through a medium depends on its density and elastic properties. An increase in density reduces the velocity; an increase in the forces required to produce a deformation increases the velocity. Within wide limits, the velocity is independent of amplitude and frequency of the wave. For extreme values of amplitude and frequency, however, the velocity is altered. For example, the sound wave from a large cannon travels somewhat faster near the gun that at some distance from it, where the amplitude is diminished. The velocity of sound in air also depends on the temperature. By measuring the velocity of earthquake waves through the earth, scientists are able to determine some of the characteristics of the interior of the earth.

The velocity of a transverse wave on a stretched, flexible cord depends on the tension of the cord and its weight per unit of length. The velocity of large waves on the surface of water depends upon several factors, including the depth of the water and the wave length of the wave. Tiny ripples have a velocity that depends on the surface tension of the water. Here again we note the complexity of waves on the surface of a liquid.

Interference; Light and Radio Waves.—A distinguishing characteristic of waves is that two trains of waves may combine so that at one point their effect (amplitude) is increased, and at another they may cancel one another or interfere. The fact that two light beams may be made to interfere and give zero intensity at certain points leads us to conclude that light can be represented as a wave motion. The interference pattern of two sets of waves can easily be seen on the surface of water. It was the demonstration of interference made by Thomas Young (q.v.), about 1800, that led to the acceptance of the undulatory or wave theory of light.

Radio waves are similar to light waves except that their wave lengths are much greater. The possibility of interfering with radio waves is well known. Light and radio waves differ from the other waves we have considered in that a material medium is not necessary for their propagation. Moreover, not all of the properties of light can be described in terms of waves. See also Acoustics; Harmonics; Interference; Light; Telegraphy and Telephony, Radio; Undulatory Theory of Light; Vibration.

Chairman, Department of Physics, University of Minnesota.

WAVEY. See Geese.

WAX, fatty solid animal substance, of which the typical sort is called beeswax. Various similar substances of vegetable and animal origin bear the name. Beeswax is secreted by bees in constructing their hives, and a very similar vegetable product enters into the composition of the pollen of flowers, covering the envelope of the plum and of other fruits, especially of the berry of the *Myrica cerifera,* and in many instances forming a kind of varnish to the surface of leaves. It is distinguished from fat and resinous bodies by its not readily forming soaps when treated with alkaline solutions. Common beeswax is always more or less colored, and has a distinct, peculiar odor, of both of which it may be deprived by exposure in thin slices to air, light and moisture, or more speedily by the action of chlorine. At ordinary temperatures wax is solid and somewhat brittle; but it may be easily cut with a knife, and the fresh surface presents a characteristic appearance, to which the name of waxy lustre is applied. Its specific gravity is 0.96. At 155°F. it enters into fusion, and boils at a high temperature. Heated to redness in a closed vessel it suffers decomposition, yielding products very similar to those which are procured under the same circumstances from oil. It is insoluble in water, and is only dissolved in small quantities by alcohol or ether.

In bleaching wax the wax must be melted, with a degree of heat not sufficient to alter its quality, in a caldron so disposed that the melted wax may flow gradually through a pipe at the bottom of the caldron into a large wooden cylinder that turns continually round its axis, and upon which the melted wax falls. As the surface of this cylinder is always moistened with water, the wax falling upon it does not adhere but quickly becomes solid and flat, and acquires the form of ribbons. The continual rotation of the cylinder carries off these ribbons as fast as they are formed, and distributes them through the tub. When all the wax ribbons to be whitened are thus formed, they are to be put upon large frames covered with linen cloth, which are supported about a foot and a half above the ground in a situation exposed to the air, the dew and the sun. If the weather be favorable, the color will be nearly discharged in a few days. It is then to be re-melted and formed into ribbons and exposed to the action of the air as before. These operations are to be repeated till the wax is rendered perfectly white, when it is cast into cakes or other commercial form.

The principal applications of wax are to make candles and medicinal cerates; to give a polish to furniture or floors, for which purpose it is largely used in the United States; to form a lute or cement, for which it is used by chemists; and to serve as a vehicle for colors. By modern painters colors previously prepared in oil are sometimes diluted just before being laid on in a mixture of wax and oil of turpentine. This practice is much resorted to by French artists, especially in mural paintings. The object is to keep the painting free from that lustrous appearance which often renders it difficult to be seen properly in consequence of reflection. Wax also forms a principal ingredient in modelers' wax and gilders' wax. In the former the other ingredients are druggists' lead-plaster, olive oil, yellow resin, and whiting; and in the latter verdigris and sulphate of copper. Sealing-wax is not properly a wax at all, but is composed of resin lac and some less brittle resin. The largest consump-

tion of wax takes place in Roman Catholic countries, where large quantities are required for the candles used in religious ceremonials.

Chinese wax comes from the ash tree on which it is secreted by an insect. It resembles spermaceti. Cork wax or cerin is extracted from cork by an alcoholic process. Mineral wax or ozocerite is a waxy paraffin. Shoemaker's wax is a mixture of pitch and tallow. Wool wax is the solid greasy product obtained from sheep washing, is used as a dressing for leather, and is an adulterant or base for ointments. See also WAX, VEGETABLE.

Wax Figures.—The employment of wax in imitative art dates from a period anterior to historical times, although, according to Pliny, the art of casting it in molds was not practiced previous to the time of Lysistratus, its reputed inventor, who flourished about 300 B.C., and whose productions were chiefly portraits cast in plaster molds taken from the face. Wax portraits eventually became common. Among the Romans, who placed them in the vestibules of their houses, they were regarded as an evidence of ancient nobility, as none were allowed to possess such images whose families had not borne some curule magistracy.

In the Middle Ages, wax was employed in the construction of images of saints and of votive images, and those who practiced sorcery melted before a slow fire wax figures of the persons against whom their incantations were directed.

In the latter half of the 15th century Andrea del Verrocchio and Orsino Benentendi gained considerable reputation by some figures of Lorenzo de' Medici, their joint production, which consisted of frameworks of wood or skeletons for the bodies and limbs, while the heads, hands, and feet were cast in wax and painted in oil colors to counterfeit life. They were furnished with glass eyes and natural hair, and were habited in the costume usually worn by Lorenzo.

The manufacture of life-sized wax figures is still carried on to a considerable extent, but has long ceased to be considered a branch of the fine arts. In the preparation of anatomical models and pathological examples, however, wax has been very advantageously employed, the invention being due to Gaetano Giulio Zumbo, a famous modeler in colored wax, who flourished in the latter half of the 17th century. In the succeeding century the celebrated collection of anatomical models in the Institute of Bologna was begun under the direction of Ercole Lelli. In the Museum of Natural History at Florence are several chambers devoted to preparations by Felice Fontana, Antonio Susini, and other celebrated modelers; the Musée Dupuytren at Paris is famous for its morbid specimens; and almost every city of Europe now has its collection.

The collection of wax figures at the Eden Musée in New York was for about 50 years prior to 1910 one of the show features of the city. In London, Madame Tussaud's Museum is world famous. See TUSSAUD, MARIE GRESHOLTZ.

WAX, Mineral. See HATCHETTINE.

WAX, Vegetable, a solid, fatty substance, resembling animal wax, which is secreted by many plants, sometimes in large enough quantities to be of commercial importance. On foliage, it forms a varnish or coating, which prevents excessive transpiration or wetting of the cells; and on twigs and flower pedicels, by its slippery surface it keeps unwelcome insects from reaching the flowers and robbing them of their honey. The whitened undersurfaces of some willow leaves and the bloom of fruit are composed of wax either in granules or rods, or spread over the cuticle.

The most familiar example in America of the hard fat or wax in quantity is on the bony nutlets of the wax myrtles or bayberries (*Myrica*). The gray-coated drupes of *M. carolinensis* clustering on the bare twigs are conspicuous in seashore regions, after the leaves are fallen; the wax clinging to their rough, granular surfaces when melted is a greenish, hard substance, sharing the balsamic odor of the plant. It was used in colonial times as a basis for candles and for soap. Other species furnish a similar wax and are known as candleberries or tallow trees. (See WAX MYRTLE.)

Carnauba wax is exported from Brazil for candles and as a substitute for beeswax. It is the coating on the young leaves of the wax palm, *Corypha cerifera,* indigenous to tropical South America. The young leaves are removed and dried; the wax granules may then be shaken off in the form of a fine dust, melted, and caked. Japan wax is a waxlike, hard fat, which is largely exported from Japan to Europe, in yellowish, hard cakes with a resinous, rancid odor, and often covered with a powdery efflorescence. See also SUMAC OR SUMACH.

WAX MYRTLE, mûr't'l, an evergreen shrub or tree with aromatic leaves, unisexual flowers borne in catkins, and often with waxy fruits, belonging to the genus *Myrica,* family Myricaceae. Fifty species occur in moist habitats in the Northern Hemisphere. Some are cultivated as ornamentals. The name candleberry is applied to two species of the eastern United States: *M. cerifera,* a small tree up to 30 feet tall with a waxy coating on the fruits, leaves, and young stems which grows in woods and swamps of the southeastern states; and *M. pennsylvanica,* a shrub with less waxy herbage, found on the northeastern coastal plain. The bluish white wax, when mixed with tallow, serves for the making of fragrantly burning candles. The name sweet gale refers to a common species of the British moors, *M. gale.* The California bayberry, *M. californica,* is a small tree in the redwood forest of the Pacific coast.

WAXAHACHIE, wôk-sȧ-hăch'ē, city, Texas, seat of Ellis County; altitude 585 feet; 42 miles southeast of Fort Worth. It is served by the Chicago, Rock Island and Pacific, the Fort Worth and Denver, the Missouri-Kansas-Texas of Texas, and the Southern Pacific railroads, and has an airport. It is an important cotton center and has cottonseed oil mills, a cotton compress, and a textile mill manufacturing duck and similar heavy goods. The city has a standard school system and a public library. It is the seat of the Southwestern Bible Institute, founded in 1927. Trinity University, formerly located here, was removed to San Antonio in 1942. Waxahachie was founded in 1847 and incorporated in 1871. Pop. (1950) 11,204.

WAXBILL, an African weaverbird (q.v.), one of the section of the family called blood finches on account of the prevalence of red in the plumage. This has long been a favorite among cage birds and is sold by dealers all over the world. It is nearly five inches long. The

beak is bright red and somewhat swollen. A bright red stripe passes between the eyes and the middle of the breast, and the belly is a beautiful reddish brown. The upper surface of the body is brownish gray, the lower surfaces lighter, everywhere traversed by very fine blackish wavy lines; wings and tail are brown. Waxbills are varied in color by breeders, who have developed some with bright blue tints. Their song is not very musical, but they are pretty and affectionate to a high degree. Their food and care should be similar to those given a canary. Some of the birds look like miniature pheasants.

WAXFLOWER or **MADAGASCAR JASMINE.** See STEPHANOTIS.

WAXWING, a woodland bird of the genus *Bombycilla* (also known as *Ampelidis*), a small isolated group of birds of the Northern Hemisphere, characterized by their shrikelike beaks, silky brown plumage, tall erectile crests, and especially by the tips of the wing and tail quills terminating in flattened scales closely resembling red sealing wax. The northern or Bohemian waxwing (*B. garrula pallidiceps*) makes its home near the Arctic coasts of both continents and breeds there in trees, long before the snow has disappeared in the spring. Sometimes it is not seen in the United States or central Europe for years but will appear locally in large numbers. These erratic movements, doubtless due to presence or absence of food which consists of both insects and berries, were regarded by the superstitious peasants as a sign of pestilence or war. See also CEDAR WAXWING.

WAXWORKS, collections of wax figures, usually representations of real persons. See TUSSAUD, MARIE GRESHOLTZ; WAX—*Wax Figures.*

WAY, Right of. See RIGHT OF WAY.

WAY OF ALL FLESH, The, a novel by Samuel Butler (q.v.), published posthumously in 1903. A severely critical study of Victorian life in general and domestic life in particular, it traces the history of four generations of the Pontifex family from that of John Pontifex, a rural carpenter of considerable amateur attainments in the arts, to that of his great grandson, Ernest, who emerges as the hero of the tale and who is searchingly tested by circumstance before he is allowed to find his way to a secure plateau of worldly wisdom, literary accomplishment, inherited wealth, and permanent bachelorhood in London. Butler's well-known iconoclasm is directed with particular relentlessness upon Ernest's father, Theobald, a Church of England clergyman, who rears his son from infancy with equal parts of stupidity and impatience, plus liberal doses of cruelty and bullying, all the while convinced that he never departs from the loftiest possible conception of Christian duty. Lesser persons of thematic importance include Ernest's mother, a woman of limited intelligence but unlimited powers of self-dramatization; the pretty, dipsomaniac Ellen, onetime servant in Theobald's household with whom Ernest forms a temporary union after his release from prison; and Ernest's godfather, Overton. It is Overton who ostensibly tells the whole story from the point of view of an interested family friend. As spokesman for the author, he may be considered a self-portrait of Samuel Butler in later life.

Subsequent generations of readers are prone to find *The Way of All Flesh* somewhat too didactic and even at times improbable, more especially at moments when the lives of its characters are manipulated to illustrate one or another of the novelist's preconceptions concerning the role of heredity and environment in human affairs. At the same time, however, the book has been judged by time to contain its full share of gifted and compelling story, the illusion of life being very nearly absolute for long and brilliantly sustained passages. There is likewise the consideration that it has proved to be a rich mine of material for later writers with similar interests, however little the source may be recognized or admitted. Among those who have openly acknowledged their indebtedness is George Bernard Shaw, who writes of Butler's autobiographical masterpiece as follows in the preface to *Major Barbara:* "It drives one almost to despair of English literature when one sees so extraordinary a study of English life . . . making so little impression that when, some years later, I produce plays in which Butler's extraordinarily fresh, free and future-piercing suggestions have an obvious share, I am met with nothing but vague cacklings about Ibsen and Nietzsche. . . . Really, the English do not deserve to have great men."

MARKHAM HARRIS,
Department of English, University of Washington.

WAY OF THE WORLD, The, a play by William Congreve (q.v.). The author was already the leading playwright and one of the most elegant gentlemen of London when in 1700, in his 30th year, he brought out at Lincoln's Inn Fields *The Way of the World* with his friend Mrs. Ann Bracegirdle in the principal role of Millamant. The play was written with a conscious aspiration "to write only to the few refined." It was the author's purpose "to design some characters which should appear ridiculous, not so much through a natural folly (which is incorrigible and therefore not proper to the stage) as through an affected wit, a wit which at the same time that it is affected is also false." The venture was not entirely a success and Congreve's career as a playwright was at an end.

It may profit us to inquire why the play failed and why in spite of its failure it is hailed as one of the greatest of the world's comedies. By the time of Congreve there had been added to the overemphasis and grotesqueness of Ben Jonson's comedy the refining touch of Molière. Comedy now becomes an art of manners, a pattern of human ingenuity at its wittiest and best. It was Congreve's distinction that he best adapted the technique of town living to the technique of the stage. Interested in character he is even more interested in social groups:

> poets oft in one piece expose
> whole belles—assemblees of coquettes and beaux.

The play is rendered caviar to the general by its superabundance of dazzle, a radiance that conceals, as by principle, the real humanity of some at least of the characters. Moreover, the characters quite run away with the author in their good spirits and lavish life, leaving his plot unclear and a matter of raveled ends and hasty explanations. But these things cannot be counted faults by one who loves

Congreve. He only among English writers has raised the artifices of character to universality. In language, observation, wit he presents a fine texture of grace that provokes and satisfies thoughtful laughter. Millamant is one of the rarest creations in literature, the woman entrancing as distinguished from the woman emotional or the woman instinctive. Though he is dealing with a conventionalized society Congreve's characters are thoroughly individualized in their several relationships with that society. As is natural for such a society, most of the characters are women, but the characters that stand out, with one exception, are men. Written after Jeremy Collier's blast against the immorality of the stage, the play shows some of the restraining influence of this divine's charges. It was often presented during the 18th century, but has been the particular delight of the study. Editions: Ewald, A. C., ed., Mermaid Series, 1887; Street, G. S., *Comedies of William Congreve,* 1895.

THOMAS H. DICKINSON.

WAYCROSS, wā'krŏss, city, Georgia, Ware County seat; altitude 138 feet; 96 miles southwest of Savannah, and 58 miles west of Brunswick; on the Atlanta, Birmingham and Coast; and the Atlantic Coast Line railroads. In this area are forests of pine, cypress and gum, creating several local industries. The city is a commercial center for lumber, naval stores and cotton. It has manufactures of lumber, caskets, veneer, footwear, beverages, apiaries, and a hatching and a refrigerating plant; and, until 1937, was important for the marketing of furs and alligator hides. Before state-wide prohibition went into effect in Georgia, Waycross secured virtual prohibition by the imposition in 1883 of a license fee of $20,000 upon dealers in intoxicating liquors and by increasing this fee to $30,000 in 1892. The educational institutions include a high school for whites, established in 1890, a high school for Negroes, and public and private schools. Waycross was settled in 1870, incorporated in 1874 and became a city in 1909. The waterworks are municipally owned. Pop. (1940) 16,763; (1950) 18,899.

WAYLAND, wā'land, **Francis,** American college president: b. New York, March 11, 1796; d. Providence, R. I., Sept. 30, 1865. He was graduated from Union College in 1813, studied in the Andover Theological Seminary, was a tutor at Union College 1817–1821; in 1821 became pastor of the First Baptist Church of Boston and took a leading place in the ranks of American preachers, his sermon on *The Moral Dignity of the Missionary Enterprise* (1823) being particularly well known. After holding a professorship at Union (1826–1827), he became president of Brown University. During the 28 years of his administration he greatly developed the institution and was one of the pioneers of the elective system in American universities. Subsequent to his resignation (1855) he was for a year and a half pastor of the First Baptist Church of Providence, after which he devoted himself to various kinds of religious and humanitarian effort. He was the author of many valuable works, including *Elements of Moral Science* (1835); *Elements of Political Economy* (1837); *The Limitations of Human Responsibility* (1838); *Domestic Slavery Considered as a Scriptural Institution* (1845); *The Elements of Intellectual Philosophy* (1854); and *Sermons to the Churches* (1858). Consult Murray, S. O., *Francis Wayland* (Boston 1891); Wayland, F. and H. L., (his sons), *A Memoir of the Life and Labors of Francis Wayland* (New York 1867).

WAYLAND, **Francis,** American legal scholar, son of the preceding: b. Boston, Mass., Aug. 23, 1826; d. New Haven, Conn., Jan. 9, 1904. He was graduated from Brown University in 1846, took his M.A. degree from Yale in 1872, and began law practice in Worcester, Mass., in 1850, removing in 1858 to New Haven. He was judge of probate in 1864–1865, and lieutenant-governor of Connecticut in 1869. In 1872 he became professor in the law school of Yale, and in 1873 dean of the school. In 1903 he resigned the deanship. The development of the school from a minor local institution to its present condition, with adequate financial basis and wide curriculum, is due chiefly to him. He was president of several organizations, including the American Social Science Association, the board of directors of the Connecticut State Prison, the Prison Aid Association from 1872, and the Organized Charities Association of New Haven from 1878. He was prominent as a writer and speaker on sociological and charitable topics and criminology, and was joint author, with his brother, H. L. Wayland, of the memoirs of President Wayland (1867).

WAYLAND THE SMITH (AS. *Weland;* ON. *Völundr;* Icel. *Voelund;* OHG. *Wiolant, Wielant;* Ger. *Wieland;* Fr. *Galans, Galant, Galland;* Lat. *Guielandus*), a smith of Teutonic legends.

According to the elder Edda (q.v.), Voelund and his two brothers, Slagfid and Egill, settled in the Valley of Ulfdal, and lived with the Valkyries. After seven years, two brothers left in search of their wives, but Voelund remained at home accumulating wealth. He then went in to the service of King Nidung who cruelly lamed him by cutting the sinews of his legs, and transported him to an island where he was forced to work. As revenge, Voelund murdered the king's two sons, mounted their skulls in silver cups and presented them to the king, set the eyeballs in precious metal and gave them to the queen, and lastly, turned their teeth into pearls which he gave to the king's daughter, Baudvilde, whom he later violated. Voelund then put on a feathered robe and flew away. In various other versions, the smith was apprenticed to Mimer (Mimir) and wrought Mimung along with other famous swords to which there are many literary allusions.

A striking analogy may be seen in the story of Daedalus (q.v.) who entered the service of Minos, as Weland did of Nidung; Minos had a daughter, like the Scandinavian king; and Daedalus, like the Scandinavian hero, incurred the vengeance of the king he served. Each in turn violated the king's daughter, and escaped by making wings and flying. Other comparisons show similarity to Vulcan, the Roman god of fire, and Hephaestus (q.v.), the Greek god of metalworking. The Scandinavian sources for the story are *Voelundr Quida,* an early ballad in the Edda,

and *Wilkina Saga*, which is probably of German origin.

In Anglo-Saxon literature, there is a poem fragment which retraces the story and tells the grief of Beadohilde; in *Beowulf*, a hero leaves his best suit of armor, which was the work of Weland, to his companion, Higelac; *Deor's Lament* retells the story; King Alfred, in translating the *Consolations of Philosophy* by Boethius, writes: "Where are now the bones of the wise Weland, the goldsmith who was formerly most famous?"; in the Arthurian tale of Geoffrey of Monmouth, Rhydderic gives to Merlin precious stones and vases which were the work of Weland; in *King Horn*, Rimenhild gives a sword named "Bitterfer" to Child Horn; Chaucer, in the *Merchant's Tale*, refers to Wade, the sea giant father of Weland, and in *Troilus and Cressida* (book 3, line 614), makes another allusion. The legend that in a vale in Berkshire at the foot of White Horse Hill, a traveler might tie his horse, leave money for the fee, retire, and upon returning, would find his horse shod, was used by Sir Walter Scott in *Kenilworth*. The earliest known record of Weland is on a fragment of an 8th century Northumbrian styled casket.

WAYNE, Anthony, American Revolutionary officer: b. Waynesborough, Chester County, Pa., Jan. 1, 1745; d. Presqu' Isle (now Erie), Pa., Dec. 15, 1796. He was the son of Isaac and Elizabeth Iddings Wayne, and grandson of Capt. Anthony Wayne, who had emigrated from Ireland and in 1724 acquired a tannery and some 500 acres of land near Paoli, Pa., naming the estate Waynesborough.

Young Anthony attended his uncle Gilbert Wayne's local school, and in 1759 his father sent him to the Philadelphia Academy (now the University of Pennsylvania).

In 1765 Wayne was sent by a Philadelphia land company to survey a wild tract of about 100,000 acres in Nova Scotia and supervise its settlement. He returned to Philadelphia to marry Mary Penrose, daughter of a wealthy merchant, on March 25, 1766, and the couple immediately sailed for Nova Scotia. Wayne, however, was able to persuade only about 50 European immigrants to take up homes there; the soil would not grow sufficient grain to feed the settlers, and the threat of starvation ended the venture early in 1767. Back at Waynesborough, Anthony helped his father run the farm and tannery, a profitable business to which he succeeded upon the elder Wayne's death in 1774.

As anti-British feeling mounted in the colonies, Wayne became active in politics, was elected to the Pennsylvania Assembly in 1774, and organized a regiment in Chester County in 1775. On Jan. 3, 1776, he was commissioned colonel of the 4th Pennsylvania Battalion ordered to assist Benedict Arnold in his retreat from Quebec.

Wayne reached Albany, N. Y., by sloop and then marched his troops to Lake George, where small boats carried them up Lake Champlain and the Sorel River in Canada to the St. Lawrence River. On June 10, 1776, there was a sharp battle at Three Rivers, near Quebec, where Wayne unexpectedly met an overwhelming force of British. He withdrew to Fort Ticonderoga, N. Y., and remained there for almost a year as commander, with a force of 2,500 men. He was promoted to the rank of brigadier general on Feb. 21, 1777, but this did little to offset his disgust with the wretched conditions and inactivity at the fort.

On April 12 Wayne joined Washington at Morristown, N. J., and took command of eight regiments known as the "Pennsylvania Line," composed of descendants of Scotch-Irish and German settlers. He instilled magnificent *esprit de corps* into this group, which he was to lead through many trying months. On July 24, 1777, he was sent to Chester, Pa., to train militia recruits, and after a short visit at Waynesborough returned to the army, then camped north of Philadelphia.

The American cause was now approaching its gravest crisis, as Sir William Howe with a formidable force advanced on the capital at Philadelphia. Wayne took a prominent part in the fighting around the city. On Sept. 11 his division held back 7,000 Hessians at Brandywine Creek (Chad's Ford), Pa., while the rest of Washington's army escaped Howe's flanking movement and retreated. At Paoli, late in the evening of Sept. 20, while obeying orders to harass the enemy, Wayne was driven back by a bayonet charge under Gen. Charles ("No Flint") Grey, who had superior numbers. Accused of negligence in this defeat, Wayne demanded a court martial, which acquitted him "with the highest Honor." At the Battle of Germantown, Oct. 4, his command pushed the British almost three miles south, but he was later forced to retreat because of confusion in a heavy fog.

Philadelphia had been lost, and the American Army withdrew to Valley Forge. There, during the terrible winter of 1777–1778, Wayne shared the sufferings of his men, although his comfortable estate was only five miles south. After a month's furlough due to ill health he successfully raided New Jersey for cattle desperately needed at the Valley Forge encampment.

In the latter part of June, 1778, Sir Henry Clinton began the evacuation of Philadelphia and headed for New York. On June 28, at Monmouth, N. J., Washington attacked his long baggage train. The crack British guards, flower of the army, retaliated with a bayonet charge against Wayne's forces which had been ordered by Washington to harass the enemy's center. The guards were repulsed with great loss, but the American Army was incapable of resuming the offensive and during the night the British continued their march north.

During an indefinite leave of absence beginning Feb. 1, 1779, Wayne lobbied in the Pennsylvania Assembly for more effective aid for his ragged soldiers. On June 24 he received Washington's letter to join him below West Point, N. Y., and take command of the new light infantry, composed of picked troops from several states. At midnight July 15, 1779, Wayne stormed Stony Point, N. Y., an almost impregnable fort standing out on a high rock near the west bank of the Hudson River, threatening the security of West Point. Three columns waded waist-deep over a flooded marsh to the attack, the center firing noisily while the other two flanked the fort with bayonets on empty muskets. Personally leading one of the columns, Wayne subdued the garrison in the most brilliant action of his career, one of the great exploits of the Revolutionary War. His astonishing victory—followed by clemency for the defeated, so that only 63 British soldiers were killed—sparked the morale of troops and civilians throughout the country. Messages of congratulation and rejoicing flooded Congress. The marquis de Lafayette warmly congratulated Wayne. The following day Washington rode down to express his thanks, and on July 20 sent a message to Congress declaring that Brigadier General Wayne's "own conduct throughout the whole of

this arduous enterprise merits the warmest approbation of Congress. He improved upon the plan recommended by me, and executed it in a manner that does signal honor to his judgment and to his bravery. In a critical moment of the assault, he received a flesh-wound in head with a musket-ball, but continued leading on his men with unshaken firmness." Congress presented a medal to Wayne in recognition of his gallant achievement. His victory was a great blow to British prestige.

It was such headlong daring, often bordering on recklessness, which won for Wayne the appellation "Mad Anthony." Always in the heat of every action, he chose the post of greatest danger, exhibiting a boldness that gained him the universal affection of his troops.

The light infantry was dissolved on Jan. 1, 1780, and Wayne returned to Philadelphia to plead once more for the army, then at Morristown. On the evening of Sept. 26, 1780, while camped at Haverstraw, N. Y., Wayne received word from Washington of Benedict Arnold's treason at West Point. Wayne marched his Pennsylvania regiments 16 miles in four hours to protect the fortress, his prompt movement forestalling a possible British attack.

The Pennsylvania Line, payless for nearly a year, lacking food and clothing, and with many serving beyond their period of enlistment, mutinied at Morristown on the night of Jan. 1, 1781. Wayne, chosen as their intermediary to the State Assembly, won most of their demands. Yet, when ordered to join Gen. Nathanael Greene and Lafayette in the South, Wayne could muster only 800 men. Before they were ready to leave York, Pa., a court martial condemned three mutineers to death when another revolt seemed imminent.

At Green Springs, Va., July 6, 1781, false information lured Wayne into a trap with a swamp behind him and Gen. Charles Cornwallis' entire army of 4,000 men waiting in ambush before him. Wayne called for a daring advance, leading the British to believe American reinforcements had arrived. Before Cornwallis could recover, Wayne's 500 troops had steadily retreated over a narrow causeway. One of Lafayette's sentries accidentally shot Wayne in the thigh on Sept. 2, an injury which limited his activity at the siege of Yorktown, Va., where Cornwallis surrendered on Oct. 19, 1781.

British resistance continued in the South, and in February 1782 Wayne was sent by Washington to serve under Greene in Georgia. He camped at Ebenezer, near Savannah, with 600 men, while Gen. Alured Clarke held the port with 1,800 British regulars. Wayne made a remarkable four-mile march over a causeway and crossed a vast swamp on the night of May 24 to assault 450 redcoats under Col. Thomas Brown, completely unnerving them and forcing them back to Savannah. On June 24 he roused his sleeping men in time to rout 300 Creek Indians—British allies—killing their leader, Chief Guristersijo (Emistisiguo), with a sword thrust. No longer able to hold Savannah, the British evacuated the city on July 11. In September Wayne had a violent attack of fever from which he never completely recovered, and late in July 1783 at last sailed for home. He had liberated Georgia with an incredibly small force, and that state rewarded him with an 847-acre rice plantation located 12 miles northwest of Savannah.

Wayne arrived in Philadelphia in shattered health, but the care of his close friend and physician, Sharp Delany, and the companionship of old friends proved a good tonic. Upon his retirement in October 1783 Congress belatedly appointed him brevet major general, and he became a member of the Pennsylvania Council of Censors, a body which tested the validity of Assembly acts. He spent his evenings lavishly entertaining the most famous people of the day, forgetful that such indulgence aggravated his frequent attacks of gout. As representative of Chester County in the Pennsylvania Assembly in 1784 and 1785 he worked for fair treatment of loyalist refugees and for the licensing of his favorite art, the theater, which was still forbidden in Quaker Philadelphia.

Late in 1785 Wayne went to live on his Georgia plantation, which he eventually lost to creditors after a bitter financial struggle. After he had served for a year (1791–1792) as congressman from Georgia, his seat was declared vacant following evidence of fraud in his election and irregularity in his residence qualification.

Meanwhile, ignoring the peace treaty of 1783, the British had still been holding forts in the Northwest Territory and inciting various Indian tribes to attack American settlers; and in November 1791 Gen. Arthur St. Clair had suffered a crushing defeat by the Indians. To cope with the situation, President Washington recalled Wayne and in April 1792 named him major general in command of the army in the West. Wayne enlarged the army and began training his raw recruits. In the midst of this program (April 1793), he learned of his wife's death at Waynesborough.

On April 30 Wayne began a march of over 400 miles into enemy territory. Profiting by St. Clair's mistakes, he maintained constant vigilance, set out excellent scouts, and built three strong forts on the way. On Aug. 20, 1794, he met about 2,000 Indians at Fallen Timbers (near present Toledo), Ohio, and with only a third of his 3,000 men taking part, drove the Indians in 40 minutes to British-held Fort Miamis, and thoroughly cowed them. Washington appointed Wayne sole commissioner to negotiate peace with the Indians. While awaiting their reply he built Fort Wayne, Indiana, to command the waterways to Lake Erie. On Aug. 3, 1795, the Indians finally signed a treaty at Fort Greeneville, Ohio, which brought peace for 15 years.

After a brief and triumphant return to Philadelphia on Feb. 6, 1796, Wayne was sent west again to take possession of the British forts abandoned under Jay's Treaty of 1795. He sailed from Detroit, Mich., to the Presqu' Isle, Pa., blockhouse on Nov. 17, 1796, and died there Dec. 15. He left two children, Margaretta and Isaac, who subsequently brought their father's remains to the family plot in the graveyard of St. David's Church in Radnor, Pa., July 4, 1809.

Bibliography.—Most important source is the collection of Wayne manuscripts and letters at the Historical Society of Pennsylvania, Philadelphia, Pa. Stillé, Charles J., *Major-General Anthony Wayne and The Pennsylvania Line in the Continental Army* (Philadelphia 1893); Johnston, Henry P., *The Storming of Stony Point* (New York 1900); Boyd, Thomas A., *Mad Anthony Wayne* (New York 1929); Preston, John H., *A Gentleman Rebel: The Exploits of Anthony Wayne* (New York 1930); Wildes, Harry E., *Anthony Wayne, Trouble Shooter of the American Revolution* (New York 1941).

GEORGE M. TODD.

Approved by General Wayne's great-great-great grandson, William Wayne.

WAYNE, James Moore, American jurist: b. Savannah, Ga., c.1790; d. Washington, D.C., July 5, 1867. He was graduated at Princeton University in 1808, was admitted to the bar in

1810 and engaged in practice at Savannah. He served for two years in the Georgia legislature, was mayor of Savannah in 1823, and was judge of the Superior Court in 1824–1829. He was a member of Congress in 1829–1835; and was appointed by President Jackson an associate justice of the Supreme Court of the United States, Jan. 9, 1835. He was a recognized authority on admiralty jurisprudence. He opposed the rechartering of the United States Bank.

WAYNE, village, Michigan, in Wayne County; altitude 660 feet; 17 miles southwest of Detroit; served by the Pere Marquette and New York Central railroads; and by a federal highway. Industries include the manufacture of motors, wire cloth, automobile bodies, and aircraft, truck equipment, tractor equipment, and hydraulic equipment. Wayne also is an agricultural community. The village was founded in 1824, and was incorporated in 1869. Government is by a council and manager. Pop. (1950) 9,372.

WAYNE, city, Nebraska, and Wayne County seat; altitude 1,455 feet; 100 miles northwest of Lincoln and 90 miles northwest of Omaha; on the Chicago and North Western; and Chicago, St. Paul, Minnesota, and Omaha railroads. It is in an agricultural region, in which the principal products are oats, corn, alfalfa, seed crops. Wayne makes extensive shipments of grain, hogs, poultry and eggs, cattle, hay and vegetables. It has the Nebraska State Teachers College, two high schools and public graded schools. Wayne was laid out in 1881, when the railroad from St. Paul to Sioux City was being built. Pop. (1940) 2,719; (1950) 3,595.

WAYNESBORO, wānz'bŭr-ō, city, Georgia, Burke County seat, altitude 261 feet, on the Central of Georgia and Savannah and Atlanta railroads; one federal and three state highways; 33 miles south of Augusta. The surrounding country grows pecans, asparagus, fruit, cotton, and field peas, and Waynesboro ships cotton and fertilizer. Veneers, lumber, canned vegetables, clothing and ginned cotton are the principal factory products; there is a steel fabricating plant. There is a Confederate monument here; and the Bowie house was the home of Rezin Bowie, brother of James Bowie, inventor of the bowie knife (q.v.). Named in honor of Gen. Anthony Wayne, the town was laid out in 1783, and incorporated in 1888. It has a mayor and council. Pop. (1940) 3,793; (1950) 4,461.

WAYNESBORO, borough, Pennsylvania, in Franklin County; altitude 713 feet; 20 miles south of Chambersburg; on the Pennsylvania, and the Western Maryland railroads. Apples and peaches are grown extensively in the county, and Waynesboro is a storage and shipping point for fruit. Its industrial plants produce textiles, shoes, metal fencing, structural steel, and heavy machinery. There is a public library. One of the original Mason and Dixon mileposts is preserved near by. Confederate forces passed through Waynesboro on the way to and from Gettysburg. The borough has council and manager. Pop. (1940) 10,231; (1950) 10,334.

WAYNESBORO, town, Virginia, independent of any county; altitude 1,295 feet; situated on the eastern border of the Shenandoah Valley, at the foot of the Blue Ridge Mountains, and at the southern end of the Shenandoah National Park; 12 miles southeast of Staunton, 96 miles northeast of Roanoke, and 124 miles northwest of Richmond. It is on the Chesapeake and Ohio, and the Norfolk and Western railroads; modern highways; and near the Skyline Drive, which extends along the crest of the Blue Ridge Mountains. Situated in a fertile agricultural area, which produces chiefly corn, wheat, hay, livestock, poultry, apples and other fruit, and has considerable dairying, it is a center of trade and industry. Its industries include the manufacture of rayon, silk, and woven fabrics, furniture, stoves, pumps, windows, organs, flour, feed, food, and dairy products, while it is also a center of apple packing and fruit processing. It has a modern public school system, and located here are the Fishburne Military School for boys, and Fairfax Hall, a preparatory school and junior college for girls. In the vicinity are many scenic attractions. About 14 miles southeast of Waynesboro, in the George Washington National Forest, is the Sherando Lake Forest Camp, a recreational center, with a 25-acre lake for bathing, hiking trails, picnic grounds, and the like.

The site of Waynesboro was first settled around the middle of the 18th century, and prior to the American Revolution a hamlet sprang up here on the trail across the Blue Ridge through Rockfish Gap to Kentucky and Tennessee. Gradually two rival towns grew up adjacent to each other, Waynesboro, named in honor of Gen. Anthony ("Mad Anthony") Wayne, of Revolutionary War fame, and Basic City, which continued a separate existence until 1923, when it was merged with Waynesboro. The Virginia Central Railroad, now the Chesapeake and Ohio, reached Waynesboro in 1854, and service by the Norfolk and Western was begun in 1882. During the Civil War the Battle of Waynesboro occurred at a ridge west of the town on March 2, 1865 (see SHENANDOAH VALLEY, MILITARY OPERATIONS IN). After a weak resistance, the greatly outnumbered Confederate forces, under Gen. Jubal A. Early, retreated in disorder, hotly pursued by Custer's Union cavalry as far as the south fork of the Shenandoah River and to Greenwood Station. Some 1,450 out of 1,800 Confederate soldiers and officers were captured, thus destroying General Early's army, while several miles of the Virginia Central Railroad in the vicinity of Waynesboro were destroyed. Waynesboro's growth was slow until the arrival of several new and important industries, beginning in the 1920's, following the discovery of its advantages as a manufacturing center, since when it has made rapid progress. It has council-manager government. Pop. (1940) 7,373; (1950) 12,357.

WAYNESBURG, borough, Pennsylvania, Greene County seat; altitude 1,035 feet; 40 miles south of Pittsburgh; on the Pennsylvania, and the Monongahela railroads. It is in an agricultural region, and in the natural-gas and oil belt. Its principal industrial products are brick, chemicals, and flour. There are stone quarries near by. The borough is the seat of Waynesburg College (q.v.). The settlement was laid out in 1796, and named for Gen. Anthony Wayne. Pop. (1940) 4,891; (1950) 5,514.

WAYNESBURG COLLEGE, Waynesburg, Pa., was founded in 1849. It was estab-

lished and is under the control of the Pennsylvania Synod of the Cumberland Presbyterian Church. It offers three regular courses, classical, literary, and scientific, which lead to the degrees of A.B., B.L., B.S., and A.M. for graduate work. It is coeducational.

WAYNFLETE or **WAINFLEET, William of** (WILLIAM PATYN, PATTEN, or PATTON), English prelate: b. Wainfleet, Lincolnshire, Eng., 1395; d. Aug. 11, 1486. The son of Richard Patyn, alias Barbour, he was educated at Oxford between 1426 and 1429. A favorite of Henry VI, he was appointed first headmaster of Eton College in 1442 and made second provost in 1443. In 1447 he succeeded Cardinal Beaufort as bishop of Winchester, a position he held the remainder of his life. He founded Magdalen Hall in 1448 and in 1558 Magdalen College (q.v.). From 1456 to 1460 he served as lord chancellor and took an active part in the privy council. Despite the fact that he had released Henry VI from the Tower on Sept. 29, 1470, he was generously treated by the Yorkists. He cooperated with Edward IV in the restoration of Eton College which was completed in 1480, received the king there the following year, and entertained Richard III in state in 1483. He endowed a free school at Wainfleet in 1484, and upon his death in 1486, was buried at Winchester Cathedral.

WAYS AND MEANS, Committee on, a partisan, standing committee of the House of Representatives which prepares all legislation regarding public finance, including taxation. It was first used in the Congress of 1789, and six years later became a standing committee. In 1850, it was given temporary right-of-way over other House committees, and during the Civil War, this privilege became permanent. Its 25 members are elected by the House and are approved by party caucuses. Chairmanship is given to one of the majority leaders, and approximately one third or one fourth of the members belong to the minority party. Majority and minority members frequently prepare separate bills for legislation.

WAYSIDE INN, formerly the home of an English family by the name of Howe, near Sudbury, Mass., about 20 miles from Cambridge. Also known as Red Horse Inn, founded 1686, it is the scene of Henry Wadsworth Longfellow's *Tales of a Wayside Inn* (q.v.). It was purchased by Henry Ford in 1923 and made into a Longfellow shrine.

WAYZGOOSE or **WAYGOOSE,** formerly wakegoose, a term for the annual festival in England given by a master printer for his employees in August to mark the beginning of the season of working by candlelight. It developed into a summer outing for all employees of a printing establishment.

WAZIRABAD, a town in Punjab, India, situated on the river Chenab, about 62 miles north of Lahore. A railroad connects it with Sialkot and Jammu. Nearby is one of the famous gardens in Punjab, and the great Alexandra Bridge over the Chenab is north of the town. Wazirabad is known for its cutlery, sword-sticks, and canes. Iron, steel, and boat-making are its chief industries. Pop. (1931) 20,707.

WAZIRISTAN, wä-zē-rĭ-stän′, independent tribal territory, situated west of the Suliman Range, north of Baluchistan, and east of Afghanistan. The country of the Waziris has at various times been the scene of military operations owing to the depredations and raids of the Waziris on the caravans transversing the Gomul Pass. The British government had maintained political agencies in both Northern and Southern Waziristan. The principal town is Kaniguram. It is a mountainous country, with much fine scenery, and a delightful climate except in some valleys. The Waziris, a portion of whom are known as Mahsuds, are a hardy race of Afghans and settled peaceably within part of India where they cultivate the land. Their crops are wheat, maize, and barley; they raise horses and sheep, and iron and wood are exported.

WAZZAN, wä-zän′ (Arab. for Ouezzane, wĕ′zän), French Morocco, an inland town, picturesquely situated on the steep northern slope of a two-peaked mountain, in the hill country 90 miles southeast of Tangier. It is a sacred city of refuge, and a place of pilgrimage, the headquarters of the grand sherif, the spiritual ruler of Morocco. The principal buildings are the great mosque and the tombs of a long line of sherifs. The trade is, as elsewhere in Morocco, in the hands of the Jews. Pop. (1936) 16,442; (1941 est.) 20,230.

WEA, a tribe of the Algonquin stock of North American Indians, belonging to the Miami confederacy. The name is probably a contraction from various words meaning eddy current, Wawiaqtenang, Wayahtónuki, or wayaqtonwi. The Algonquins named Detroit Wawaqtenang. When first known to the whites in 1672–1703, they were in Wisconsin, but they seem to have gradually drifted southward, and in 1701 one of their villages was on the site of the present Chicago, Ill., and in 1719 their chief village was on the Wabash below the mouth of the Wea Creek, in Indiana. They were hostile to the whites in western Virginia, in which their country was situated, but they finally signed the celebrated treaty at Greenville, Ohio, on Aug. 3, 1795. In 1820 they sold their last lands in Indiana and moved with the Piankashaw to Illinois and Missouri. In 1832 they again sold their lands and the main body moved to Kansas. Rapidly decreasing, the Wea and the Piankashaw united with the Peoria and Kaskaskia of the Illinois confederacy in 1854; at this time their population aggregated 259, largely mixed-bloods. In 1868 they moved to the Neosho Indian Territory, now Oklahoma, where the small remnant has been absorbed.

WEAK ENDING, also called FEMININE ENDING, in poetry, a verse ending with an unstressed syllable such as a preposition. A light ending is one in which the line ends with a pronoun or auxiliary verb.

WEAKFISH, or **SQUETEAGUE,** a spiny-rayed fish of the genus *Cynoscion* and family Otolithidae. It has no teeth on the vomer or palate bones, but numerous ones in the jaws, which are weak in structure; the air-bladder

has a horn on each side projecting forward. The genus is chiefly American, with about 15 North American species. The common weakfish (*C. regalis*) is one to two and one half feet long, brownish blue above, with irregular brownish spots, and tinged with greenish and banded in the young; the sides silvery, abdomen white, and iris yellow; lower fins orange; a single row of very small teeth in the upper jaw and a double series in the lower; dorsals separated, and the second, with the caudal and anal, mostly covered with scales. This is one of the most abundant fishes along the entire Atlantic Coast from Cape Cod to Florida, but there have been times when the invasions of bluefish have driven them from parts of the coast. The name originated from the little resistance it makes when taken, and from the ease with which the delicate structure of the mouth enables it to break away. This is the name most employed on the New Jersey Coast, while in New England the Indian name "squeteague" is usual, and in the South, sea trout is applied to this and to the spotted *Cynoscion*. On the New Jersey Coast it appears early in the spring, being most abundant toward the end of July, and disappears late in the autumn; it is a greedy biter, and is easily taken by any soft white bait, affording great sport for about an hour on the flood tide; it swims in shoals near the surface and requires a line slightly if at all leaded. In summer it is abundant about the mouths of rivers, where the water is brackish, and sometimes ascends far up, having been taken in the Hudson 50 miles above New York; it is taken by seines and poundnets in large quantities; when caught it makes a croaking sound, also heard when the fish is at the bottom.

WEALDEN, wēl'dĕn, certain delta deposits of the Cretaceous system, from their great development in the weald of Sussex, England. Weald means in Old English a wood or forest, and the name is applied to a tract of country lying between the north and south downs of Kent and Sussex. The recognized geological name of this subdivision of the Cretaceous system is the Neocomian, from the old Latin name of Neuchâtel in Switzerland. This stage in the south of England, and thence eastward across Hanover, consists of a mass of sand and clay, sometimes 1,800 feet thick, representing the delta of a river. Only a portion of this delta remains, but as it extends in an eastern and western direction for a distance of at least 200, and from north to south less than 100 miles, its total area may have been 20,000 square miles, indicating a very large river flowing from a continent. See GEOLOGY.

WEALTH. Wealth comprises all material things owned by individual human beings or their associations or other agencies. The reason for ownership lies in two general characteristics of wealth: its capacity to satisfy the wants of the possessor, directly or indirectly, currently or in the future, and its scarcity. No effort is made to own material things having no known or suspected capacity to satisfy wants; and such things are not wealth. Not all material things capable of satisfying wants, however, are wealth; for, unless they are scarce in comparison with the aggregate of wants which they help to satisfy, no purpose is served by owning them. Thus, some things which nature provides freely exist in such abundance that all human beings can enjoy all they want of such things and their services. But most things provided by nature are not thus abundant, and they are therefore appropriated and owned so that the owners may enjoy their benefits exclusively. Thus land, and the various natural resources which lie upon or beneath land, are not sufficiently abundant to meet all the wants of all people; and they are therefore appropriated and become wealth. Under the above definition, a human being is wealth; but, for various practical reasons, in speaking of the wealth of a nation or of an individual or group of individuals, this literal implication of the definition is disregarded, and human beings are not counted as wealth.

The word material in the definition is significant, for it excludes from wealth a long and important list of things which are called services and do meet wants but are used up as soon as they are created. The material things which constitute wealth fall into two broad but somewhat ill-defined categories. Items in the first category are capable of satisfying human wants directly, and are generally called consumption goods. Items in the second category are, with some reservations, capable of satisfying wants only indirectly, and are generally called production, or producers' goods because they must be subjected to or play a part in one or more productive operations before they are available for direct consumption.

Nearly all items of wealth—the most important exceptions are unimproved land and undeveloped natural resources—are in some degree the result of production, the process which adapts their location or form or other qualities to human use either in direct consumption or in the production of still other goods. The stock of production goods is combined with human labor in a vast number and immense variety of activities which together make up the total system of production. The output of this system consists entirely of services which are used up either in consumption or in further production as they are produced, and of material things which are in truth new items of wealth although some of them may survive as wealth for only a brief interval before they are used up in direct consumption or in further production.

In all modern societies most production is carried on by groups of individuals, some of whom provide labor, ranging from the lowest grade of unskilled physical exertion to the highest type of leadership activities, and some of whom provide wealth in the form of production goods. How these various participants shall share in the services and wealth created by their joint activities is a question of the greatest difficulty and the highest importance to all citizens who shape or seek to shape social policy. The issues posed by this question are greatly aggravated by the fact that possession of wealth, and thereby control over production goods, is much less widely and less evenly spread among men than is the capacity to perform all labor except that requiring exceptional skills and especially, that of planning and managing. The issues are further aggravated by the institutional arrangements which have largely obscured or rendered impersonal the participation in production by the owners of wealth, especially the very numerous owners possessing only small amounts of wealth. Among these arrangements we must note par-

ticularly those which tend to conceal the very nature of the wealth which individuals possess. In fact, the definition of wealth given above by no means describes the word wealth as it is commonly used in speaking of the possessions of an individual. Progress in the organization of the production process, aiming toward a greater or more efficient production of new wealth through the use of available labor and production goods, has been aided greatly by the willingness of individual owners of the material things which constitute real wealth to transfer physical possession and partial or temporary control over the use of such wealth, to other individuals or to corporate groups of individuals, in return for claims represented by paper evidences of ownership or of the obligations of debtors. These paper claims, some of which are in forms and most of which can be exchanged by trades among their several owners, which pass as money then become part and in some cases nearly all of what is called the wealth of such individuals. Their real wealth has been transferred to others; and the corresponding claims in the form of money or property rights, which they possess have little power to convince the ignorant that these owners of wealth do in fact contribute vitally to production.

W. L. Crum,
Professor of Economics, Harvard University.

WEALTH, National. The wealth of a nation is the stock of economic goods owned by its inhabitants either in their capacity as individuals or as member of the national group. Defined in this way wealth consists of the aggregation of substantive things called economic goods. The definition may be broadened or narrowed by modifying the content of economic goods. The wealth of a nation as distinguished from its income is, then, the stock of economic goods owned as of a specific date by those domiciled within a nation; while the nation's income is the economic goods consumed during the income period, by those domiciled there, plus the net additions to their wealth resulting from the income-producing process. Thus wealth is a *stock* while income is a *flow* of economic goods.

Economic goods defined most broadly include all sources of satisfaction which are scarce and therefore able to command a price. They include not only objects external to individuals but individuals themselves, or, at least, their useful capacities. Generally, however, wealth is restricted to those economic goods which are external to the owner so that individuals and their capacities are excluded. Furthermore, only material economic goods external to the owner are ordinarily included. Such things as the reproductive power of seeds; the "good will" of a firm, or the acumen of its management; the life supporting qualities of sunshine; the efficiency of organized institutions; are excluded except in so far as they are reflected in material objects.

Irving Fisher's definition of wealth as, "material objects owned by human beings and external to the owner" is the general connotation given the term in economics. For many interpretations of national productiveness, however, the concept of the resources of a nation (its wealth, broadly speaking) must be extended to include the number and capacities of its population, the efficiencies of its functioning institutions, and the life promoting and sustaining power of its climate.

This view of wealth, in either its narrow or broader aspects, places emphasis on the substantive items which compose it. The ownership rights in such items which govern the use, enjoyment, and disposal of their services are often spoken of as "claims" on wealth. A share of stock, a bond, a bank deposit, or paper money are tangible instruments which give "rights" to wealth. Individuals often speak of them as wealth *per se*. The right to use a public park or library is also a claim on wealth. Since all wealth must be owned by individuals either as individuals or collectively as members of a social group it is perfectly sound, for some purposes, to speak of ownership claims as if they were wealth. In order not to count the same things twice we would then have to exclude the substantive items themselves. It has seemed preferable to economists to think of the substantive items as the wealth and the "rights" to the use and disposal of the services of these items as claims on wealth. It must be recognized, however, that the arrangements by which wealth is owned and its uses facilitated are in themselves part of the institutional framework within which the economy of a nation functions and that these arrangements have pertinence and usefulness in themselves.

Measurement Difficulties.—The measurement of wealth, like the measurement of income, requires that the heterogeneous content of substantive items be valued in common terms so that they may be added to form a single comprehensive total. This is usually accomplished by estimating their money values. Such estimates, even for a single year, are difficult. The value of an item of wealth may be viewed in two ways. First it can be thought of as the price which can be received for the use of the item for a restricted period of time, say a year, the item to be returned intact; or, second, as the purchase price which gives the buyer the right to use or otherwise dispose of the services of the item for the entire period of its usefulness. These two values are not distinct but are closely related. The purchase price, which is what is usually meant by the value of an item of wealth, is, excluding sentimental factors, nothing more than a present value assigned to an estimate of the use value of the item for the period of its usefulness. Any present value of future services involves discounting these anticipated services at a current interest rate. Sales values of wealth are thus seen to be reflections of anticipated service values, that is, of expected income.

If each item of wealth was sold currently the prices (market values) thus established could be taken as appropriate values. This seldom happens. It becomes necessary, therefore, to assign to the stock not sold the prices secured for the units that were recently transferred. For some items of wealth such as public roads, parks, or even many factory buildings, no representative items are transferred, so that some appraised or book value must be assigned. Book values are usually original purchase price values and these may be quite different from either the current costs of producing a similar item or the price at which the item could be bought or sold. Where marketable instruments such as stocks and bonds exist as ownership claims against the property, the market values of such instruments constitute still another basis for valuing wealth and generally are quite different values.

Current practice in wealth estimating is to se-

cure, as nearly as possible, current market value. Even if these are obtained the task is only half over if time comparisons are to have any significance. Since the value of money changes, wealth measured in money values would not tell us whether the total of substantive wealth (useful resources) had increased or decreased in quantity. To answer this question we would have to express the totals in dollars of constant purchasing power. For this reason most of the historical estimates of wealth have only limited usefulness since they do not provide the information by which they can be made comparable.

Two major categories of substantive wealth, reproducible and non-reproducible wealth, present somewhat different aspects and difficulties for the estimating of money values. Reproducible wealth, which is generally destructible as well, is composed of things which man has made and which he can make again—or he can make closely similar things. The market value of this type of wealth tends, under competition, to equal its cost of reproduction. At any given time the market values of reproducible wealth may deviate widely from reproduction costs. But competition, by increasing or decreasing the quantity of such items, tends to bring their market values into equality with reproduction costs. To secure a measure of the changing quantity of reproducible wealth over time we can select (1) their reproduction costs, (2) their market values, or (3) their original costs, adjusting each to a given base year of costs for comparability over time.

Thus, for reproducible wealth it is clearly permissible to talk of an increasing or decreasing quantity of substantive wealth irrespective of how difficult it may be to measure such changes in the composite of all such items. For non-reproducible wealth it is equally clear that we cannot properly speak of an increase in the quantity of such wealth since by definition it cannot be produced. Land is the major item in such wealth and if, as is customary, we include under land all natural resources, it encompasses the total of non-reproducibles with the minor exception of produced works of genius which are unique and therefore not replaceable.

Ricardo spoke of land as the "original and indestructible properties of the soil" but our definition of land as all natural resources certainly includes things which are destructible. The various minerals and other ingredients available in nature, while not produced, are certainly destroyed, at least in form, by use. While their quantity may not be increased, it can be decreased. The measurement of such resources for quantification over time presents almost insuperable obstacles. While strictly speaking the quantity of such resources in existence may not be increased, they may be discovered from time to time or, if known, may be brought into use gradually with the expansion of the economy. These considerations raise the questions whether such discoveries and inclusions in productive uses should be considered additions to the stock of wealth and whether the depletion of known resources should be subtracted.

For many purposes the addition of newly discovered national resources are important considerations as are the exhaustion of known minerals and the expansion of useful areas. Such resources are in part substitutes for reproducible wealth and certainly increase the output of the economy. Their measurement in terms of money values is so difficult, however, that they should generally be treated separately from the measurement of reproducible wealth.

The measurement of wealth is subsidiary to the measurement of income. The national income is a much more direct index of the success and efficiency of an economy and also of the basis upon which its wealth, broadly or narrowly defined, is really evaluated. The value of wealth is nothing more than the reflection of its income contributing power, and no item can meaningfully be included in the category of wealth.

Measurement.—A presentation of the national wealth of Great Britain, 1932–1934, was arranged by Professors Hicks and Hart in their book entitled *The Social Framework of the American Economy,* to bring out the major categories of wealth, their market values, their relationship to wealth claims and how double counting is avoided. Their tabulation, including the note prepared by Hicks and Hart, is shown as Table 2.

In addition to indicating the wealth of Great Britain as totaling something like 18,700 million pounds it shows the main categories of which the wealth was composed. Claim items (bonds, government debt, mortgages) are shown to cancel out. The assets which are cancelled by corresponding liabilities are indexed by the small letters a, b, c. The national wealth is thus seen to be either, (1) the total value of all material assets (all those assets not preceded by a small letter) plus the net foreign investment, or (2) the sum of the net assets of private persons and government. These two concepts are clearly equivalent since all tangible property is owned by the members of the economy and constitute, after adding net foreign claims, their net assets.

Two additional points require comment. First, wealth owned directly by the government is seen, in this instance, to be less than government debt. This can only mean that the deficit is a lien upon the net assets of the individuals taken collectively. It is cared for by subtraction in the net assets column. Second, money (except gold and silver) and bank deposits are not included among the accounts because such items are merely claims which must, in total, cancel each other. If individuals have money on hand, it appears in their assets column, but the government, (or the government and the banks) must have liabilities in equal amount. Similarly, bank deposits which are assets to individuals are liabilities to banks and cancel out.

A preliminary estimate of reproducible wealth for the United States for 1946 (unpublished manuscript by Marvin Hoffenberger prepared for the Conference on Research in Income and Wealth, National Bureau of Economic Research, New York) is shown in Table 1.

Table 1.—REPRODUCIBLE WEALTH OF THE UNITED STATES, 1946
(millions of dollars)

Residential Buildings	$ 56,000
Other structures including equipment, roads and other government property	320,000
Inventory	76,000
Livestock	12,000
Consumers' goods	80,000
Monetary gold and silver	23,000
Total	$567,000

More significant, since it deals with the growth of wealth in terms of constant prices, is an estimate of reproducible wealth, other than

Table 2.—THE NATIONAL WEALTH OF GREAT BRITAIN, 1932–1934 (millions of £'s)

	Assets		Liabilities		Net assets
Private persons, including farmers	Houses	3,500	[a] Due to building societies, etc.	500	———
	Other durable-use consumers' goods	700			
	Agricultural land	600			
	Farm equipment	400			
	Foreign investments	1,500			
	[c] Government Debt	2,500			
	[b] Shares, bonds, and other obligations of British firms	14,000			
Total property of private persons		23,200		500	22,700
Firms	Buildings and land	1,000	[b] Shares, bonds and other obligations	14,000	
	Railways	750			
	Other industrial and commercial equipment	8,000			
	Gold	250			
	[c] Government Debt	3,500			
	[a] Mortgages on house property, etc.	500			
Total property of firms		14,000		14,000	0
Government and other public bodies	Land and buildings	600	[c] National Debt	6,000	
	Other equipment	1,400			
Total public property		2,000		6,000	—4,000
Total national wealth					18,700

Note to preceding table: The figures in this table are based on H. Campion, *Public and Private Property* (Oxford University Press, 1939), particularly pp. 65 and 84. In order to fit Mr. Campion's figures into the accounting form suitable for our purposes, I have had to make some extra guesses, which do not claim to be more than guesses, though I think they are reasonable. (1) Mr. Campion gives £4,600 millions for the total of private houses and buildings used for business purposes taken together. I have divided this, with an eye on the valuations for taxes. (2) The Colwyn Committee estimated that holdings of the national debt were divided between firms and private persons in about equal shares; holdings by firms were probably larger in 1932 than in 1927, so I have made an adjustment to allow for this.

The following points should also be noted: (1) Armaments and roads are not allowed for in Mr. Campion's estimate of public property. The reader is at liberty to make an addition to the national capital to allow for these, if he so chooses. (2) The foreign investments included among the national assets are net obligations due from outsiders. Material property owned by British firms in other countries (branches, subsidiary companies, etc.) is included among the material assets of firms. (3) The external debt of £1,000 millions or so to the American government was not being paid after 1931, so it is neglected. An American would be within his rights if he deducted £1,000 millions from our estimate of the national capital on account of this debt. (4) Gold in the Exchange Fund has been added to gold in the Bank of England; but that makes it all the more of a question whether both of these institutions should not be reckoned among *public bodies*, rather than among *firms*. It should be noted that these stocks of gold were largely increased during the years 1933–1938. (5) Holdings of national debt by public bodies are cancelled out, so they do not appear in the table.

household, for years at decade intervals from 1879 to 1939, inclusive. This estimate (presented in Table 3) was prepared by Simon Kuznets and is based on capital formation data tied to several direct estimates by the Bureau of the Census and the Federal Trade Commission. All values are expressed in 1929 prices.

Table 3.—REPRODUCIBLE WEALTH OF THE UNITED STATES, OTHER THAN HOUSEHOLD, 1879–1939, 1929 PRICES

(millions of dollars)

Beginning of year	Real estate improvements and equipment	Inventories	Balance of foreign claims	Total reproducible wealth
1879	$ 29,968	10,554	—1,700	38,822
1889	51,157	16,188	—4,700	62,645
1899	86,511	20,073	—5,500	101,084
1909	132,064	26,063	—5,700	152,427
1919	177,299	35,201	2,400	214,900
1929	227,744	47,211	8,000	282,955
1939	236,454	46,528	4,600	287,582

Source: Simon Kuznets, *National Product Since 1869*, National Bureau of Economic Research, New York 1946; Table IV 10, Part B, page 228.

Reproducible wealth in the sixty-year period covered by Table 3 (exclusive of household wealth such as furniture, clothing, jewelry, and personal automobiles; and probably with only incomplete coverage of public wealth) increased almost seven and one-half times. The percentage rise in each decade varied, but was considerably greater in the early decades than in the later ones. Decade by decade the percentage increases were 61, 61, 51, 41, 32, and 2. The last decade shows the severity of the depression during the 1930's. If changes are measured over 20-year spans retardation in the rate of increase is equally obvious. The rise 1879–1899 was 160 per cent, 1899–1919 was 113 per cent, and 1919–1939 was 34 per cent.

The measures of wealth given are estimates subject to considerable error but they probably give fairly accurate indications of the growth of the wealth totals over the period surveyed. It is informative to compare these United States wealth measures with those for the growth of population. For the census decades 1880 to 1940 the percentage increases over the preceding census were as follows: 25.5, 20.7, 21.0, 14.9, 16.1, 7.2. It is clear then that wealth per capita, except for the last decade, must have shown significant increase. Reproducible wealth, in prices of 1929, increased from $750 per capita in 1879 to $2200 per capita in 1939, or approximately a three-fold increase. Since the portion of the population in the labor force did not change significantly over this period, each available worker in 1939 had about three times as much wealth as a worker in 1879 to aid him in the production of the national income. This estimate agrees substantially with the findings of Paul Douglas (*The Theory of Wages*), namely, that each man-hour of manufacturing employment in 1922 had 2.7 times as much fixed manufacturing capital (wealth) combined with it as had been true in 1890.

Information in Colin Clark's, *Condition of*

Economic Progress, allows some international comparisons of wealth and income per member of the working population in 1913. Table 4 summarizes this information and shows the relationship between wealth and income. The last two columns of Table 4 express the per worker wealth and income of each country as a percentage of that for the United States. That wealth and income are related is clearly shown, although there are significant discrepancies. The content of the income and wealth figures would require close inspection and analysis to separate the apparent disparities from the real ones, and cannot be entered into here. The conclusion that a larger income per worker implies a larger amount of wealth per worker is clearly indicated.

Table 4.—INCOME AND REPRODUCIBLE WEALTH PER HEAD OF THE WORKING POPULATION FOR SELECTED COUNTRIES IN 1913 IN I.U.'S

Country	Reproducible wealth per head of working population	Real income per head of working population per 48 hour week	Percentage of wealth per head in each country to U.S.A.	Percentage of income per head in each country to U.S.A.
U.S.A.	$5,160	$1,191	100.0	100.0
Canada	4,590	1,061	88.9	89.1
Australia	4,100	742	79.5	62.3
Britain	3,590	966	69.6	81.1
Germany	3,130	704	60.6	59.1
France	3,060	629	59.3	52.8
Sweden	2,680	474	51.9	39.8
Belgium	2,190	470	42.4	39.4
Austria	1,580	452	30.6	37.9
Japan	460	128	8.9	10.7
Japan, 1930	980	301	19.0	25.3

Source: Colin Clark, The Conditions of Economic Progress, Macmillan, London, 1940, p. 389. For definition of I.U.'s see article on National Income.

The accumulation of reproducible wealth results from the consumption of less than each year's full national product (national income). The difference between national income and consumption is called net capital formation. Gross capital formation includes net capital formation plus the replacement of productive facilities worn out during the income period. In the United States during the period 1869–1939, net capital formation in constant prices is shown by Kuznets (*National Income: A Summary of Findings*) to have ranged from about 16 per cent to 1.4 on the basis of average annual amounts for decades overlapped by five years. The 1.4 per cent rate applies to the decade 1929–1938 and shows the severity of the depressed conditions during that decade. If the period 1869–1928, which excludes the depressed 30's, is divided into three periods of roughly 20 years each, Kuznets finds that the percentage of net capital formation is 15.0, 15.7, and 12.2, respectively. This indicates a modest decline in the rate of capital accumulation exclusive of the influences of the 30's.

A saving of 12 to 15 per cent of national income in the United States during the period between the Civil War and World War I appears to be a modest amount, particularly in the light of the expansion of national income by almost eight times during that same period while population expanded three times. It is significant that between 85 and 87 per cent of the national income was used for the purpose of satisfying consumers' wants, indicating the better maintenance of the people who make up the nation. Furthermore, the expansion of national income seems to imply that it may have had production influences as well. As noted earlier, the wealth of a nation in its broadest sense includes the people of the nation and their capacities. A better provided for, better educated population is an addition to wealth in even a larger sense than the growth of a stock of material goods. Also during this period the United States benefited by the development of its natural resources and by the growth of its population not only by reproduction but by the addition of immigrants from abroad who came here mainly at the beginning of their working years.

These latter points concerning the wealth of a nation in its broadest sense are well summarized by Kuznets in *National Income: A Summary of Findings.* He writes, ". . . two important factors, not directly reflected in the percentages net capital formation constitutes of national income, should be noted. First, through most of the period the country profited from large immigration. The capitalized value of this addition to the country's productive population was estimated to be more than $10 billion per year in the periods of largest immigration (1881–1890 and 1901–1914), and through the period 1860–1930 at roughly $6 to $7 billion per year, at prices of the 1920's (see calculation by Dr. Agostino de Vita, supplementing the article by Corrado Gini, Europa und Amerika: Zwei Welten, *Weltwirtschaftliches Archiv,* July 1940, v. 52, pp. 31-35). Second, through a substantial part of the period the country profited from availability of land for extensive expansion within its own boundaries." (Simon Kuznets, *National Income: A Summary of Findings,* National Bureau of Economic Research, New York, 1946, f.n. p. 52.)

RAYMOND T. BOWMAN,
Associate Professor of Economics, University of Pennsylvania.

WEALTH OF NATIONS. "In the year 1776, Adam Smith published his *Wealth of Nations;* which, looking at its ultimate results, is probably the most important book which has ever been written." Thus states Henry Thomas Buckle concerning the great work of the leader of English "Classical Economists." Since Smith deals with both political philosophy and economic theory, it may increase the clarity of an

analysis to treat these two phases of his doctrines separately, though always remaining conscious that in Smith's mind they formed a single unified and coherent body of thought.

In his political theory Smith followed the teachings of Locke, Montesquieu and Hume, combined with the doctrines of the Physiocrats regarding the proper scope of state activity. It is his concern with the latter which is of the greatest importance in this analysis, as he here exerted his greatest influence. Accepting the doctrine which the Physiocrats had taken over from contemporary scientists and *philosophes,* namely, that there is a natural and beneficent order which pervades the universe and of necessity extends to the domain of social, economic and political phenomena — an order which man cannot and therefore should not attempt to alter — Smith launched a violent attack upon the restrictive state activity which had been advocated by the Mercantilist writers who had dominated political and economic theory and practice for more than a century prior to 1776. It was his fundamental thesis that human happiness and the «wealth of nations» can be most rapidly and effectively increased by bringing about complete industrial and commercial liberty, and it was at this point that his political philosophy merged with his economic theory and made possible a unified and coherent body of doctrine, though it prevented Smith from separating politics from economics as effectively as he had divorced ethics from economics. Smith enumerates the three classes of duties which it falls to a state to perform, or to guarantee the execution thereof and beyond which it should not proceed. These are (1) the protection of the citizens against foreign states; (2) the administration of law and justice; (3) the establishment and maintenance of public works and the provision of education, academic and religious. But he would have even the last two types of functions exercised as far as possible by the citizens acting voluntarily according to self-interest, and the state should only intervene in these fields when voluntary activity fails to function in an effective manner. It is needless to add that he vigorously urged the immediate abolition of all restrictive state regulation of industry and commerce and the immediate initiation of that régime of unhindered competition which would allow economic affairs to harmonize with the beneficent order of nature and bring the full measure of happiness and prosperity to the human race. These *laissez-faire* theories were adopted and re-emphasized by Smith's disciples and were the leading factor in securing that abolition of industrial and commercial restrictions which constituted that era of «economic liberalism» and «political individualism,» which was the most fundamental characteristic of the economic and political history of Europe during the first half of the 19th century, and which still prevailed a century after the publication of the 'Wealth of Nations.'

In his strictly economic doctrines Adam Smith has had as wide an influence as through his political theories. Though not the founder of modern political economy, he was its first great systematizer, and the 'Wealth of Nations' stands toward modern economics in much the same way that Comte's 'Positive Philosophy' does to present day sociology.

The most conspicuous element in Smith's system of economic doctrines was his emphasis on the factor of *labor,* which he conceived to be the ultimate source of all wealth and the true measure of value. In his theory regarding the production of wealth his emphasis upon the importance of the division of labor has been most influential in the history of economic thought. Smith's treatment of this subject was the first extensive analysis it had received since the appearance of the 'Republic' of Plato, and in many respects it has never been improved upon. Smith's analysis of value and exchange centred about the well-known labor theory of value, and he maintained that the actual measure of value was the quantity of labor which a given commodity would command in exchange. His theory of distribution initiated the conventional discussion of wages, profits, interest and rent. Wages are the return to labor and are determined by the demand for, and the supply of, labor. Profits are the return to capital and are determined by the amount of capital stock invested, varying inversely in proportion to the amount of the stock. Interest is that part of profits which is derived from the lending of capital. Finally, rent, and here in part he anticipated Ricardo, is the return to the landowner and may exist as soon as all free land is occupied. It normally equals the residue from the gross income of the renter after he has deducted profits and wages. Though these specific phases of economic analysis in the 'Wealth of Nations' were of great importance for the subsequent development of economic theory, they have scarcely stood the test of more refined and scientific analysis, and they have done far less than his more general contributions to secure for Adam Smith the pontifical position which he still occupies in the history of economic thought. This position has been attained by his epoch-making attack upon Mercantilism; the accompanying advocacy of the initiation of the régime of *laissez-faire* and unhampered industrial competition; and his production of the first great systematic treatise on political economy. The significance of the 'Wealth of Nations' for posterity has been thus expressed by Walter Bagehot, «The life of almost every one in England — perhaps of every one — is different and better in consequence of it. No other form of political philosophy has ever had one-thousandth part of the influence on us.» Consult Gide and Rist, 'History of Economic Doctrines' (Chap. II); Haney, L. H., 'History of Economic Thought' (Chap. X); Bonar, 'Philosophy and Political Economy' (pp. 146–183). The relation of the 'Wealth of Nations' to sociology is presented in A. W. Small's 'Adam Smith and Modern Sociology.'

Lecturer, New School for Social Research, New York City.

WEANING, the accustoming of an infant to food other than its mother's milk, or the disengaging of a child from the habit of nursing. In normal cases it is now deemed desirable to continue nursing for nine or 10 months after birth Very careful mothers extend the period to cover the second summer. With

children who are healthy, and cut their teeth early, weaning may begin earlier than with weak, sickly children. It should never be attempted during sickness, nor, unless absolutely necessary, in hot weather. It is best for both mother and child to bring it about gradually. By so doing the secretion of milk in the former is slowly diminished, and those complaints which arise from sudden weaning are prevented; while the child is gradually accustomed to other kinds of sustenance, and the restlessness and want of sleep, which are so troublesome in sudden weaning, are avoided. Both during the weaning and for some time after it no food should be given to the child except what is very easy of digestion, and more fluid than solid, and in particular what has no stimulating qualities, nor any that will tend to create acidity, or produce other marked changes in the organic function. See INFANCY.

WEARE, wār, **Meshech,** American colonial leader: b. Hampton Falls, N.H., June 16, 1713; d. there, Jan. 14, 1786. He was graduated at Harvard in 1735; studied theology and entered the ministry, which he gave up for the practice of law; was repeatedly sent to the legislature, and in 1782 was speaker. His later appointments included that of commissioner to the Albany Congress (q.v.) in 1774, justice and (1777) chief justice of the Superior Court of Judicature. He was also colonel of a militia regiment, and when the Revolution opened was appointed chairman of the Committee of Public Safety. Upon the reorganization of the state judiciary he was placed at its head. He raised troops for defense against Burgoyne, whose invasion he materially aided in repelling. In 1776, under the temporary constitution, he was elected president of the state, and was annually re-elected until 1784. Under the new constitution he was again elected president, but resigned before the expiration of his term.

WEASEL (*Putorius noveboracensis*), a fur-bearing mammal (q.v.), typical of the family Mustelidae. The body is elongated and slender, the head long, the legs short, the muzzle rounded and the tail short and slender. The feet have each five toes and are digitigrade and unwebbed. There are 34 teeth and the sectorial or flesh-tooth lacks an internal tubercle. The anal glands are developed and secrete a strong-smelling substance. The weasel attains a length of from 12 to 15 inches, of which the tail makes nearly one third. The male is larger than the female. Above, the color is brown; below, white or pale yellow the terminal one third of the tail black. In winter the fur becomes more or less white, but this change is complete only in the north and does not affect the black of the tail; in this white phase the animal is called an ermine (q.v.). The common weasel, in one or other of its varieties, inhabits the entire eastern United States, westward to Minnesota, south to North Carolina and north to Canada; and is replaced in most other parts of North America by more or less closely related species and in Eurasia by others, of which the Siberian ermine is its nearest ally. Owing to its retiring and nocturnal habits it is unknown to most people. It is plentiful even in the vicinity of large cities, where it renders efficient service in the destruction of vermin.

The European weasel (*P. vulgaris*) is slightly smaller than its American relative, reddish brown in color, but whitish underneath. (See POLECAT). The weasel is a highly courageous animal, and makes war on rats, mice, hares and rabbits, birds and many other small animals. During the summer it devours insects, but appears never to partake of a vegetable diet. Instances are on record in which these animals have attacked horses and cows, and they sometimes exhibit an utter indifference to the proximity of man. They are especially fond of eggs, and rob hen roosts and the nest of every wild bird which they find. Their mode of killing their prey is characteristic—since they usually fasten on to the neck of their victim, and hold firmly on while they suck the blood; next they eat the brains and only then the flesh. Like most of their near relatives they often kill much more than they require for food. They hunt by scent and are tireless in pursuit. Few animals are so active, and the slimness of their bodies enables them to explore every hole and hiding place of their prey. Weasels live in holes under stone walls, rocks and trees, in burrows captured by force from ground squirrels and woodchucks, in hollow stumps, etc. A nest of dried leaves and grasses is constructed and about five young are born in a litter. Consult Coues, *Fur-bearing Animals* (Washington 1877); Merriam, *Synopsis of the Weasels of North America* (Washington 1896).

WEATHER BUREAU, a United States government agency responsible under federal law for the maintenance of the national weather service with its organized network of stations. It is a bureau of the Department of Commerce. There are similar organizations in foreign countries operating under various names, as for example the Meteorological Service of Canada, Department of Transport. These organizations cooperate in the exchange of observations and other meteorological information to their mutual benefit.

General Functions.—The Weather Bureau's present network of about 10,000 reporting stations of all kinds, as of June 1, 1947, of which 418 are first-order stations manned and maintained by full-time civil service employees, provides the basic observational data required, both surface and upper-air, in as complete detail as is practicable. The observations are collected, charted, and analyzed to make them available to the public as weather forecasts, weather maps, storm, hurricane, and flood warnings, and in the final form of climatological summaries and other publications; all for the benefit of industry, air, land and water transport, commerce, business, engineering, agriculture, and many other national interests.

Research.—The Weather Bureau is also charged with the responsibility for research in atmospheric phenomena, especially as developed by upper-air observations and the resulting air-mass analyses. Among the considerable number of investigations currently in progress, mention will be made of solar radiation measurements; studies of the physics of thunderstorms; studies of icing on aircraft; investigations of changes in the ozone present in the upper atmosphere to determine the relation of such changes to large-scale movements and frontal developments of air masses; the invention, design, and testing of new instruments and apparatus, especially for measurements of cloud height (or ceiling), visibility,

and for upper-air soundings, also the improvement of older forms; the development of automatic weather stations for use in remote locations to transmit wind velocity, direction, relative humidity, temperature, and pressure by radio or wire to a central office; studies of precipitation intensities and their relation to runoff and flood control in selected watersheds; and numerous statistical studies in connection with storm movements, climatology, etc. These research projects have as their main objectives the improvement of forecasts for both short and long periods, largely for the benefit of rapidly-expanding and worldwide aviation, a better knowledge of the atmospheric circulation, an improved knowledge of the evolution of storms and allied phenomena, and a greater usefulness to the public of meteorological information in general.

The Weather Bureau has very broad authority of law for promoting the development of the science of meteorology. Research to that end has always been carried on by the bureau personnel although to a somewhat limited extent until recent years, for the bureau is essentially a service organization. Hence its activities have been directed very largely toward the development of its many services. As evidence of the valuation placed upon the work of the bureau, Dr. F. W. Reichelderfer, chief of bureau, was the recipient of the Robert W. Losey award for 1942, given because of his pioneering work and continued activity in advancing the science and practice of meteorology as applied to aeronautics, with particular recognition of the development under his direction of the network and system of upper-air soundings by radiosondes. The bureau has undertaken (1947) a project of large magnitude to study the causes and mechanisms of thunderstorms, with assistance from the military weather services and other agencies that have concern for research in this direction. The bureau is also engaging in fundamental studies of solar radiation, of the electrical influences that seem to be part of all cloud and precipitation formations, and of the use of radar for weather observing and forecasting.

History. — Keen observers and scientists knew in the 17th century that storms in our country along the Atlantic seaboard frequently moved northeastward to New England from some location in the southland, attended by strong northeast winds and heavy precipitation in advance of the storm center. But there could be no comprehensive study of such a storm with the plotting on a chart of atmospheric pressures, temperatures, etc., until suitable observations all made at the same time along the path and throughout the area covered by the storm could be secured. The value of forecasting such a storm was seen, but it was not until the invention and use of the telegraph in 1837 that such a chart and forecast even became possible. Some sporadic attempts were made before 1870 to do so, but such a development awaited the establishment of an organized government weather service covering the whole country, so that synoptic weather reports could be systematically collected and charted at forecast centers. This weather service was inaugurated by the approval on Feb. 9, 1870, of a joint resolution of Congress, and service actually started on November 1 of that year under the supervision of Gen. Albert J. Myer, as a part of the Signal Service of the army.

The plan of organization was largely due to Professor Cleveland Abbe, while the administrative functions were ably conducted by General Myer. Other civilian scientists, especially Dr. Increase Allen Lapham, gave their assistance to the undertaking. Dr. Lapham had long advocated the establishment of a government weather service, and he served at the Chicago station for a short period after the new service started. He is credited with having charted the first synoptic observations of the new service followed by a forecast.

The weather service continued as a part of the United States Army Signal Service until an act of Congress made it a part of the Department of Agriculture. The name had been changed to Signal Corps in 1880. During the period to 1891, at which time the meteorological organization of the government was named the Weather Bureau, growth was gradual and largely pioneering in character, and the issue of storm warnings and forecasts for the benefit of agriculture, shipping, and commerce were the most prominent. General Myer was succeeded by Gen. William B. Hazen who was followed by Gen. A. W. Greely, noted for his polar expeditions and other scientific achievements. The first civilian to become chief of the Weather Bureau was Professor Mark W. Harrington (1891–1895), succeeded in turn by Professor Willis L. Moore (1895–1913); by Professor Charles F. Marvin (1914–1933); Dr. Willis R. Gregg (1934–1938), and lastly by the present incumbent (1947), Dr. Francis W. Reichelderfer.

Effective June 30, 1940, the Weather Bureau was transferred to the Department of Commerce in accordance with the Fourth Plan of Government Reorganization. This change was due mostly to the need for the "better coordination of Government activities relating to aviation and to commerce generally, without in any way lessening the bureau's contribution to agriculture." (H. Doc. 692 76th Congress, 3d session.)

An index of the growth of the bureau is found in the expansion of the observational network of stations. This growth was gradual but steady until about 1930, when service for aviation began to be a dominant factor, coupled with the need for a denser network, especially those for upper-air soundings, required by the application to forecasting of the polar-front theory and its accompanying use of air-mass analysis methods.

Prior to 1930 impetus was given to the bureau's growth by the satisfying in part of the need for an adequate number of stations making observations for climatological purposes. This requirement was especially recognized in the act of Congress of Oct. 1, 1890 establishing the Weather Bureau, although considerable progress had been made in that direction during the administration of General Greely, when the opening of cooperative stations was a feature. Other factors were: (1) an increase of stations reporting precipitation and stream-gage heights, required for forecasting and hydrologic studies by the River and Flood Service; (2) stations for upper-air soundings, at first (1896–1931) by means of box kites carrying meteorographs aloft, and later by airplanes accomplishing similar results (1918–1938); by pilot balloons filled with hydrogen or helium permitted to ascend freely into the upper air, and, when observed by theodolites, providing means for determining

wind velocities and directions above the earth's surface, beneath a cloud layer if present. Pilot-balloon observations started in 1918, and there has been an increasing number of stations since, and in 1944 there were 160.

A considerable number of stations were opened about 1918 for observations of evaporation, and the additional requirements made on the bureau because of World War I left lasting impressions. When radio became useful as a means of communication in 1905 it became possible to make weather observations on ships at sea and to transmit reports to land stations, and thus augment, for the benefit of forecasting especially, the synoptic reports received from land stations. This resulted in the establishment of the Marine Meteorological Service of the bureau. Radio has also provided a means of securing through exchange or otherwise observations made in foreign countries, so that northern hemisphere weather maps could be prepared.

Since 1930 the outstanding development from the observational standpoint has been the advent of the radiosonde for upper-air soundings. Experimental flights started in 1936 and 1937, followed by the initial establishment of six regularly reporting stations in 1938, steadily developing to a total of 57 land stations by 1944, supplemented by a considerable but variable number of vessel stations. The radiosonde proper is essentially a low-powered, light-weight radio transmitter. It is carried aloft by a rubber balloon filled with helium. The device has the great advantage over other means of upper-air soundings, of providing quickly and without interruption because of weather, a record of the upper-air temperature, pressure and relative humidity. Soundings are made to heights as great as 60 to 70,000 feet above sea level. Radio impulses transmitted by the radiosonde are intercepted and recorded by a short-wave radio receiver and connected ground equipment. The values of the recorded frequencies are readily interpreted in terms of the meteorological elements named.

Measurements aloft provide information by which to determine the characteristics of air masses; the stability or instability of the atmosphere; the development of thunderstorms, and areas and levels at which icing of aircraft will occur. All of these data are vital to the safety and efficiency of flying operations, as well as for weather advices to business, industry, and the general public.

Another factor involved in expanding service has been the inauguration (1939) of six-hourly synoptic observations and reports from selected land stations, the observations in 1944 being made at 1:30 and 7:30 EST, A.M. and P.M. Such reporting was required for better forecasting, especially because of the needs of aviation. Route and terminal forecasts for airplanes began as early as 1930. Many stations, both first-order and substation, are now operating on a 24-hour schedule, which is especially true of airport offices and airway and district forecast centers.

Also important has been the development of the cooperative project of the War Department (Engineers) and the bureau, which started in 1939, having flood control as its principal objective. The project has required the establishment of many hydrologic stations provided with gages for measuring and/or recording precipitation in selected watersheds.

Organization.—The Weather Bureau is an organization comprised of a network of primary or first-order stations located at or near cities in the United States and its territories, with numerous substations for observations and service operations. Their joint activities are correlated and directed by the central office at Washington, D. C., with the help and closer supervision of eight regional offices, seven of them covering the continental United States, while region 8 comprises Alaska. The names of the cities where the regional offices are located, with their respective members, are (1) New York, N.Y.; (2) Atlanta, Ga.; (3) Chicago, Ill.; (4) Fort Worth, Texas; (5) Kansas City, Mo.; (6) Los Angeles, Calif.; (7) Seattle, Wash.; (8) Anchorage, Alaska.

Stations other than regional offices are classified and defined as follows: *First-order stations* are those at which public offices are maintained and manned by full-time civil service personnel. Such offices conduct the principal activities of the bureau program, including upper-air observations, and are located at so-called city offices, or at airports; in important cities there may be offices at both locations. The airport stations necessarily center on service to aviation; those at city offices care for the broader aspects of bureau work and contact with the public. At a number of places the airport station functions in both fields of work.

Substations are those where local weather observations are taken or storm warnings displayed, or other services performed by local personnel who are not full-time civil service employees. Substations furnishing synoptic or on-call observations are designated second-order stations; all others are termed third-order stations. *Second-order stations* for example are those along airways reporting at intervals of one hour, and those off-airway stations reporting every 3 or 6 hours. Hurricane stations reporting daily or oftener to district centers are also second-order. *Third-order stations* include the following: the cooperative stations making observations of weather, temperature, and precipitation daily for climatological purposes but without compensation to the observers; also the following where local employees usually receive nominal pay for part-time services: corn and wheat, cotton-region, and sugar and rice stations reporting to Weather Bureau collection centers daily during the growing season; storm warning and hurricane display stations maintained for the dissemination of warnings for the benefit of navigation, and the coastal regions and cities which may be endangered; flood-warning stations which distribute forecasts and warnings of floods for the benefit of river navigation and the protection of life and property in areas affected by floods; fruit-frost and other stations which observe and report when needed the weather factors involved; hydrologic stations where precipitation records are maintained for hydrologic studies conducted by the Weather Bureau and cooperating agencies; river and rainfall stations which make observations of precipitation and/or river stages for transmission to district centers for use in making river-stage forecasts; snowfall stations reporting snowfall and depth of snow mainly for irrigation and water-power interests; other snowfall stations reporting for the benefit of winter sports; and fire-weather stations for transmitting reports to district centers for use in forecasts to protect forests from fire damage, and assisting in the dissemination of such warnings.

CENTRAL OFFICE ORGANIZATION AND FUNCTIONS

Broadly speaking the central office organization is divided into three parts: (1) Administrative; (2) Technical, and (3) Scientific. The chief of bureau directs, supervises, and coordinates the activities of the bureau.

Administration.—Administrative activities, under an assistant chief of bureau for administration, are divided between a division of personnel management, a budget office, and a division of administrative services. The eight regional offices of the bureau also have important administrative responsibilities. The activities of this branch of the bureau, however, are in no way peculiar to the weather service, but are similar to the same sort of functions conducted generally throughout the government. The recruitment, training, and placement of personnel; the preparation of budget estimates; allotment of appropriations and accounting for expenditures; and the procurement of services, supplies, and property are the concern of these administrative groups. Questions on organizational form and coordination of management plans are also cleared through the office of assistant chief for administration.

Technical Services Organization.—*Assistant Chief Technical Services.*—The technical field operations of the bureau are organized under an assistant chief of bureau, with the following central management and planning divisions.

Division of Station Operations.—This division administers, with the assistance of regional offices, the basic meteorological observational networks, including planning, organization, and routine observations at duly authorized stations of all kinds; prepares instructions and procedures as to observations and meteorological records; supervises operation and installment of equipment for all types of upper-air stations; initiates recommendations on staffing of stations for action of personnel division; recommends on observational networks; and, in cooperation with the division of synoptic reports and forecasts, coordinates daily weather service.

Division of Climatic and Hydrologic Services.—This division has supervision of and responsibility for checking, compiling, and publishing of meteorological and climatological data (including land-surface, marine, and upper-air) for the United States and possessions, excepting such work as is delegated to state section centers; assembly of climatic data for such services and investigations as pertain to the needs of industry, agriculture, commerce, and transportation; preparation of special reports on climates of oceans and foreign areas; determination of effects of weather on crops; and the preparation of certificates for admiralty and other litigation.

This division also directs all hydrologic work of the bureau, including specialized studies of storm precipitation and maximum possible runoff, and provides general advisory supervision for all hydrologic, hydrometeorological, and hydroclimatic work carried on at the field stations and in the regional offices, including those for river and flood forecasts and warnings, mountain snowfall and hydroclimatic substation networks, and evaporation studies.

Division of Synoptic Reports and Forecasts.—Has general supervision and administration of weather forecasting services, from transmission of basic reports to final public distribution of all types of reports, forecasts and warning by bulletins, press, telephone, radio, and other means; coordination of daily weather service in cooperation with the division of station operations; supervision of communication schedules and the maintenance of open channels for domestic, foreign and maritime communications; preparation of transmission codes; and maintenance of operating relations with communications agencies. The division also maintains the international exchanges of weather reports and information.

Instrument Division.—Has general administration of matters pertaining to meteorological equipment, including determination of requirements as to type and quantity, preparation of specifications, initiation of procurement action, testing, installations, inspections, repairs, instrumental research, building plans, exhibits, and records. The work is carried on with the aid of a corps of engineers and physicists, a laboratory equipped especially for electronics, an instrument shop, and a section devoted entirely to the radiosonde program.

Scientific Services Organization.—*Assistant Chief for Scientific Services.*—Provides advisory service in scientific and professional matters pertaining to meteorology, climatology, and statistics, including climatological and meteorological statistics and research studies for essential economic activities; supervision of authorized research projects including forecasting for the improvement of the service; general direction of approved scientific and professional training activities.

Division of Special Scientific Services.—This division is responsible for basic work in improving methods of forecasting; the preparation and verification of advisory extended forecasts for forecasters of the bureau; investigations in the physical and dynamic aspects of atmospheric problems; coordination of bureau research in forecasting and related special research projects. It also directs, plans and supervises special statistical studies of specific weather behavior.

Division of Physical Research.—A new division to engage in fundamental physical investigations, with special reference to the processes of formation and precipitation of condensed moisture, is being organized in 1947. This division will also deal with problems involving the use and application of modern electronic principles in the detection and measurement of atmospheric phenomena and their variations.

REGIONAL ORGANIZATION AND FUNCTIONS

The eight regions into which the United States and possessions are divided for the more efficient administration of the activities of the bureau, are each manned by a regional director, an executive assistant, a regional operations official, hydrologic engineer, property clerk, and a number of other assistants, all assigned to the regional office.

The regional director is the administrative representative of the central office, and his office coordinates all types of service in the region, subject to the policies and regulations of the central office. The regional office has general field supervision of all the substation activities and networks in the region excepting those delegated to certain first-order stations for more efficient handling, and the operations officer is required to assist the regional director in coordinating all station inspections. He also supervises the inspec-

tion staffs and personally inspects first-order stations in collaboration with district forecasters when required. The hydrologic service is administered by regional directors with the active assistance of the hydrologic engineers. Regional fiscal, personnel and property transactions are also handled by a specialized administrative staff in the regional offices.

District Forecast Centers.—Each of the twelve centers in continental United States (also one in Alaska) is primarily responsible for all forecasts for its district and for their distribution. Each center also operates as a first-order station and is subject to the general administration of the regional office having jurisdiction.

Washington National Airport Station is an example of the organization required for district and airway forecasting, and for taking surface and upper-air observations required in whole or in part of all synoptic-reporting stations. In addition a flight watch is maintained especially for the benefit of aviation. A meteorologist is responsible as official in charge for the general administration of the station. Continuous service is necessary, and forecast charts are prepared at least four times during each 24 hours to utilize the many observations received mostly by teletype and a few by telegraph. There are many hourly observations received also by teletype from stations along the several airways centering at Washington.

Weather forecasting and general services require four groups of forecasters under a leading forecaster: one group of four for district forecasts, covering the states of New York, Pennsylvania. New Jersey, Delaware, Maryland, Virginia, West Virginia, Kentucky, and Tennessee; another of five for airway forecasts; five for the flight watch, and nine for trans-Atlantic flight forecasting and pilot briefing.

The preparation of maps and charts requires the services of twenty-four men and women. Weather observing services require nine observers, three for the twice-daily radiosonde ascensions and six for surface and pilot-balloon observations. Another activity requiring considerable personnel cares for the analysis and verification of records and forms received from Weather Bureau radiosonde stations in the field.

Climatological Section Centers.—These are first-order stations where the climatological work of a state or a group of states is carried on. There are 43 of them: one for New England, one for Maryland and Delaware, and one for each of the other states and for Alaska, the Hawaiian Islands, and Puerto Rico, including the West Indies. Each section center selects and instructs the cooperative observers and the weather-crop correspondents, and prepares climatological publications and reports for the section. Inspections of such stations are regularly a function of the regional office where substation inspections of all kinds are centered, but joint inspections with section center personnel are made when necessary.

Under a new item of appropriations for fiscal year 1948, it is expected that the processing of climatological records will be done by modern machine-card methods.

River District Centers; River and Flood Service.—Such centers are responsible for and have the direct management of the substation network in their respective districts, from which daily reports of river stages and precipitation are received and form the basis for the flood warnings and forecasts issued from the district center.

The appropriate regional office coordinates all flood reports and clears all recommendations relative to substation changes. Regional office hydrologic engineers, acting under the general supervision of the hydrologic director in the central office, assist the river district centers in matters concerning changes and developments of river and flood forecasting procedures, and assist in flood emergencies.

SERVICES

The public requires weather information and service along three principal lines which are interdependent and closely related: (1) the forecasting of the weather, usually rated as the most important; (2) the reporting of current or very recent weather conditions and elements, such as are found on weather maps and bulletins, or which are made public by telephone or radio; and (3) the records of past weather, as given by averages or normals of the meteorological elements, or the departures therefrom, such as are published in climatological and monthly meterological summaries, in the *Weekly Weather and Crop Bulletin,* the *United States Meteorological Yearbook,* the *Monthly Weather Review* and others; all of which include interesting comparisons of current weather with the normals. It has been estimated that services required and rendered by the Weather Bureau increased by 200 per cent from 1935 to 1944.

The observation-station networks provide basic data in all three of the above categories; hence the far-reaching importance of accurate instruments and of accurate reading and reporting, toward which competence the in-service training of new observer employees is directed. Speed and timing are also important, especially where forecasting is the main objective, in order that forecasts may reach waiting users quickly for prompt application to operations in commerce, agriculture, aviation, and many other activities.

The many synoptic reports, both surface and upper-air, are promptly charted and analyzed at forecast centers, and soon the forecasts are in evidence on the radio, in the newspapers, on the automatic telephone, and often by telegraph messages sent direct to important users.

Operating Functions of the Weather Bureau.—These are shown in picture form in Fig. 1, the sources of weather reports appearing on the left hand, the operations of forecast and other centers, where the material is charted, analyzed, or processed for use, are shown in the center, followed on the right by the several ways and means of effectually reaching the public. The systematic and efficient handling by teletype, telegraph, and radio of all of these reports through the several "collection centers and selective distribution headquarters," is in itself a work of major importance, involving the use of number codes and the most intensive planning and execution. This work is administered by the division of synoptic reports and forecasts of the central office with the cooperating field stations. Full use is made of the teletype and other communication facilities provided by the Civil Aeronautics Administration.

General Weather Service.—This is the service best known to the public, which provides the current weather reports and frequent forecasts, usually for short periods of time. State fore-

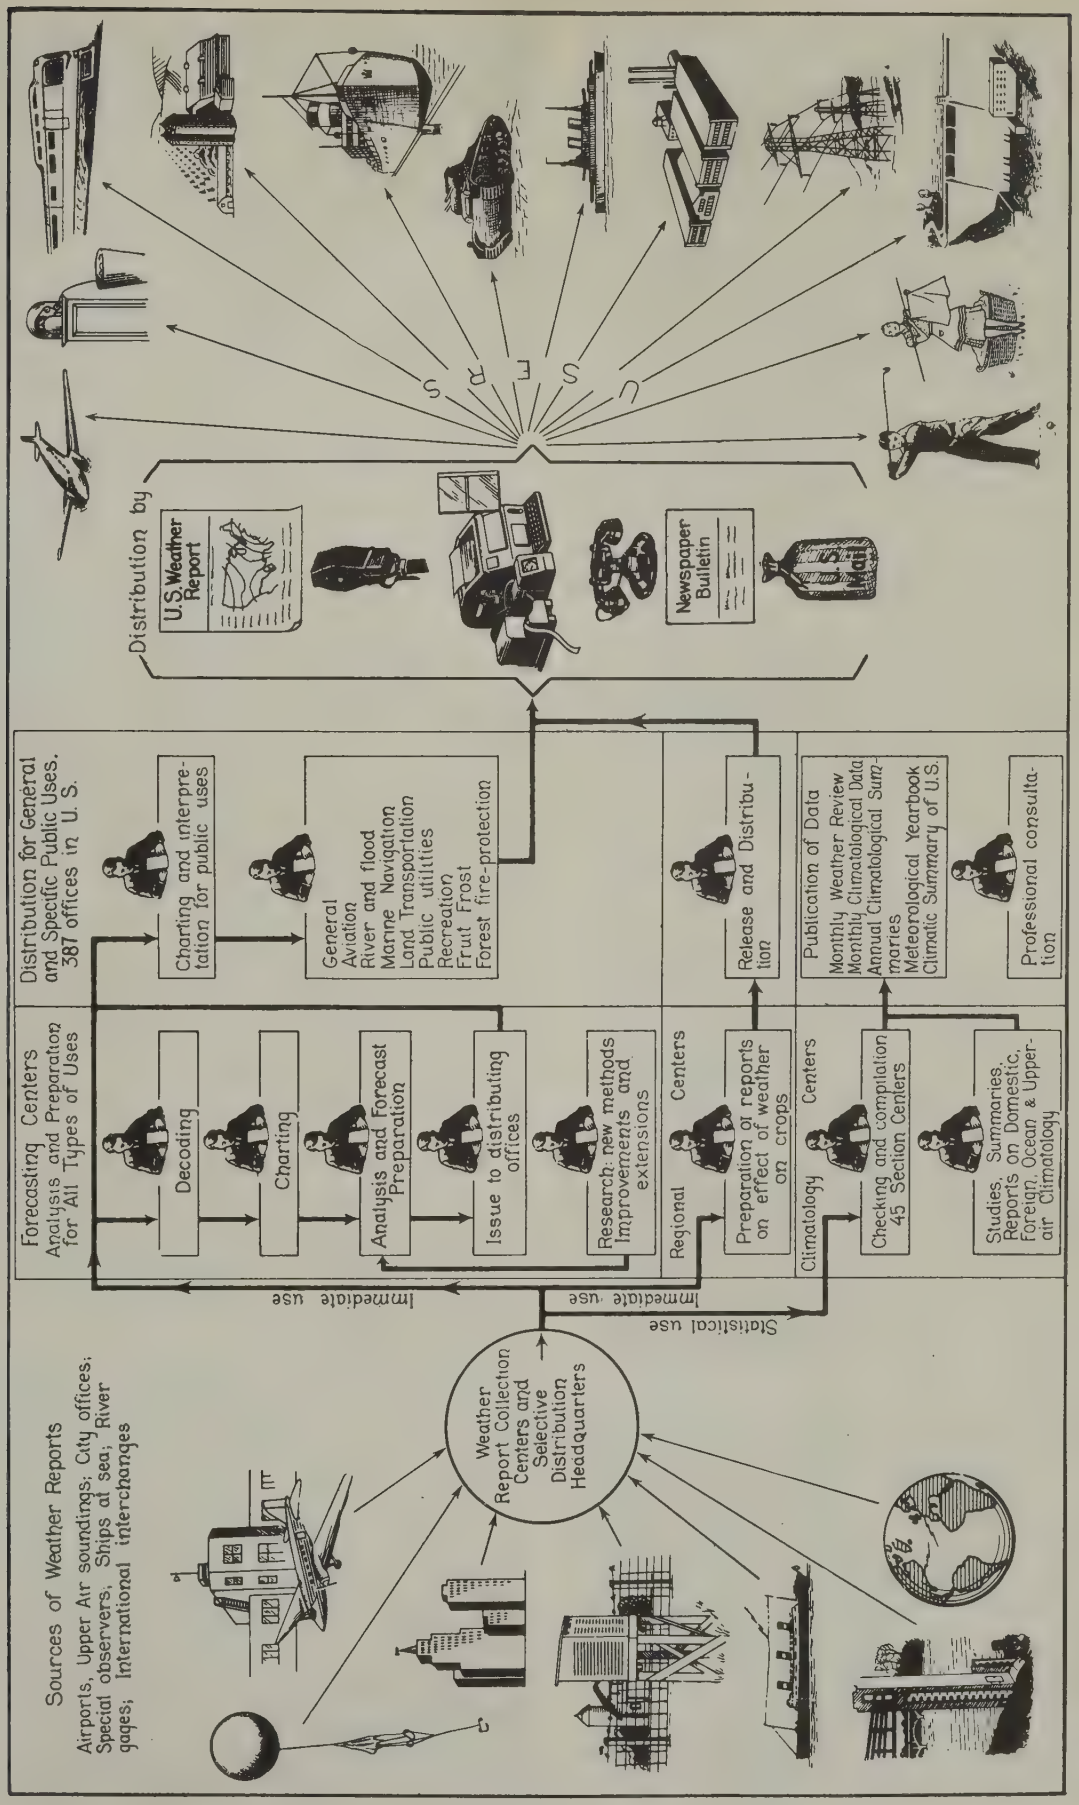

FIG. 1. How the Weather Bureau works.

casts are issued by the district forecast centers, and local forecasts by the several Weather Bureau offices authorized to prepare and issue the same. The local forecasts are modifications of the state forecasts which take into account the peculiarities of weather in and near the cities where the local forecasts originate. Distribution is made effective mostly through the radio and the newspapers, especially the former which reaches far and wide, even to vessels at sea. The distribution of printed bulletins and maps by the Weather Bureau, usually by mail, is also important, although not so expeditious as radio and telephone. The teletype linking airway and airport stations with drops to nearby city offices of the bureau, is also a valuable and practically indispensable factor in the communications system, both for the collection of reports and the means for ready access to many Weather Bureau offices and others, thereby bringing them the forecasts, warnings, and other important information direct for quick redistribution, or such usage as is necessary. Much information reaches the public through personal telephone inquiries made to Weather Bureau offices, and in times of emergencies such service reaches large proportions.

Summarizing, district forecast centers issue state, coastal, marine, and general forecasts; also warnings of storm, whole gale, hurricane, cold waves, blizzards, frost and freezing temperatures, glaze or freezing rain, heavy rains and other special warnings and services for areas and particular interests within their respective districts, such as those for fire-weather, fruit spray, or winter sports. There is also a service for reporting severe local storms such as tornadoes, thunderstorms, hail storms, and the high winds usually experienced under such conditions. Reports are gathered at collecting centers, and forecasts and warnings issued when possible of individual local storms or groups of storms. The direction of movement and future intensity of such storms can be estimated with a considerable degree of accuracy for several hours in advance and warnings can be issued which will protect life and property. This service is in effect in the Gulf states, and the interior valleys and Great Plains states.

Aviation Weather Service.—This important and growing service was authorized by the Air Commerce Act of 1926 and given its present form by the Civil Aeronautics Act of 1938. These acts place the responsibility upon the Weather Bureau of providing an adequate meteorological service for the benefit of aviation and thus "to promote the safety and efficiency of air navigation in the United States and above the high seas."

The needs of this service require the taking of land-surface and upper-air observations, every hour at least for the former at stations along the airways, and at intervals of three to six hours at off-airway stations. On-call stations make reports when requested. The upper-air pilot-balloon stations report every six hours, and the radiosonde stations twice daily as a rule. There are nearly 600 airway substations, mostly on the airways, and the airway observation network includes the Weather Bureau first-order stations which add regular land-surface observations in addition to the upper-air.

Reports are assembled promptly at airway forecasting centers and airway terminals. Forecasts are made currently available for aircraft in flight and the observational data also to others needing complete information. Such data are also summarized in a form suitable for analysis and publication; all in all the service is organized and operates especially as a direct aid to air navigation.

Forecasts are issued for all civil airways, specified regions, and individual terminals for a period usually not exceeding 12 hours. Airway forecasters also make use of the state forecasts issued by the district forecast centers. Trip or route forecasts which are based upon the general forecasts but which are supplemented by any more recent reports from points en route are issued for individual flights upon request. Service is also made available upon request to off-airway airports.

Flight Advisory Weather Service.—This new service was organized and established in the latter part of 1943 at Civil Aeronautics Administration traffic control centers. It provides current weather information, and similar prospective information for the immediate future, for transmission to pilots in flight or for control of air traffic. The object is to provide a greater degree of safety in flight, the information being based on weather trends or short-period forecasts, and current weather reports, both from land stations and conditions aloft as reported by airplanes in flight or determined by upper-air observations with pilot-balloon and radiosondes.

The service is made fully efficient and dependable by the active and close collaboration of Weather Bureau forecasters, observers, and other station personnel, with officials and employees of the airway traffic control and airway communications stations.

Hurricane and Storm-warning Service.—Hurricane warnings, advisories, and preliminary hurricane alerts are issued from the forecast centers at Miami, New Orleans, San Juan (Puerto Rico), Washington, Boston, Los Angeles, and San Francisco. Alerts are ordered to cover a period of uncertainty during which winds of hurricane force may endanger a locality or area within 24 to 36 hours when conditions do not as yet warrant a definite warning.

When a hurricane or other tropical disturbance, developing or in progress, is at such a distance as not to warrant the issue of an alert or a hurricane warning for any land area, an advisory warning, if required, will be issued. This is done so that communities in the probable path of the storm may be placed on guard well in advance of the storm and be kept informed as to its movement and development.

Storm and small craft warnings are issued for the aid of marine shipping and other interests on the Great Lakes and the seacoasts of the United States and its possessions, and, when required, for vessels plying the sea lanes leading thereto. Hurricane warnings are usually confined to the Gulf and South Atlantic coasts, but sometimes are required for the Middle and North Atlantic coasts and the South Pacific coast as well.

Distribution of warnings is made in the usual way on the Great Lakes and most of the seacoasts, but during the hurricane season, June to October, inclusive, use is made of a special teletype system along the Gulf and South Atlantic coasts, reaching inland also to such cities as Atlanta, New Orleans, Houston, and San Antonio. This teletype aids greatly in quickly reaching the connected Weather Bureau stations and other in-

terests when these usually destructive storms are imminent. It serves also in disseminating the very essential reports received from the special hurricane observing stations and from vessels located in the West Indies and contiguous areas where these storms often have their origin. Such observations, particularly needed by forecast centers, are received by radio and wire at collection centers and placed on the teletype, so that they are quickly available at forecast offices.

Storm and hurricane warnings also reach the public by display of flags and electric lanterns, mostly where steel towers have been erected by the bureau especially for the purpose. There are nearly 500 of such special display stations, located as a rule where passing vessels can readily see the flags and lanterns.

River and Flood Forecasting Service.—This important service is maintained in the public interest for the primary purpose of preparing and issuing forecasts and warnings of damaging floods, and of providing forecasts and other information for those interests concerned in the normal or low-river stages. Most of the navigable rivers are covered by this service.

The continental United States is divided at this time (1947) into 86 river districts each with its forecast center, and there are nearly 2,500 substations reporting rainfall and/or river stages, snowfall, and evaporation. Specialized river forecast centers are maintained at Cincinnati (for the Ohio Basin), and at Kansas City (for the Missouri Basin). These centers prepare general river and flood forecasts, using the most modern hydrologic techniques, which are communicated to the local river district centers for their guidance and detailed application to their respective areas of responsibility. Several more such centers are contemplated.

Forecasts are based upon the observational data coupled with a thorough knowledge of watershed runoff and other factors governing the expected water stages and the time of the occurrence. Such forecasts have a high degree of accuracy, and the protection and savings of life and property resulting from their use is very large.

Services of this activity include also the determination of available water supply for irrigation, hydroelectric power-plant usage, etc. resulting from the melting of snow in the spring and early summer which has accumulated in natural storage in the mountain regions of the west.

Hydrometeorological Service.—Specialized services for flood control and reclamation engineering are maintained. Techniques are developed for estimating the maximum possible precipitation and available runoff from certain watersheds under investigation to determine the meteorological factors bearing upon flood-control and reclamation projects. Such investigations require dense networks of precipitation-measuring stations, using both recording and non-recording gages. The results of such studies will be found ultimately in the comparative freedom from damaging floods of watersheds where flood-control measures and works are introduced and built under the direction of the War Department engineers.

Climatological and Crop-Weather Services.—The main objective of these services may be summarized as follows: To determine the climatic characteristics of the United States and its possessions, requiring the publication of climatic data in such form as to be readily understood by the public; to make necessary studies of the climates of foreign lands; to supervise the collection and publication of reports showing the effect of weather on crops; and in general to analyze statistically the observational data involved.

Land-surface observations are made mostly by the many so-called cooperative observers serving without pay, of which there are now (1947) more than 5,600. These are supplemented by numerous observations from other land stations, for example the airway stations, and all first-order stations make observations for climatological purposes, often both surface and upper-air. The continued processing of such data over long periods of time results in the determination of the normals, extremes, departures from normals, of the several meteorological elements, which when combined constitute the climatology of a city, a state, or a region. Climatology, briefly, is based upon regular, daily observations of weather, temperature, wind, precipitation, and other elements from a widespread network of stations.

A featured service of long standing is the issue of weekly bulletins showing the relation of crop production to current weather. The principal publication, called the *Weekly Weather and Crop Bulletin,* is issued from the central office at Washington, D. C. It contains a summary of weather conditions for the past week for the entire United States, accompanied by statistics giving the precipitation and mean temperature for the week and their departures from normal. This material is supplemented by a general summary of crop conditions and work as affected by the current weather followed by individual reports from the various states.

Other similar bulletins are issued by field stations; one from New Orleans covering the valuable cotton crop, and also sugar and rice; and other bulletins are issued by state section centers in regions where corn and wheat production is of major importance.

The tabulation and analysis of climatological records by modern machine-card processes is being instituted. New climatological facts, of great importance to the national economy, but hitherto not available by hand methods of analysis and computation, will be readily available by use of this new and modern technique of processing the voluminous records from many years of observations.

Marine Meteorological Service.—The purpose of this important service is to obtain surface and upper-air weather reports from vessels at sea, preferably synoptic reports to supplement those obtained from land stations. In turn the Weather Bureau furnishes vessels at sea as needed with forecasts, storm and hurricane warnings, and other useful information. The service fosters improvement in the accuracy standards both of the instruments employed and the observing technique, especially as regards the barometers, the readings of which are used in charting pressure areas and locating storms. The meteorological reports of whatever kind are all valuable in the compilation of ocean weather summaries and for studies of marine climate, storms at sea, and weather conditions affecting transoceanic aviation.

Every effort is made to encourage the cooperation of vessels at sea, especially those of American registry, in furnishing reports, and also

to transmitting these reports by radio to foreign meteorological services. Under normal conditions broadcasts by radio of "major weather bulletins" are made over the several naval radio stations, so that vessels at sea may receive sufficient reports to prepare weather maps, thus contributing to the safety of life and property at sea. Such broadcasts also describe fully the weather prevailing between southern North America and northern South America and from the Bahamas to the mid-Pacific.

The accumulated observational data has been used during the past several years especially in improving the pilot charts issued by the Hydrographic Office of the United States Navy. These charts provide special wind data, fog and gale frequencies, and average wind and weather conditions at sea.

The radio-reporting service for the North Atlantic is supervised by the Weather Bureau Office at New York City, that for the Gulf of Mexico and the Caribbean by New Orleans, the Pacific Ocean by San Francisco, and the Great Lakes by Cleveland. The work is further divided among the rather numerous port stations where bureau offices are located. Such stations collect marine weather reports, make personal contacts with ships' officers and shipping companies, keep the observers furnished with supplies and forms and make careful inspections and comparisons with standards of the meteorological instruments aboard ship.

Special Forecast and Warning Services.—District forecast centers assisted by local Weather Bureau offices prepare and issue special forecasts and warnings affecting public utilities, important industrial organizations, manufacturing establishments, military and naval authorities, hydroelectric flood control projects, and construction jobs. Other special forecasts enable the farmer to plan his harvesting, the spraying of fruit and vegetables and other operations. Livestock and poultry interests also receive warning of conditions affecting them, such as blizzards, cold waves, heavy snows, low temperatures, floods, or cold rains with strong winds.

Highway Forecasts.—Close cooperation exists between the bureau and state highway patrols and maintenance departments and current weather information is made available promptly to the public in the interest of safety. Warnings of heavy snows, cold waves, freezing rain, floods, and such factors as endanger motor traffic and other interests, are of particular value. Such forecasts are often confined to local areas of 100 miles or so radius about the issuing station.

Winter Sports.—Places where winter sports are important receive special forecasts during the winter season each Thursday or Friday or oftener. Special bulletins are issued by local Weather Bureau offices and given distribution by press, radio, mail, and other means.

Special Forecasts and Warnings for Horticulture.—Under this heading the special forecasts and warnings issued by the fruit-frost forecast centers stand foremost. Knowledge of expected minimum temperatures and accompanying weather conditions enables the orchardists and others to protect fruit crops from damage usually by heating the orchards above the critical minimum. Forecasts are based on the general synoptic weather conditions coupled with current reports, especially of temperature, received from numerous stations located in or near the areas affected. Such service is particularly valuable in the protection of the citrus fruits and winter vegetables of California, Florida, and the lower Rio Grande Valley. It has been in operation in California since 1913. Other fruits are also protected from frost damage by suitable means, not only deciduous tree fruits but small fruits such as strawberries or cranberries. Shippers receive separate temperature forecasts which enable them to counteract expected low or high temperatures, especially the former, to be experienced by perishable products in shipment en route.

Fire-Weather Forecast and Warning Service.—This important service involves forecasting in its relation to the protection of our valuable forests from fires which are started by lightning or accidentally, when weather and other conditions are favorable. Protection is made possible through an accurate knowledge of current weather, relative humidity, moisture, temperature, wind direction and velocity, and visibility, taken together with forecasts of changes affecting the degree of hazard from fire. Forecasts of wind, precipitation, and thunderstorms accompanied by lightning from cloud to earth, are especially valuable, as they affect the starting, progress, and control of forest fires. The Forest Service of the Department of Agriculture and the Weather Bureau have long collaborated in this important work of protecting and conserving our forests. Other cooperating agencies render valuable assistance such as the National Park Service, the Indian Service, the Grazing Service, together with state, county and private forest protection agencies.

WEATHERFORD, wĕth'ĕr-fĕrd, **William,** (known also as Red Eagle), American Creek Indian chief: b. Creek Settlement, Ala., about 1780; d. Monroe County, Ala., Mar. 9, 1824. At the outbreak of the Creek War he led the attack on Fort Mims, Aug. 30, 1813, and the massacre of some 500 victims—men, women, and children. Also he was one of the leaders of the Creek Indians at Horseshoe Bend, Jan. 27, 1814, and was defeated by Andrew Jackson, after which he surrendered. He lived at peace thereafter on a plantation among the white people of Monroe County.

WEATHERFORD, city, Oklahoma, in Custer County, altitude 1,644 feet, served by the Chicago, Rock Island and Pacific Railroad, is situated 14 miles east of Clinton. It is the trade center of a wheat and cotton area; its industries are: cotton ginning, and the manufacture of wood products. Weatherford is the seat of the Southwestern Institute of Technology; nearby is an Indian hospital. The city was founded in 1893. Pop. (1950) 3,529.

WEATHERFORD, city, Texas, seat of Parker County, altitude 864 feet, is served by the Texas and Pacific; and the Gulf, Colorado and Santa Fe railroads. It is located 27 miles west of Fort Worth, and is the trading center for a rich agricultural region, and the market center for its products: melons, cotton, grains, pecans, peanuts, and cattle. The local industries

are: cottonseed and peanut oil milling, pecan shelling, and grain milling; the manufactures are: oil-field equipment and clothing. There are limestone and clay deposits in the locality. The city has a junior college (state; coeducational), a Carnegie library, a high school and a hospital. First settled in 1850, and incorporated in 1856, the city's charter dates from 1858. Its water, electric lighting, and gas systems are city owned and operated. Government is by a mayor and council. Pop. (1940) 5,924; (1950) 8,093.

WEATHERING, wĕth'ĕr-ĭng, a geological term which describes the gradual action of the atmosphere upon rock material. See also GEOLOGY—*Petrography and Petrology;* METAMORPHIC ROCKS.

The term is also used in architecture to describe outward sloping at cornices, window sills, etc., to throw off rain.

WEATHERLY, wĕth'ĕr-lĭ, **Frederic Edward,** English lawyer, and writer of popular songs: b. Portshead, Somerset, Eng., Oct. 4, 1848; d. Bathwick, England, Sept. 7, 1929. He was graduated from Oxford University in 1871, and called to the bar of the Inner Temple, London, in 1887. Among his many popular songs are: *Nancy Lee, Darby and Joan, London Bridge, Danny Boy,* and *Roses of Picardy.* He was also the author of various books of verse and other volumes of academic interest.

WEAVER, wē'vĕr, **Aaron Ward,** American naval officer: b. District of Columbia, July 1, 1832; d. Oct. 2, 1919. He was graduated from the United States Naval Academy in 1854, and became lieutenant in 1855. In 1858–1859 he cruised along the African coast in the sloop *Marion,* and returned in command of the prize slaver *Ardennes.* Having served in the Union Army with distinction through the Civil War, he was made commander in 1866, captain in 1876, and rear admiral in 1893, in September of which year he retired.

WEAVER, Emily Poynton, Canadian author: b. near Manchester, Eng., in 1865; d. Toronto, Ont., Can., March 11, 1943. She removed with her parents to Canada in 1880, and subsequently lived in Oxford County, Ontario, and in Halifax, Nova Scotia, and Toronto. She became known as a writer of short fiction, historical essays for magazines, and author of several books, among them *My Lady Nell* (1889); *The Rainproof Invention* (1896); *Builders of the Dominion* (1907); *The Trouble Man* (1911); *Canada and the British Immigrant* (1914); and *The Book of Canada* (1928).

WEAVER, James Baird, American lawyer and politician: b. Dayton, Ohio, June 12, 1833; d. Des Moines, Iowa, Feb. 6, 1912. He was graduated from Ohio University Law School, 1854, and began practice at Bloomfield, Iowa. In 1861 he entered the Union Army, was promoted colonel in 1862, and brevetted brigadier general in March 1864. In 1866–1870 he was district attorney, second judicial district of Iowa, and in 1867–1873 assessor of internal revenue first Iowa district. For some time he was editor of the Iowa *Tribune,* published at Des Moines. He took an active part in the organization of the Greenback Party and was elected to Congress on its ticket in 1879, serving one term. In 1880 he was the Greenback candidate for president, receiving over 300,000 popular votes. Later he was affiliated with the People's Party and was a delegate to the National Convention in 1892 and again nominated for the presidency when he won 22 electoral votes and a popular vote of 1,041,021. After 1895 he lived in Colfax, Iowa, and was mayor of that city from 1903–1906. He wrote *A Call to Action* (1892), and *Past and Present of Jasper County, Iowa* (1912).

WEAVER, Jonathan, American clergyman, bishop of the United Brethren in Christ: b. Carroll County, Ohio, Feb. 23, 1824; d. Dayton, Ohio, Feb. 6, 1901. Educated in the common schools and the Hagerston Academy, Ohio, he began to preach in 1845 but did not join a conference until 1847. After serving several appointments he became presiding elder in 1852 and was agent for Otterbein University, Westerville, Ohio, from 1857 to 1865 when he was elected bishop. In 1893 he became bishop emeritus. He was one of the greatest leaders of his church and was the author of a number of books on theological subjects.

WEAVERBIRD or **WEAVER,** a bird of the Ploceidae family remarkable for their nests many of which are marvelously woven. The family ranges almost throughout the Old World and includes the Old World sparrows (e.g., the house sparrow, *Passer domesticus*). The weavers themselves number well over 200 species. They range the tropics and southward to South Africa and Tasmania and include the Java sparrow (*Padda oryzivora*) and the Australian finches. They run from 3 to 10 inches in length, besides long-tailed kinds up to 20 inches, and closely resemble true finches (Fringillidae), having the finch types of bill, moderate wings with the outer primary quill better developed, short to very long tail and even more varied coloring often with great differences due to sex, age and—less often—season.

Weavers are extremely social and many breed in colonies. All nests are domed, the entrance—often tubular—at the side or bottom. There is no more beautifully woven nest than that of the bayas (*Ploceus*) of tropic Asia (but not the Philippines) of grass and strips of palm leaf, retort-shaped with an entrance tube of some inches, even up to three feet, at the bottom and hung by a short rope of the same material from the tip of a tree branch, often over water, sometimes from a building, and usually secure from climbing enemies. Both sexes work on it, and when finished the male commonly builds others, for which he may get other mates, and an unfinished one, a dome over a woven perch, serves as a sheltered roost for himself. Some weavers nest in bushes, some in tall grass; some use twigs, sometimes thorny ones, and the white-headed weaver (*Dinemellia dinemelli*) strews the branches of its nest-tree with thorny twigs which may deter small climbers. The nests of one species of weaverbird, the sociable grosbeak (*Philhetaerus socius*), of Africa, composed solely of grass, are built cooperatively. They are joined together in aggregated masses, sometimes as many as 100 to 200, or more, and all are entered from the bottom of the mass. They have the appearance of a huge mushroom, at a distance sometimes mistaken for a native hut.

The black and yellow weaver (*Textor cucullatus*) nests in conspicuous colonies in trees usu-

ally among houses, and has been introduced and established in Hispaniola as have two other smaller African species in Puerto Rico. Well-known groups are the tiny waxbills and mannikins, the black and flame-colored (yellow to red) bishops and the long-tailed widowbirds or whydahs. Females, young and winter males of bishops and whydahs are sparrow-like.

Consult Bartlett, *Monograph of the Weaverbirds* (Maidstone 1888).

WEAVERS, The. The misery of the Silesian weavers of the second quarter of the 19th century, which inspired Heine to a moving ballad, is the theme of Gerhart Hauptmann's best known play. Hauptmann derived his intimate feeling for it chiefly from the lips of his grandfather, one of the actual sufferers; and in his work *Die Weber* (*The Weavers* 1892) he has given to industrial revolution a stronger sanction than can be found in any other dramatic work whatever. *Die Weber* is rather a series of five one-act dramas than a drama in five acts. Different groups of persons appear in five different places. But the persons belong to the same community, they pass to and fro, and the five acts, each a unit with skilful exposition and a theatrical conclusion, constitute a greater whole, in which rebellion is carried to temporary success, but which is mainly impressive for the presentation of conditions that cry out for a remedy. There is no hero; every person is an integral character, every one a reality, and to the tragedy of starvation as the only reward for toil is added the pathos of vicarious atonement: an old weaver who refuses to leave his loom in order to join his fellows in rebellion is shot by a stray bullet. Hauptmann's method is unqualifiedly naturalistic. The play was first written in the harsh Silesian dialect, and the revised form in general circulation is only approximated to the literary language. It smacks of the soil. Its power resides in its apparent artlessness, in the impressiveness of truth naked and unadorned. There is, however, in a treatment of squalor which arouses unmixed sympathy a high degree of art, as there is also a preachment the more eloquent for being left to be inferred. Its text is the simple precept, give them their daily bread.

WILLIAM G. HOWARD.

WEAVING, Hand Loomed. Weaving is the crosswise interlacing of at least two sets of parallel fibers or threads of any kind. These may be the whole leaves, bark or other parts of natural plants; the prepared plant fibers such as cotton thread or paper; animal fibers such as silk or wool, or leather strips; wire or flat strips made from metals such as gold or silver; spun yarns from minerals such as asbestos or glass; or various man-made, chemically prepared fibers such as rayon and nylon. The purpose of weaving is to lock the separate fibers or strands into a connected, orderly expanse or web of desired size.

The first set of threads, which extended lengthwise in front of the weaver provides the foundation for the cloth, is called the warp. The cut ends of warp threads are called warp ends. The second set, interlaced in an alternate under and over sequence to fill the spaces across the width of the warp, is called the weft or woof. The sequence and spacing in which the two sets of fibers are interlaced determines the kind of weave which will be produced.

The interlacing may be done entirely by hand without the use of any frame or mechanical device, particularly if reeds, grasses, leaves or other relatively stiff, short fibers are to be woven as in the case of some types of grass mats. This is achieved by laying the warp in parallel rows on the ground or on lap boards, such as those used in the Marshall Islands, and guiding the weft fibers alternately over and under the warp strands, thus locking the two groups together.

The method is not, however, practical for weaving long lengths of cloth and hand loom weaving is, therefore, done on a frame to which the warp threads are attached and held at a suitable tension to keep them in an even, parallel position. In this way the weft may more easily and quickly be guided into place either with the fingers alone or with the aid of a shuttle. The shuttle, which may be merely a twig or thin stick, holds the supply of weft thread. Each passage of the weft across the alternate warp threads is called a shot or pick, the work generally, but not always, starting at the end nearest the weaver and progressing toward the distant end of the warp.

Shuttles.—The implement around which the weft supply is wound and passed across the warp to form a web is called a shuttle. It is designed in many variations which may be divided into two main categories—those from which the weft must be unwound by hand and those constructed with a revolving bobbin or quill to unwind automatically when being used. They are chosen according to the preference and convenience of the weaver. In some cases shuttles are not used at all, the weft simply being used in short, stiff lengths or wound into a ball that can be passed between the warp layers when needed.

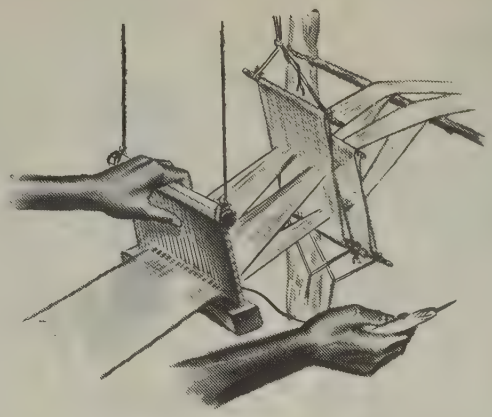
Weaver's Comb or Reed.—The woven rows of stiff grasses and reeds, when a special implement is lacking, can be pressed together compactly by the pressure of the weaver's fingers, but when soft, flexible fibers in the form of cord or yarn are used a better, less tiring method is necessary. The need was at first filled by a notched or forked twig or a piece of bone, which later was developed into a short handled comb known as a weaver's comb. Still later the need for an improvement was filled by the reed or sley, a device that was developed for another purpose and which was actually made of reeds that grew near the weaver's dwelling. Thus used it represents the third of the earliest major loom improvements in hand loom weaving.

Looms.—Most hand looms are equipped with rollers at the back and front of the frame, for storing the supply of warp to be woven and for the finished cloth. They have, in addition, a simple automatic method of raising or lowering the alternating groups of warp threads as they are needed, in conjunction with which they are also equipped with either hand or foot levers.

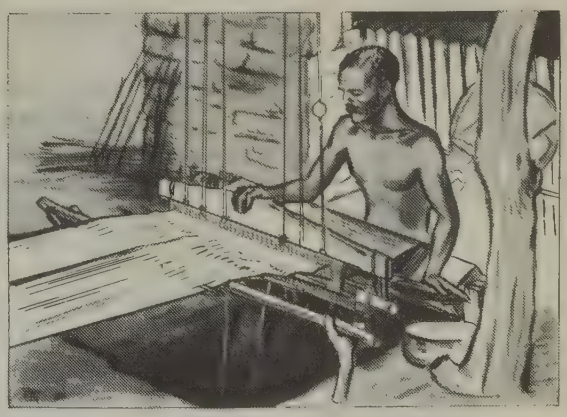
The frames used for all types of weaving are called looms.

The most intricate forms of weaving can be, and sometimes are, done on the simplest of looms, but the work, especially where complex patterns are desired, is arduous and exceedingly slow; therefore, over many centuries ingenious minds have devised many loom improvements to accelerate and lighten the task. These improved looms, while adding immeasurably to the speed at which the weaving may progress, have in no way changed the fundamental principle of interlacing the fibers or threads.

WEAVING, HAND LOOM

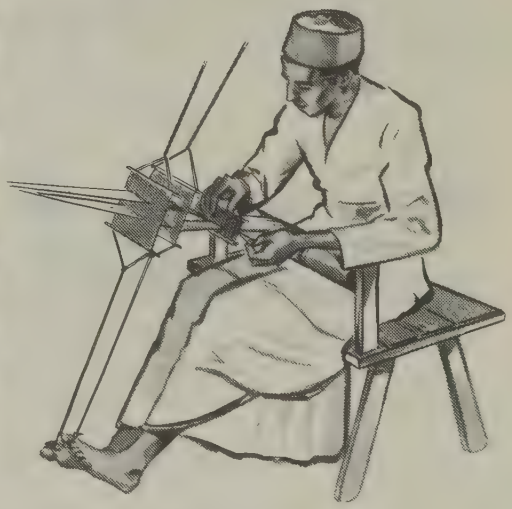


Details of an Eastern loom.

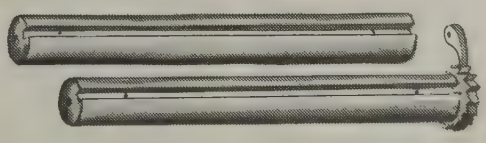


A simple pit loom of the Far East.

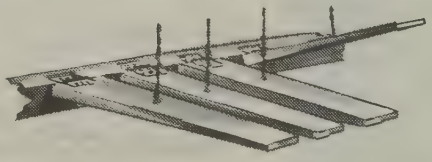
A Montaña Indian weaver of Peru. The long fabric lengths are started from both ends on these backstrap looms. The last few center rows are woven in with a needle.



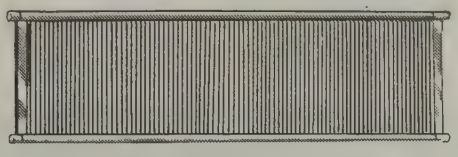
One method of weaving in Hyderabad, or Haidarabad.



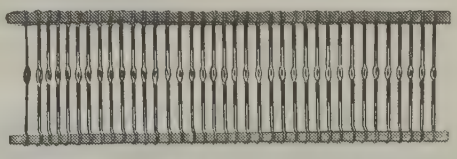
Warp and cloth rollers with locking device.



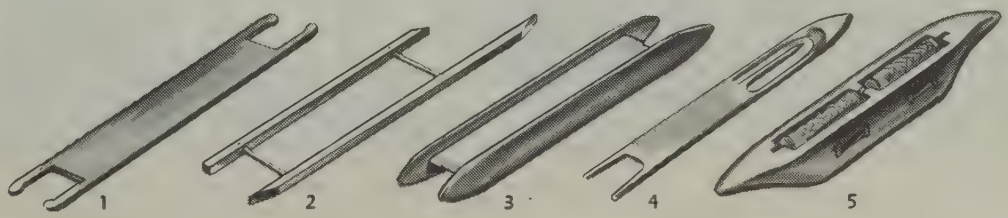
Treadle action of a floor loom.



Modern metal reed.

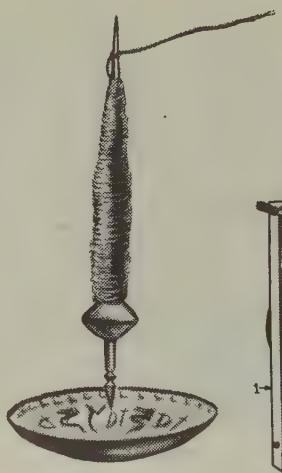


Heddles, headles or healds, mounted on bars.

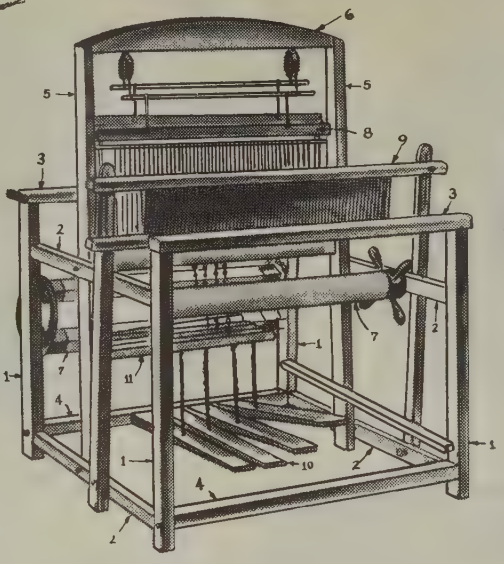


(1) Flat shuttle. (2-3) Rag or rug shuttles. (4) Pick-up shuttle. (5) Boat or throw shuttle.

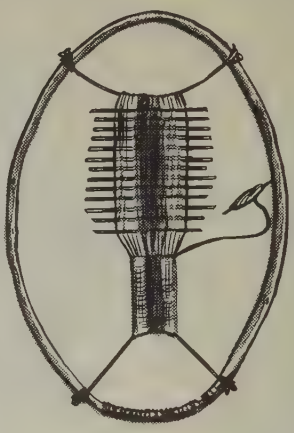
WEAVING, HAND LOOM



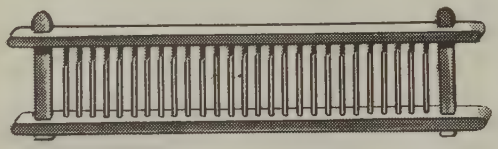
A Montana Indian spindle, with earthen dish. Others vary from delicate seven- or eight-inch Eastern types to the huge four-foot style of certain northwestern Salish tribes.



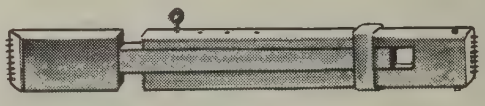
A modern floor loom, developed over many centuries. Numbered parts are identified in the text. In principle, all looms are the same.



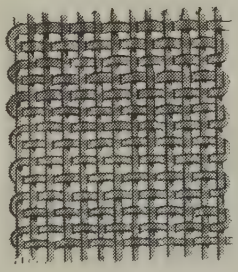
An O or oval loom, of the Pancan and Arawak tribes of Peru. Thin reeds are inserted to set the sheds before weaving begins. Two cords fastened to the frame hold the warp securely in place.



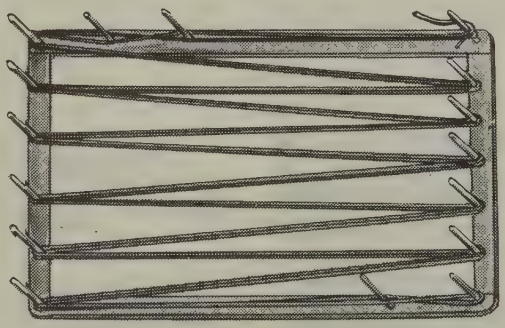
A raddle, used to spread the warp evenly while it is being wound on the warp roller or beam, is similar to a very coarse reed in appearance. It is temporarily secured to the upper back or front beam and removed when the warp is wound.



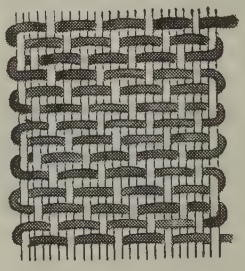
A temple or tenterhook for keeping the width of the finished cloth stretched evenly before being rolled on cloth roller. The pronged ends of the temple are set into the selvedges of the cloth, being moved when necessary as weaving progresses.



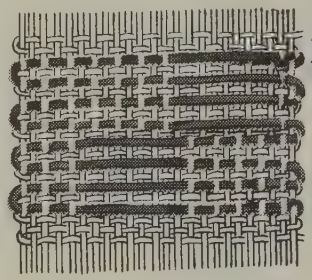
Tabby or plain cloth. The most widely used of the three major fabrics.



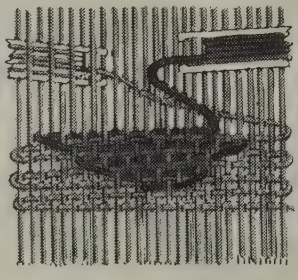
A pegged warping frame for measuring the length of the warp and keeping threads in order.



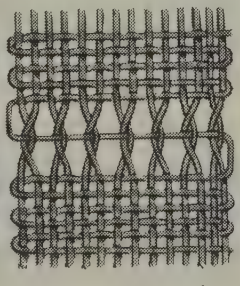
Twill, recognized by its diagonal weft lines, is second major weave.



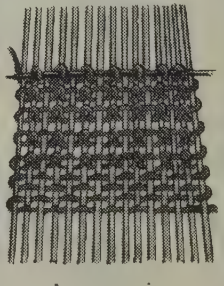
Overshot weaving



Laid-in weaving



Leno or gauze weaving



Loop weaving

The horizontal type of loom with which we are most familiar is of an open boxlike construction which is made of: (1) corner capes or posts; (2) upper and lower side beams; (3) upper front and back beams, known respectively as breast beam and whip beam or slabstock; (4) lower front and back stretcher beams; (5) vertical side beams at the center of the frame, called castle capes; (6) the crosswise beam attached to the top of the castle capes. called the top castle.

This framework is securely fastened together to support the movable parts of the loom, namely, (7) the warp and cloth rollers below the back and breast beams; (8) the heddle bars or frames suspended from the top castle, to provide for the raising or lowering of alternate warp threads; (9) the swinging beater or frame that holds the reed in place midway between the castle capes and the front of the loom.

Depending upon the construction of the loom the beater may swing from an overhead bar or from the lower side beams of the loom by means of additional upright supports called swords; (10) treadles attached to either the front or back stretcher beams; or hand levers usually attached to the castle capes; (11) lams—for greater variation in the tie-up of the treadles to the heddle frames another set of bars, stretching across the width of the loom half way between the treadles and the heddle frames, is often used. These are known as lams.

The reed is threaded or sleyed according to the desired closeness or looseness of the weave as well as the spacing of the spaces, called dents, contained in it. A coarse reed can be sleyed with two or more threads to a dent, but a fine reed very obviously cannot be used for coarse yarn.

Such looms, although widely distributed on all continents, are by no means the only kind on which hand weaving is done.

Nearly every type of loom ever devised, from the crudest to the most elaborate, can be seen in daily use in some part of the world. These may consist of merely a single length of wood, cut from the limb of a tree or sturdy bush, around which one end of each warp thread is attached, all of them together forming a horizontal row. All the ends of the opposite side are tied together in one group to the trunk of a nearby tree or to a stake set in the ground for the purpose. A loop of cord or a belt is then tied to one end of the wood, which is placed horizonitally in front of the weaver, and the cord extended around the back of his waist and tied in place to the other end of the log or branch. By sitting on the ground with his single bar loom strapped around him the weaver can adjust the warp to the required tension as he slides along the ground with the progression of the weaving. Looms of this type, whether only a front bar or a bar at both ends of the warp is used, are called back strap looms.

When only a very short length of warp is needed for small bags, mats, or belts, a thin, pliable bough of a tree or bush may simply be cut and bent in the form of the letter O or U for a frame on which to stretch the warp. By stretching and tying two cords across the upper and lower extremes of the O or U the warp can be fastened to the cord in a single, continuous thread or in separate short strands, in parallel rows

A somewhat more advanced form of loom is one made of 4 logs or beams securely fastened together, similar to a picture frame. Such looms may be used in either a horizontal or vertical position and are used extensively in many areas for tapestry and rug weaving. The starting end of the thread or cord used for the warp is often fastened to one of the end beams and then wound in a continuous length across the frame from the front to the back beam, or from bottom to top according to the position in which the frame is held, instead of each strand being cut to the required length and all the cut ends tied at the required tension to the front and back beams.

The even spacing of the warp is obtained in some locations by simply twisting a separate length of string around each warp thread. With the length of string doubled, one half to extend underneath the width of the warp and the other half on top, the looped end is placed at the outer edge of the first warp thread and the two cut ends crossed as they are passed between successive pairs of warp threads, in much the same way that a shoe is laced. If the threads are to be closely spaced a fine string is used and a single twist or cross made between each warp thread; for a widely spaced warp a heavier string is used and two or more twists made between the pairs of threads.

It was for this purpose of spacing the warp that the framed comb or reed was originally developed. With the use of the reed it became necessary to cut the ends of the warp in order to draw each alternate warp thread through the dents, thus necessarily eliminating the custom of making selvedges at the ends of the cloth as well as at the sides.

Selvedges.—A word derived from self edges, selvedges are the woven edges of the cloth that are held in place by the loops formed in reversing the direction of the warp and weft for each successive row. When the warp is wound in a continuous, uncut length across the front and back beams of looms not equipped with a built-in reed and harnesses, as in the case of most vertical looms, the looped ends can be closely woven to their full extent after the main part of the web has been completed and removed from the loom, to make a perfect selvedge at each lengthwise end of the cloth.

The last warp thread at each side of the web guides the evenness of the side selvedges as the weft is looped around them when passed from side to side across the warp.

Only side selvedges can be made when the ends of the warp are cut for the purpose of threading the loom.

Roller Beams.—Horizontal looms seem to have been favored in Asia and from the improvements made on them during many centuries have come those with which we are familiar today. To the first simple frames mounted on a stand made of four posts or stones were added, at a very early date, back and front beams that could be turned at will for rolling on them the supply of warp, and the cloth as it was woven. This appears to have been the first of the four important advances in loom construction, but is still not used by all groups.

Heddles.—Since the action of interlacing is that of drawing one group of alternate warp strands away from the other to produce an opening or shed between the two layers, through which to pass a crosswise weft or binding strand, it became important to effect a method that would permit all of one layer of alternating threads to be raised at one time. Thus much previously wasted effort could be saved by a single, mechani-

cal motion when fabrics requiring many warp threads were needed. This was accomplished in several ways. One was by the use of two twigs or rods that were somewhat longer than the width of the loom. The first rod was passed across the width of the warp, over and under each alternate thread, to form and maintain a shed opening between the two layers of warp threads. On vertical looms this rod was held in place by braces attached to the side beams of the loom. The second rod was laid across the top of the upper warp layer and a separate cord of the proper length loosely looped under each warp thread of the lower layer and fastened as well to the rod above the warp. In this way the loosely looped warp threads could be pulled to the required distance above their normal level by pulling the rod upward, to form a second shed of the warp. By alternating the sequence of the shed openings for each row, the weft could be locked in place. It is the method used today for the rugs woven by the American Indians and for other forms of tapestry done on vertical looms. The rod is called a heddle or heald rod, and the loose loops are heddles. This was the second major improvement in loom construction.

In some areas the demand for cloth led to still other solutions of the problem of time and labor saving that through experiment resulted in the use of a separate, permanently suspended threading arrangement for each of the two layers of warp threads. These threading arrangements were comprised of a series of heddles, mounted individually on bars or frames across the center of the width of the loom, through each of which a single warp end was threaded. For special purposes several warp ends may be threaded through each heddle.

As has been indicated, heddles were originally merely loose string loops, laced under alternating warp threads and around a wooden rod to enable the weaver to separate the warp into two layers. From this process heddles have more commonly become separate loops, each containing three openings—two for mounting it on the heddle rods and one for holding the warp thread in place.

They are usually made of string or cord of linen, silk or cotton; or of either flat steel or twisted wire.

Those of string are tied by hand on a pegged gauge made for the purpose. The two long, end loops used for mounting are known as doups and the short center loop is called the eye. Those of metal are generally made by special commercial machines. In this case the two end openings are called slots, the center opening of all heddles is called an eye.

Some heddles, used extensively for silk weaving, are made of two cord doups with a detachable glass or porcelain eye in the center. Until 1812 when John and Patrick Clark of Paisley, Scotland, perfected a method of making a suitable cotton cord, silk and linen were the fibers most generally used for heddle cord.

Harnesses.—The separate bars on which the heddles are mounted across the width of the loom are called heddle bars. When narrow, joined frames are used for the purpose they are referred to as heddle frames In the United States two bars, for the upper and lower heddle loops, or a single heddle frame constitute a harness when supported in position on the loom. A two harness loom, therefore, has two sets of heddle bars or two frames; while a four harness loom consists of four sets of bars or four frames and so on, all looms being designated by the number of harnesses provided.

This differs from the British meaning of a harness for which two sets of heddle bars or two frames comprise a harness. A two harness loom in Britain, therefore, generally means one having four sets of heddle bars or frames. The equivalent of the American two harness loom being designated as a two shaft or two way loom.

Heddle-Reed Combination.—Among some groups the principals of the rod for separating the warp into layers and the framed comb were combined into one by burning or drilling a small hole through the center of each tooth of the reed to form a straight row across its width. Starting at one side of the reed the cut ends of the warp were passed in successive order through a slit between the teeth and then through the hole burned into the tooth, for the width of the warp. By raising or lowering the threaded reed by hand the shed separation between the alternating threads could be made. In this way three important details could be dispatched by the use of one implement: the even spacing of the warp, the separating of the alternate warp threads and, by a sharp forward and back motion of the reed, the beating together of the woven weft rows.

Sword Beater.—When it was found that an entire row of alternate warp threads could be raised at one time, the manner of beating the woven rows together changed, in some sections, from the use of a forked stick or comb to a flat, pointed, thin edged, wooden stick rather than a framed comb or reed. This was passed through the shed opening to beat the weft into place. Such sticks vary in size and design in different localities, but since they were often made to resemble hunting knives or swords they became known as swords.

Treadles.—In the course of time treadles or foot levers were added to the constant improvements being made, to further simplify the raising or lowering of the heddle bars or frames and to provide the fourth important advancement in loom construction.

The combined use of hand and foot power has always been more widely practiced in the East than in the West, and there are many interesting examples of how foot as well as hand motions were applied to the details of this craft in Asia where treadles have been used for thousands of years. One resourceful system, still to be found occasionally, requires the use of only two strings, one end of which is tied to each of the two suspended heddle bars while the other end is tied at the required distance to the large toe of each of the weaver's feet, enabling him to pull the heddle bars down at will.

In India the treadle development included a shallow pit dug into the ground beneath the loom to accommodate the treadles which were placed in the pit. The dark ground patches shown in illustrations of some Indian, African and Chinese looms generally indicate the use of these pits.

The manner in which the action of the treadles or hand levers causes the layers of warp to separate identifies the loom as one of two types; the *counter balanced* loom in which both layers pull away from each other equally in opposite directions from a central level; and the *counter march* loom in which only one of the layers is pulled away from a central level.

The treadles of most floor looms cause the

harnesses to be pulled downward; the hand lever action of most table looms, those which can be placed on a table for weaving, causes the harnesses to be raised. Floor looms in which the construction causes the harnesses to raise when the treadles are depressed are known as *jack looms.*

Each improvement necessitated a change or addition to the framework of the loom and in some areas the single rod or flat square frame became a large, sturdy, boxlike frame (already described) to accommodate the harnesses and treadles. But even today there are looms being used that are no more than a few rods or sticks held together only by several lengths of knotted string and on these the skill of an occasional weaver produces fabrics of outstanding quality and design.

Patterned Fabrics.—The formation of a pattern is made possible by the raising or lowering of certain separate warp strands or groups according to a predetermined plan. This is the basis for all weaving. Thus the early division of the warp into two layers soon led to more divisions as designs were introduced into fabrics. A method of doing this was to pick up as many threads across the warp as were needed for a particular part of a pattern and keep these in order at the back of the loom by inserting another rod between them and the remaining warp threads. By moving the rod forward when it was needed a temporary pattern shed could be formed in the warp to simplify the passage of the weft. As many as 20 or 30 such rods could thus be used for the various parts of a pattern, all remaining at the back of the loom when not in use. Each time a certain portion of a pattern was needed the warp threads that formed that portion had, heretofore, to be raised individually and other ways were therefore evolved. It was evident that by threading these warp threads through a different group of heddle loops the pattern could more readily be woven. In this way the use of many rows of loops was developed, with a corresponding number of foot pedals or hand levers to expedite their operation.

Some of the intricate designs in many colors required the raising or lowering of more groups of warp threads than even the additional rows of heddles permitted. This is apparent in the samples of magnificent ancient Persian, Indian and Chinese fabrics that have been preserved for our inspection in numerous museums. For these patterns the many rows of heddles were used in conjunction with various systems of extra cords attached to special individual warp threads.

In China, after silk weaving was introduced on an organized basis about 4,000 years ago, a loom was developed that made it possible to raise each delicate silk warp thread separately or groups of them together. This was done by attaching additional weighted silken threads to each warp thread by a series of extra heddle loops and extending them vertically from the bottom of the loom to the framework at the top. These additional threads or cords were drawn into position by an assistant who was called a draw-boy and the loom was known as a draw-loom. The resultant effect was very complex in appearance but produced beautiful fabrics of intricate patterns when operated by skilled weavers.

Vertical Looms.—These were used to a marked degree in Egypt, Greece, Rome, Scandinavia and England during the early periods of European history.

In Egypt and Rome both ends of the warp were attached to the lower and upper beams of the vertical looms just as they are in many places today and the weaving done from the bottom upward.

In Greece and some of the northern European areas, however, the weaving was done from the top downward. The upper end of each warp thread was secured to the upper beam, but the lower end was left unattached, the proper tension being obtained by the use of clay or stone weights fastened to each separate warp thread or to a number of them tied together in a weighted group.

Just how this latter detail was managed in the case of long warps such as those needed for the many yards of cloth from which the costumes of the era were made is not clear. Since the only examples of Greek looms are a few pictured on bowls and vases and these indicate long lengths of finished weaving rolled on the upper beam, there must have been a similar method of rolling the warp supply on the lower end of the loom as well, or fastening it in some other way, but the method used has not yet been determined satisfactorily. Nor does it seem probable that sufficiently heavy weights could be attached to fine threads to keep them at the tension required to obtain an even beat without breaking them. In Greece particularly, vertical looms reached a high state of development. Both in Iceland and in northern Alaska warp weighted looms were used until very recently and may even now be found in isolated areas.

Today vertical looms are used principally for tapestry weaving. In this technique the warp is entirely covered by the closely beaten weft. The figures and scenes depicted in tapestries such as those from the celebrated weaving centers of Europe must be woven in a sideward direction, across the width of the cloth, not in an upright direction as the finished work appears to the observer. Examination of some of the famous museum pieces will ascertain this point, the direction of the ridges made by the warp threads being clearly visible in them. A great deal of tapestry weaving is now done on two harness horizontal looms.

Fibers.—Of the almost endless list of natural fibers that have been experimented with since looms were first set up, linen, wool, cotton and silk seem to have supplied the greater part of the need for weaving yarns. And, as far as there is any record, the use of these evidently originated in the East; linen in Egypt; wool in Mesopotamia; cotton in India; and silk in China. It does not prove conclusively, however, that they were not also known elsewhere. Cotton garments, for example, found in Utah and other western states, are believed to antedate the Christian era.

The bark, roots, leaves and stems of scores of trees and plants were and still are prepared in both spun and unspun forms for weaving in many areas. Notable among them is bamboo which is adequate not only for weaving but often supplies almost every need of daily living in Asia. The advantages of asbestos as a fabric were long ago known in China and Egypt. In China, among its other purposes asbestos was sometimes woven into cloth for lining the cuffs of the Chinese wide sleeved jackets and coats—such linings when removed could readily be cleansed in a fire and replaced, clean but unharmed, when needed.

Metals were not a neglected element in weaving either, although their earliest use was of much

more recent date compared to plant and animal fibers. Gold and silver that had been drawn into wire or hammered and cut into narrow, thin strips are said to have been introduced into weaving by a ruler of central Asia about 1200 B.C., and these combined with the beauty of silk gave rise to one of the most fabulous industries in history. Much fine weaving, however, had been done before sericulture or silk production was organized in China by the emperor Huang-Ti about 2700 B.C.

Not only was the step from unspun to spun fibers dependent upon the intellectual levels of the various groups, but was dependent as well on the available source of supply within each area, and on accepted rites and customs. It is doubtful that there are any remote tribes who do not know how to spin. It has been found, however, that among certain of the more primitive people, weaving in any form is unknown.

In hand weaving are involved the spinning and measuring of the yarn and the preparation of the loom. Many fibers are, of course, used in their natural form, unspun. But where long lengths of thread or yarn are needed the spinning in most cases is done commercially. Sometimes, however, all the attendant steps must be done by hand.

In order to spin, the natural fibers must first be prepared by removal from the plant or animal and by cleaning. There is considerable variation in the way in which these details of the work are undertaken not only for different fibers but for similar fibers among the groups who use them. Sheep's wool is generally cut; camel and kashmir goat hair are never cut but collected during the moulting season when the hair falls from the animals in chunks. Angora rabbit's fur may be plucked out by hand or cut.

Cotton is part of the seed pod of the plant and is usually pulled by hand although machines do part of the work. Flax of the finest type is nearly always pulled by hand and the delicate roots pulled with the stems to add to the length of the fibers.

Silk must be freed from the silkworms' cocoons by soaking them in hot water.

The second step in spinning is that of cleaning the fibers. Among some groups, fibers such as wool or cotton may simply be picked clean by pulling the dirt particles off by hand. Among other groups more elaborate methods of washing and combing are customary.

Linen, ramie, jute, hemp and other similar fibers taken from the stems of plants are known as bast fibers and these require the soaking of the stems in water to loosen them from the core and outer bark of the plants.

Spinning.—The spinning itself is a matter of twisting the fibers together to make as continuous a length of the required fineness or thickness of yarn as possible. As in all the steps connected with weaving every method that has been devised, from the simplest to the most complex, is being used today—all involve pulling successive groups of matted fibers out to the required fineness or thickness and twisting them into a continuous strand of yarn or thread. (See article SPINNING for complete process.)

The basic principal of a spindle is a thin rod or twig which, when attached to one end of an extended fiber and suspended in mid-air, will revolve, thus causing the length of fiber to wind around itself. The extremely fine thread used for the famed Dacca muslins of India was spun on the most delicate of these hand spindles, never on the more advanced spinning wheels. Indeed, so finely spun was the thread that it was necessary to rest the lower end of the spindle in a shallow shell or disk to prevent the weight of the spindle from breaking the thread. This simple device, transcending through many changes including the addition of a disk near the lower end of the spindle, has become familiar in the spinning wheel, which seems to have made its first appearance in India. The modern, low, treadle wheel, used particularly for flax, was developed in Nuremburg in 1533 * and is known as the Saxony wheel. The high wheel used in colonial days mainly for wool, is called the Jersey wheel.

Winding the Warp.—With the yarn at hand the weaver must approximate and measure the amount needed for the cloth to be woven. This is referred to as winding the warp and is the second part of the process called dressing the loom, the first being any necessary adjustment to the loom itself. The size and type of loom used as well as the fineness or thickness of the yarn determine the amount of warp that can be accommodated at one time. The greatest length is usually dependent upon the distance from the front and back upper beams to the top of the rollers or winding beams. The width is determined by the width of either the reed or the heddle frame, whichever is the narrower.

As has been pointed out the number of warp threads contained within the limitations of the width to be woven may vary according to the spacing of the warp in the reed, thereby resulting in a closely or widely woven fabric.

The number of threads thus contained in the width multiplied by their length equals the entire length of yarn needed. From this amount each warp thread of the desired length must be measured equally, and for the purpose a gauge of some sort must be used. The gauge may be two pegs or stakes set apart in the ground at the necessary distance; it may be a frame or board around the sides of which a row of pegs has been set by means of holes drilled into the wood; or it may be an upright revolving frame or cylinder called a reel, around the circumference of which the yarn is wound. During the process of winding, the alternating threads are crossed at an angle as they pass each other, to facilitate the threading or drawing-in of the loom later. Sometimes the warp is crossed at two points; the first near the first peg of the warping frame, is known as the porrey cross; the second, near the last peg used is known as the portee cross. For convenience in counting the number of threads needed, a string is generally tied around each group of 25 or 50 threads until the required number have been wound.

When the warp has been entirely wound, the cross, called a leash, is tied in place with a temporary string which is later replaced by two sticks, called leash sticks. The two extreme ends of the warp where they loop around the first and last pegs are also temporarily tied with a string to accurately cut the strands for the threading process. The entire group of measured threads in this form of warping are fashioned into a loose, easily retractable chain to prevent it from entangling until it has been drawn in on the loom.

---

* Some authorities say 1530.

Another form of warping is done by the use of large frames or stands that have been constructed with bars or racks containing removable spools. These spool racks are called creels. Each spool is carefully wound with the appropriate amount of thread and the threads from as many of them as are needed at one time, wound on what is called a sectional warp beam, that is, a warp beam or roller that has been constructed in a number of even, movable sections which are mounted horizontally on a central axle. Each of these sections is revolved the same number of times to assure an even length of the entire warp, the cut ends being held in place with Scotch tape, or other adhesive binder, until they are ready to be threaded. The process is called sectional beaming or sectional warping. All color changes and patterns to be woven must be considered before the warping begins.

Drawing-In.—The threading or drawing-in of the loom is the last part of dressing the loom and is done according to a predetermined plan. If only two rows of heddles are to be used, as for a plain cloth, the threading of the heddles is simply a matter of evenly alternating the two rows —the first thread in row 1, the second thread in row 2, and so on. If the pattern is complex, involving the use of many rows of heddles and often thousands of threads, great care must be taken in threading the heddles according to the design. Such designs are generally sketched out in draft form on graph paper to avoid the possibility of making threading errors which even the most skilled weavers are subject to. To make a draft is to darken certain squares of the graph paper, or notate in some other understandable manner the lines and spaces that represent the weft and warp threads. This enables the weaver to raise or lower the heddles in the sequence required for continuity of the pattern.

Among some groups sketched patterns are not used at all, the design simply following the imagination of the weaver. This fancy-free method while sometimes resulting in designs of unusual interest and excellence more often results in fabrics that would have been considerably improved by an adjustment made on a paper sketch.

The threading, if the chain method of warping has been used, may be done from either the front or back of the loom. The object is to wind the warp around the warp roller or beam; therefore the warp must be secured to the warp roller or beam by a rod or other device that is connected to it and can be turned with it. With the warp evenly wound on the warp roller and the threaded, cut front ends extending to the upper front beam the winding ceases, to permit the even tieing of the front ends to the rod, stick or cloth attached to the cloth roller over the top of the breast beam.

When the sectional warping method is used the loom is drawn in and sleyed from the back and then tied to the front roller in the same way as the chain method.

Various extra appliances such as a raddle, which is temporarily attached to the back beam, for evenly spreading and maintaining the warp at the required width of the fabric while the threads are being wound and drawn-in; and a gauge, known as a temple, to keep the width of the woven cloth stretched at the desired tension in front of the reed as the weaving progresses, are also used by many weavers to aid them in producing accurately proportioned webs.

Woven Cloth.—Although the ever increasing exchange of ideas and techniques has long since brought about a very broad similarity in the weaving of all nations and each copies the designs of others, there still remains that individual difference of fiber preparation, pattern, style and workmanship that lends distinction to the textiles of each and labels them, in effect, to the informed observer, as its own. We associate certain fabrics with the nations in which they originated or were produced to a notable degree. For example; plaid designs have been used since early antiquity in many areas, but the particular way in which they were patterned and woven in the Scottish Highlands has come to identify certain plaids everywhere as Scotch plaids or tartans.

In a like manner, the fabrics of India, China and Guatemala, to mention a few others, clearly indicate and identify some of the variations of artistic preference and general characteristics of each nation.

There are three main categories into which woven cloth is divided. These are (1) plain or tabby weaves; (2) twill weaves; (3) satin weaves. Within these three come an infinite variety of plain and patterned fabrics from the plainest muslin such as that used for sheeting or in finer qualities for sheer handkerchiefs to the most elaborate brocades or other ornamented textiles.

Tabby or Plain Cloth.—Tabby weaves are recognized by the even under 1, over 1 interlacing of alternate, single warp and weft threads which requires only two shed separations. This even alternation makes tabby the most easily woven of the three main types of cloth.

It is more widely used in all parts of the world than any other form of weaving and includes, in addition to sleeping mats, floor coverings, blankets, saddle bags, boat sails, etc., fabrics for wear and decoration such as gingham, cretonne, chintz, flannel, cheesecloth, broadcloth, seersucker, taffeta, chiffon, pongee, Shantung, homespun and some tweeds, to illustrate a portion of its uses.

When two or more colors or types of yarn are combined in a tabby fabric, designs in stripes, checks and plaids may be arranged, the elaborateness of which may be as varied as the needs of their users.

Another variation of plain tabby is achieved by the use of two or more sizes of yarn to obtain a ribbed or corded fabric such as seen in poplin, piqué or grosgrain ribbon.

Basket weaves, also, are a form of tabby for which two or more warp and weft threads, rather than single threads, are alternately interlaced.

Plain tabby is the basis for the majority of special pattern techniques, adding firmness and strength to the cloth. It is woven as part of the pattern in techniques similar to "laid-in," or between the pattern rows in those similar to the "overshot" designs of colonial coverlets and the various forms of brocade in which the weft spans or floats across several adjacent warp threads. The primary difference between "overshot" and "brocade" techniques is that overshot designs are planned on the overlapping by one thread of adjoining blocks or squares, while brocade may take any formation or placement desired.

In addition, overshot patterns are woven with the right side toward the weaver. Brocades, which provide us with some of the most beautiful fabrics made, are woven with the wrong side toward the weaver, the right side of the pattern

appearing on the under side of the web. This is due to the fact that it is simpler, in this case, to skip over the top of warp threads for a pattern than under them as would be necessary to weave the pattern right side up. Also, the fewer threads raised the less wearing it is on the warp.

Twill Weaves.—These may generally be identified by the clearly visible diagonal lines of the fabric. The overlapping of the weft in successive rows makes twill stronger than tabby when both are evenly spaced.

The weave is based on the alternation of at least three adjacent warp threads in which the weft passes under 2, and over 1 or vice versa according to the effect desired.

A four harness twill produces a diagonal or angle of the most equal proportions and is used for the majority of twilled fabrics, as, for example, the well known and popular Scotch plaids or tartans.

By raising or lowering the heddles, as the weaving proceeds, to rearrange or reverse the even sequence in which these units are threaded, a great variety of herringbone, diamond and other novel effects may be produced in either a widthwise or lengthwise direction. For example, instead of a consecutive 1, 2, 3, 1, 2, 3 order, a 1, 2, 3, 2, 1, 2, 3 sequence will result in a broken or herringbone pattern. Serge is produced by a diagonal sequence of under 2, over 2, and so on. Other twill fabrics are denim, gabardine and foulard.

Satin Weaves.—Basically a twill weave although the twill pattern is not visible, at least five harnesses are required in weaving satin and as many as twenty-four may be used. Of Chinese origin, it is a very close weave based on an even rotation of as many harnesses as have been threaded.

The weft is passed over 1 warp thread and under the remaining number in each pattern unit. This results in floated or loose warp threads throughout the surface of the fabric to create the nearly unbroken line that gives satin its appearance of a smooth, uninterrupted surface. Like brocade satin is woven face downward.

Loop and Knot Weaves.—These two other important techniques are familiar in pile fabrics —those having a raised surface.

In the loop weave a tabby shot is made, the thread for this shot then being looped, between the warp threads, around a thin rod or gauge which is glided across the top of the warp for that purpose. There are many uses for loop weaving, perhaps the best known among them being bedspreads and rugs. The loops may either be left as they are woven or the top edges cut off to create an appearance of softness and depth as in velvet or chenille.

The knot weaves are usually identified with Oriental rugs but are also used by some weavers for decorating special fabrics such as those made for draperies and upholstery. The two knots used principally in this form of pile weaving are the Ghiordes or Turkish knot and the Sehna or Persian knot, each being the name of the respective weaving centers. They are woven, in the Orient, on vertical looms.

Each knot is made separately by twisting the weft thread around the proper warp threads to knot it in place, the loose weft end then being cut to the required length before the next knot is made, and one or more rows of plain tabby or twill woven between the knotted rows.

Besides these, there are many other methods of weaving rugs or carpets by hand.

Lace or Gauze Weaves.—These weaves are generally achieved, in their simplest form, by twisting the threads of the lower tabby layer over those of the top layer by means of a thin, flat, pointed stick or similar device and pulling one or more rows of weft through the twisted threads. The process is repeated as often as necessary or combined with plain or twilled weaving, to produce the length of gauze required. These weaves can also be made on multiple harness looms by a special threading arrangement.

HISTORY

Hand weaving is one of man's most ancient and fundamental skills. Exactly where it started or how it came about can only be conjectured since no fragment of history is old enough to provide positive assurance on these points. If there was a single place of origin for the art of weaving the evidence at hand would suggest that Asia was that place. Certainly most of the progress in the craft has evolved from there. But there seems little doubt that the need for cloth was recognized almost simultaneously in widely separated areas and that the solution to so basic a problem could not have deviated greatly, except in the relatively minor details of mechanical execution.

As is to be expected, many of these details were more quickly and ably bridged by some groups than by others. In fact some groups seem never to have acquired the desire or ability to weave at all as, for example, throughout much of Polynesia and Melanesia where cloth is made by the beating of bark and plants.

If man needed an example of the principle of interlacing there were many such examples in nature to choose from. Vines will become entwined and interlaced as they grow. Many animals, birds and insects instinctively form their nests by a method of locking together or weaving the twigs and strands of grass, straw, feathers and other fibers they gather. And who is not aware of the skill of the spider in the construction of his web.

The oldest fabric samples known have been unearthed in the excavations made during the 19th and 20th centuries in Europe, particularly from the dry lake bed regions of Switzerland, the Nile Valley in Egypt, Peru, and from the oak tree coffins of northern Europe. They are variously dated from as far back as 12,000 years to the Stone Age to about 2000 B.C.

Excavations made in the Nile Valley in Egypt have provided us with samples of linen, some of which are believed to be about 6,000 years old. One of these is said to be of tan thread so fine and closely woven that it contains more than 250 double warp threads to the inch. Wool and other fibers were also used in Egypt.

From the oak tree coffins of northern Europe, dated to the 2d millennium B.C. we have evidence of the use of wool as well as linen. This does not mean that wool was lacking or unknown elsewhere in Europe, simply that prevailing conditions were not conducive to its preservation in all areas or that circumstances have not brought it to our attention.

In the Western Hemisphere an antiquity of weaving almost equal to that of Egypt has also been authoritatively established by archaeologists. Peru is the principal site in this half of the

world and from the profusion of textiles found we have firsthand knowledge of the unusual skill of ancient Peruvian spinners and weavers. There, as in some European and Asiatic areas, nearly every form and technique of weaving seems to have been known. The earliest of these pieces, made of cotton to which maguay or a similar fiber has been added, is believed to be about 4,500 years old and is the oldest sample of cotton weaving known. Ancient as well as present-day Peruvian spinners were familiar with at least six distinct colors in which cotton grew. These ranged from tan to reddish brown and gray.

Remnants of cotton in North America have also been found. One of the most ancient of these is a piece of tapestry thought to have been woven prior to the Christian era in what is now the State of Utah. It was found in a dry cave in Grand Gulch. Skeins of cotton and woven articles discovered during explorations of the cliff dwellings of the southwestern United States indicate the knowledge of weaving in that section also. Only from rare discoveries such as these and their relation to other known prehistorical facts can scientists determine the approximate antiquity of man's ability and progression.

Trade is, of course, the major incentive in progress of any kind. But conquest and subjugation have also had an important share in the strides made in the art of hand weaving. The outstanding skill of certain individuals is admired and appreciated among all groups, whatever their fields may be; thus it was not long before a trade was established in some areas to supply the demands for the products of such individuals. Often neighboring tribes not concerning themselves with trade would simply overpower a weaker neighbor and take by force the workers and articles they wanted. As the need for cloth grew greater both trade and conquest continued.

Each country, each province had something different to offer in the quality and beauty of its fabrics. Each guarded its techniques with care while trying to wrest the secrets from the others.

Many centuries before the advent of Christianity a thriving if hazardous business was being conducted between Egypt, the various provinces of India, Arabia, Syria, Byzantium, China and other Asiatic areas, and parts of Europe, particularly along the Mediterranean.

Every weaving technique known from the plainest to the most unusual combinations was used and others evolved and improved. Loom improvements or changes were an important part of the advances made in perfecting the textiles. Without these changes it would not have been possible to produce the endless yards of cloth increasingly demanded.

One of the most unique achievements in loom construction was the Chinese draw loom perfected, according to available records, about 1300 B.C. Made for weaving the dainty, beautifully patterned silks of China, it is the forerunner of the European draw looms on which so many magnificent fabrics were made during the 9th to 18th centuries.

In Asia and Egypt rigidly controlled factory systems developed that caused many of the harassed and ill treated weavers, as well as those who sought adventure, to search for safety and freedom elsewhere. With no overland route open to them except toward the west, Europe and North Africa were their inevitable goals.

The most notable fabrics of early Europe were those of Greece and the surrounding areas. Both wool and linen were woven in Greece by ladies of all classes and nearly every household. To a lesser degree weaving was also a home occupation in Rome, but in both these countries the textile demands for luxury at home and by the armies abroad were supplied chiefly by the factory systems that so often brought misery to the enslaved workers, and in addition by imports from Egypt and the East.

During the 6th century A.D. silk culture was introduced into Europe by the successful mission to Asia of two Nestorian monks of Mt. Athos. Constantinople is said to be the city in which sericulture became a new enterprise for the western world.

Linen, wool and cotton were all in constant demand for many types of fabrics, but it was silk, more than any other fiber, that brought about the incredible volume of trade that arose wherever its elegance was known. For a time, among those who could afford its luxury, there was scarcely any purpose for which silk was not used, whether for personal adornment, household items, banners or horse caparisons.

When the exploits of Mongolian marauders closed the Eastern sources of supply to Europe in the 13th century, much of the power of Arab trade was lost. Italy, then a wealthy trading center, was able to meet the requests of her neighbors and others for silk. By the 17th century, when first place in this field went to France, Italian silks were as highly prized as those from the Orient. Both Italy and France still make some of the finest textiles woven.

The extravagance of royalty and its followers as well as the church in nearly all of the European countries during these and the following centuries is well known and this extravagance was strongly evidenced in the magnificence of the textiles used, just as it was in Eastern lands.

From time to time laws regulating the making and use of these costly fabrics were proclaimed, but were soon ignored by those of wealth who were indifferent to the plight of the general populace.

The weaving guilds during the rise of the weaving industry in Europe had become highly organized, rigidly controlling each minute detail of cloth production by its members whether the work was done at home or in one of the many large shops of the period. The type and quality, and washing and dyeing of the fibers; the width of the cloth; the number of shots to the inch; the finishing, and the pressing and weight of each piece were even more completely inspected than the best fabrics today, and woe be the worker whose work was not up to standard. Only in his few spare hours after the long day's toil was over could a weaver make the cloth he and his family needed.

A great deal of excellent weaving was, of course, being done throughout the entire Western Hemisphere by various groups of native Indians and Spanish settlers. The extent of its trade, however, seems to have been almost negligible compared to that of other continents, especially in North America.

It is a point of interest to note that not only in their spinning, weaving and implements of general use, but also in appearance, so closely did some of these Western people resemble the inhabitants of far distant lands as to strongly suggest a mutual origin. This is evident, for instance, in the case

of the ancient Peruvians who bear close resemblance in all the named points to the early Egyptians. The route by which they and others may have come seeming quite logically to be via the southern Pacific expanse that takes in some of the South Sea Islands. A number of books and theories have been written on this subject.

The early North American colonists do not seem to have been familiar with the weaving techniques of our western Indians or of Central and South Americans, the samples of their work that remain all being similar to that of northern Europe. And, understandably, they had very little time for weaving experiments when coping with the problems of a new frontier. At a later date some very excellent fabrics, including many of silk, were woven by those colonists who were skilled in the art.

More than a century after the first colonists arrived in North America the use of power machinery to replace the hand looms became an established fact. Many experiments had been made in this direction throughout the long history of weaving, and there is evidence, though scant, that power machinery of some kind was known in the Mediterranean area prior to the Christian era. This knowledge seems, unfortunately, to have been forgotten, and the point must await adequate scientific research for definite proof.

Because it was a household occupation in Europe, most of the American colonists were familiar with spinning and many with the weaving of cloth so necessary to their well being in the new world. It was not long, therefore, before looms were set up. Those looms were large cumbersome affairs that would be unsuited to most of our dwellings today, although they are still used occasionally in country homes.

Sheep and flax were raised and small amounts of cotton were grown from seeds brought from Europe. The various fibers were hand spun and hand woven into the blankets, sheets, pillow tickings, suit cloth, and so on, needed for home and personal use.

In an effort to foster and protect her home industries and products England demanded the weaving of cloth by the early settlers. Toward this end importations of both the raw materials and finished fabrics from other European nations were prohibited. Even a silk industry was begun. At that time the culture of silk was considered a more important industry than cotton growing. Grants of land and other special compensations were extended to those southern planters who were interested, while in some cases fines were imposed on those who did not grow 10 mulberry trees on each 100 acres of land for the feeding of silkworms.

Today many of the best textile mills find it expedient to employ hand weavers to work out the designs they are considering before the power machines are set up. In this way much uncertainty is forestalled and time and money saved.

Hand weaving alone cannot supply the vast amounts of cloth necessary for the world's daily use, although in many places it is still the major source available. Machinery, on the other hand, is efficient only on a quantity basis, a requirement that does not gratify man's creative instincts or sense of beauty. These things must be satisfied by individual vision and effort. In fabrics they can be achieved only by the weaver's creative touch on the thread of his hand-operated loom.

H. J. Brown,
Author of "Hand Weaving for Pleasure and Profit."

WEBB, Alexander Stewart, American soldier and educator: b. New York, Feb. 15, 1835; d. Feb. 12, 1911. He was graduated from West Point in 1855, was assistant professor of mathematics there in 1857–1861 and entered the Civil War as major of the First Rhode Island infantry; served at Fort Pickens; at the First Battle of Bull Run and in the Peninsular campaign rising to the rank of brigadier general of volunteers in 1863. He was awarded a Congressional Medal for gallantry at Gettysburg, was in the Rapidan and Wilderness campaigns, was wounded at Spottsylvania and on his return to duty was appointed chief of staff to General Meade. He received brevet rank as major general of volunteers in 1864 and was brevetted brigadier general of regulars in 1865. In 1866 he was promoted lieutenant colonel, was brevetted major general in the regular army in 1869, retired in 1870. He was president of City College of the City of New York from 1869–1903 and wrote *The Peninsula: McClellan's Campaign of 1862* (1882).

WEBB, Sir Aston, English architect: b. London, May 22, 1849; d. there, Aug. 21, 1930; educated in private schools, articled to Banks and Barry, architects, and began practice in 1873. He was the architect for the completion of the Victoria and Albert Museum and the Royal College of Science, South Kensington; the Britannia Naval College, Dartmouth, and the architectural accessories for the Victoria Memorial before Buckingham Palace. He designed many churches, commercial structures and mansions, and, with E. I. Bell, the Victoria Courts, Birmingham; the Birmingham University and the new schools of Christ's Hospital. He was president of the Architectural Association in 1884; vice president of the Royal Institute of British Architects 1893–1897; its president 1902–1904; and president of the Royal Academy in 1919.

WEBB, Beatrice Potter, English economist: b. England, Jan. 22, 1858; d. Liphook, Eng., April 30, 1943; was educated privately and later engaged in investigating social conditions. In 1892 she was married to Sidney Webb (q.v.), with whom she

collaborated in preparing many works on economics. She served on the royal poor law commission in 1905–1909 and was joint author of the minority report. During World War I she served on the Committee in Aid of Distress; Statutory War Pensions; on Reconstruction; National Registration; on Machinery of Government; the War Cabinet Committee on Women in Industry; the Lord Chancellor's Advisory Committee for Women Justices. She wrote *The Co-operative Movement in Great Britain* (1891); *Men's and Women's Wages* (1919); *My Apprenticeship,* 2 vols. (1926; 1938).

WEBB, Charles Henry (pseudonym JOHN PAUL), American journalist and humorist: b. Rouse's Point, N. Y., Jan. 24, 1834; d. New York City, May 24, 1905. He was on the staff of the New York *Times* (1860–1863); founded and edited the *Californian,* San Francisco (1863–1866); later contributed to the New York *Tribune* humorous articles signed "John Paul." He invented an adding machine, but was better known by his burlesque dramas, among which are *Liffith Lank* (1867); *Saint Twel' Mo* (1868). He also wrote *John Paul's Book* (1874); *Parodies, Prose and Verse* (1876); *Vagrom Verse; More Vagrom Verse* (1901).

WEBB, James Watson, American journalist and author: b. Claverack, N. Y., Feb. 8, 1802; d. New York, June 7, 1884. He entered the United States Army as second lieutenant and became adjutant in 1825; served in the West under General Winfield Scott, and resigned from the army in 1827. In that year he became editor of the *Morning Courier* in New York; this was united with the *Enquirer* as the *Courier and Enquirer,* which he edited until 1861, when it was merged in the New York *World.* At first he supported Jackson but later as vigorously opposed Jackson's measures, and made the *Courier and Enquirer* one of the leading Whig papers. In 1851 he was appointed engineer in chief of New York State and given the rank of major general. After refusing an appointment as minister to Turkey, he was appointed minister to Brazil in 1861, which office he held until 1869. In 1865 when he was in France for a time, he negotiated a secret treaty with the emperor providing for the removal of the French troops from Mexico. He wrote *Altowan, or Incidents of Life and Adventure in the Rocky Mountains* (1846); *Slavery and Its Tendencies* (1856), and *National Currency* (1875).

WEBB, Sidney, 1ST BARON PASSFIELD, English economist: b. London, July 13, 1859; d. Liphook, Eng., Oct. 13, 1947. He was educated in Switzerland and at the City of London College, and in 1878 entered the civil service, holding several different positions, chiefly in the colonial office, and resigned from the service in 1891. He was admitted to the bar in 1885. He was one of the founders of the Fabian Society (q.v.), and in 1891 was elected to the London County Council as a candidate endorsed by the Fabian Socialists. He was lecturer on political economy at the London School of Economics and Political Science and was professor of Public Administration at the University of London.

He wrote *Socialism in England* (1890); *The London Programme* (1892); *Labor in the Longest Reign* (1897); *Grants in Aid* (1911); *Toward Social Democracy* (1916); *The Works Manager of To-day* (1917). He edited *How to Pay for the War* (1916); *Story of the Durham Miners* (1921); *Fabian Essays* (1920); and many works in conjunction with his wife, Beatrice Potter Webb (q.v.), among them *The History of Trade-Unionism* (1894); *Industrial Democracy* (1897); *English Local Government* (1906); *English Poor Law Policy* (1910); *The Consumers' Co-operative Movement in Great Britain* (1921); *The Decay of Capitalistic Civilization* (1921); *Soviet Communism* (1935). He was created Baron Passfield in 1929. In 1929–1930 he was secretary of state for dominion affairs and for the colonies in 1929–1931.

WEBB, Thomas, British soldier and Methodist pioneer in America: b. England, c.1724; d. Bristol, England, Dec. 19, 1796. He was an officer of the Royal American Army and saw service at Braddock's Defeat in 1755; at the storming of Louisburg, Nova Scotia, in 1758 and with Wolfe at the Battle of the Heights of Abraham in 1759. He was converted to Methodism by the preaching of John Wesley at Bristol, England, and was afterward licensed to preach. He returned to America on military duty and after 1767 preached in New York in alternation with Philip Embury. After his retirement from the army with rank of captain he devoted himself to the preaching of Methodism. He founded the first Methodist Society at Philadelphia and also established societies in New Jersey, Delaware and Maryland. After the outbreak of the Revolutionary War he returned to England and spent the remainder of his life as a preacher at Bristol.

WEBB, William Henry, American shipbuilder: b. New York, June 19, 1816; d. Oct. 30, 1890. He was educated in the grammar school of Columbia College, New York; learned the trade of shipbuilding in his father's yard; became manager of his father's business in 1843. Under Webb's management were built many ships of war for the United States and foreign governments, as the *General Admiral,* steam-frigate for Russia, two steam-frigates for Italy, the *Dunderberg,* ironclad ram for the United States government. In 1890 were erected buildings at Fordham, N. Y., for an "academy and home for shipbuilders," founded by Webb. The objects of the academy and home are:

(1) Relief of "aged, indigent and unfortunate men" who have been engaged in any department of shipbuilding in the United States; relief also of their widows. (2) Providing for American young men of good character gratuitous education in the profession of shipbuilding and machine-engine building, together with free maintenance.

WEBB CITY, city, Missouri, in Jasper County; altitude 1,003 feet; 6 miles northeast of Joplin; on the St. Louis-San Francisco, and the Missouri Pacific railroads. The region in which it is located was originally predominantly agricultural, and still has many fine farms; but when lead and zinc were discovered in a field embracing sections of Missouri, Kansas, and Oklahoma, and came increasingly into demand for commercial uses, Jasper County turned to mining. In the years of the first World War, Webb City and Carterville, its next-door neighbor—the two are known locally as the Twin Cities—experienced a considerable boom. After the war Webb City

developed new activities mostly centering on agriculture. Clothing, shoes, and explosives are produced; gravel for road building is made from the chats of the old mines. There is a Carnegie library. The town was settled and named for John C. Webb, on whose land the site was platted in 1875. It has a mayor and council. Pop. (1950) 6,919.

WEBB-KENYON ACT, was passed in March 1913, over the veto of President Taft. It prohibited the transportation from one state into another of intoxicating liquor intended to be used in any manner violating the state laws. Thus the federal protection which liquor enjoyed as an article of interstate commerce was removed and state prohibition was stimulated. By a decision of the Supreme Court of the United States of Jan. 8, 1917 the act was declared constitutional, thus ending a long controversy on the subject.

WEBBER, wĕb'ĕr, **Charles Wilkins,** American author and naturalist: b. Russelville, Ky., May 29, 1819; d. Nicaragua, April 11, 1856. In early youth he passed several years of adventurous life on the Texan frontier and in 1844 settled in New York as a journalist; for two years he was editor and co-owner of the *American Review* and a prolific contributor to several other magazines. He was a friend of Audubon, whose influence is noted in much of Webber's work. The first volume of his projected series *Hunter-Naturalist* was published in 1851 and the second and last in 1854 under the title *Wild Scenes and Song Birds.* His first story, *Old Hicks the Guide* (1848), was followed by the sequel *The Gold Mines of the Gila* (1849) and other tales of backwoods life and adventure.

WEBBER, Herbert John, American plant physiologist: b. Lawton, Mich., Dec. 27, 1865; d. Riverside, Calif., Jan. 18, 1946. He received the B.S. degree in 1889 and the master in 1890 from the University of Nebraska, and the Ph.D. from the University of Washington in 1901. From 1893 to 1907 he did research work for the Department of Agriculture on orange diseases and plant breeding; the latter subject he then taught at Cornell University and New York State College of Agriculture until 1912, when his association with the University of California began, which was to last until his death. He held there the posts of professor of plant breeding, of tropical horticulture, and of director of the agricultural and of the citrus experimental stations. He had become professor emeritus at the time of his death.

WEBER, vā'bĕr, **Albrecht,** German Indologist: b. Breslau, Germany, Feb. 17, 1825; d. Berlin, Nov. 30, 1901. He graduated from the University of Breslau in 1845, and in 1856 he became professor of Sanskrit language and literature at the University of Berlin, a post he held until his death. Weber was one of the greatest scholars on India of the 19th century, his studies covering the language, religion, philosophy, and science, as well as the interrelationship of the Indian and Semitic cultural worlds. He was chief editor and contributor of *Indische Studien,* 18 vols. (1856–1898), a collection of critical studies of Sanskrit texts edited and annotated by him. His *Akademische Vorlesungen über Indische Literaturgeschichte* (1852) was translated into French and English and is still one of the most authoritative publications on the subject.

WEBER, Ernst Heinrich, German physiologist and anatomist: b. Wittenberg, Germany, June 24, 1795; d. Leipzig, Jan. 26, 1878. He was educated in Wittenberg and Leipzig, and appointed professor of comparative anatomy there in 1818, of human anatomy in 1821, and of physiology in 1840. He originated the formula known as Weber's Law (q.v.) and a special compass to measure the intensity of the sense of touch. All his research works were collected in the *Annotationes anatomicae et physiologicae: programmata collecta* (1851).

WEBER, Georg, German historian: b. Bergzabern, Rhenisch Palatinate, Feb. 10, 1808; d. near Heidelberg, Aug. 10, 1888. He spent his life teaching at Heidelberg, first as a tutor, later as head master and from 1848 director of the local high school. He wrote three histories of the world which were very popular at the time: *Das Lehrbuch der Weltgeschichte* (1846, reedited in 23rd ed. by Baldamus, 1921–1929); *Weltgeschichte in Übersichtlicher Darstellung* (1851); and *Allgemeine Weltgeschichte mit besonderer Berücksichtigung des Geistes- und Kulturlebens der Völker,* 15 vols. (1857–1880; 3rd ed., vols. 1-4, 1919–1922).

WEBER, wĕb'ĕr, **Joseph,** American comedian and theatrical manager: b. New York, N. Y., Aug. 11, 1867; d. Los Angeles, May 10, 1942. He started his career at a very early age appearing with Lew Fields in juvenile "Dutch" sketches at small variety theaters. The two formed in 1885 a company of their own, which lasted until 1894; their plays, interspersed with dialect jokes and slapstick antics, became extremely popular. From 1895 to 1904 Weber and Fields owned and managed the Broadway Music Hall, where they continued to produce and act burlesque comedies and presented some of the music-hall stars of the day. *Helter-Skelter, Hurly-Burly,* and *Higgledy Piggledy* are the titles of some of their productions. They quarreled and separated in 1904, but in 1912 they resumed their partnership in vaudeville and revues; Weber later retired from the stage. See also Fields, Lewis Maurice.

WEBER, Baron **Karl Maria Friedrich Ernst von,** German composer, opera conductor, and pianist: b. Eutin, Holstein, Germany, Dec. 18, 1786; d. London, England, June 5, 1826. He was a pupil of J. P. Heuschkel of Hildburghausen, attaining great skill as a pianoforte virtuoso and much proficiency in the technique of composition; and continued his studies with Michael Haydn at Salzburg, and at Munich with Kalcher (harmony and composition) and Valesi (singing). His opera *Das Waldmädchen* (1800) was produced with but moderate success at Freiberg, though more fortunate at Chemnitz and (in 1805) at Vienna. A second opera, *Peter Schmoll und seine Nachbarn,* first presented at Augsburg (1803) met with no particular approval. Early in 1803 he went to Vienna, and there that curious genius the Abbé Vogler was for a year his instructor. By Vogler's aid, he secured the post of *kapellmeister* of the opera at Breslau (1804). He displayed great ability as an organizer and director, but resigned in 1806, and became musical

director to Prince Eugene of Würtemberg at Karlsruhe, Silesia. In 1807 he entered the service of Duke Louis of Würtemberg at Stuttgart as private secretary, and in 1808–10 was working on his first large opera, 'Silvana,' the libretto of which was to a large extent based on that of his earlier 'Waldmädchen.' He was falsely charged with fraud, and despite all lack of evidence against him, was perpetually banished from Würtemberg 26 Feb 1810. Then he went to Mannheim, where his first symphony was most favorably received, and his piano-playing was also very successful; and thence to Darmstadt, where he once more became a pupil of Volger. His comic operetta, 'Abu Hassan,' was completed in 1810 and given at Munich, and 'Silvana,' with additions, gained adequate recognition at Berlin in 1812. It was not, however, until 1813 that Weber held an important appointment; in that year he was made kapellmeister of the Prague opera, and there proved himself the first of the Great German musicians to be conspicuous also as a conductor. His administration of marked success was brought to a close by his giving it up in 1816. His chief compositions of this period were settings of Körner's songs, and the cantata 'Kampf und Sieg,' founded on the battle of Waterloo. In 1816 he went to Dresden, where previously Italian opera had held undisputed sway, to organize the new venture of German opera; and soon he had attained, except among a few partisans, an unqualified victory. The appointment was confirmed for life, and he was frequently summoned to direct the music of the chapel royal. He became widely known with the presentation of his opera, 'Der Freischütz,' at Berlin, 18 June 1821, which was quickly echoed elsewhere, being simultaneously given in London in three different places. Few operatic works, it is said, have equaled it in immediate triumph. 'Euryanthe' did not meet similar approval at Vienna (1823), though appreciation was duly encountered in Dresden, Leipzig and Berlin. On the commission of Charles Kemble of Covent Garden, London, he wrote 'Oberon' to an English libretto by J. R. Planché, himself learning English to be able to work to better effect. He conducted the first 12 performances, and after a reception which almost surpassed that of the 'Freischütz,' played at numerous concerts. With the 'Freischütz,' which struck a distinctively national note, Weber became the founder of what is known as the romantic school of German opera. He has been claimed as a predecessor of Wagner in adapting his music to the dramatic requirements, and the use of leading motives. In his operatic works he apparently preferred legendary and supernatural elements, which he could make musically effective. Though his operas are the best known of his writings, he did musicianly and even brilliant work in the direction of Lieder and pianoforte compositions. Consult Jähns, 'C. M. von Weber: Eine Lebensskizze' (1873); the biographies by Rau (1865); Benedict (1881); Reissmann (1882); Gehrmann (1899), and his son Max Maria von Weber (Leipzig, new ed., 1912); also Benedict, 'Musiciens du Temps Passé' (1893), and the article by Spitta in Grove's 'Dictionary' (Vol. IV, 1889).

WEBER, Wilhelm Eduard, German physicist, brother of E. H. Weber (q.v.): b. Wittenberg, 24 Oct. 1804; d. Göttingen, 23 June 1891. He was educated at Halle, was professor of physics at Göttingen in 1831–37 and occupied that chair at Leipzig in 1842–49, after which he resumed his chair at Göttingen. He was associated with his brothers and with Gauss in various publications concerning physics, and made valuable researches in the fields of electricity and magnetism. He also published a series of essays, 'Elektrodynamische Massbestimmungen' (1846–67). Consult Heinrich Weber, 'Wilhelm Weber' (1893).

WEBER, wē'bėr, a river of Utah, whose headwaters are on the west slope of the Uinta Mountains. It flows northwest through fertile lands and through a series of cañons; and after a course of nearly 200 miles it enters Great Salt Lake. The famous Weber Cañon is the gorge made by this river where it breaks through the Wasatch Mountains. The Union Pacific Railroad passes through this gorge. The descent in places is most rapid, and the consequent water-power is extensive. At Ogden, the mean volume of water is about 2,000 cubic feet a second. The Weber is much used for irrigation. The river has built up at Ogden a large delta which extends into ancient Lake Bonneville.

WEBER'S LAW. In the 30's of the last century E. H. Weber (q.v.) made the discovery that a subject who could barely distinguish between lifted weights of 29 and of 30 ounces could also barely distinguish between weights of 29 and 30 drachms. Similar results were obtained in the case of cutaneous pressure and in the visual measurement of short lines. That is, it appeared in each case that the just noticeable increment of a stimulus was not a constant, but bore instead a constant ratio to the strength of the stimulus itself. This generalization, which is Weber's law, is a precise statement of the fact which is familiar to us in such cases as that of the ticking of a watch, quite inaudible on the noisy street though it may be very loud in the silence of the bedroom. The ratio of the barely observable increment or difference limen to the stimulus is dependent on the kind of stimulus used. For pressures on the tip of the finger it is nearly 0.05, for noise loudnesses it is about 0.33, for lifted weights, 0.033, and for brightness, 0.01. Weber's law is only an approximation at best. It is badly in error for very great or very small stimuli; even for those of moderate intensity it presupposes a complete adaptation of the percipient organ. It is not in general valid for other attributes of sense than intensity, although it seems to hold good for visual extension. In the pitch of tones, for instance, the just noticeable increment is about .75 vibrations per second for a considerable range of the scale. In so far as we are able to equate easily noticeable intervals in different parts of an intensity scale, it appears that these obey the same law as just noticeable intervals; that equal-appearing intervals between stimuli are proportional to the intensity of the stimuli evoking the lower terms of the intervals, and are made up of an equal number of just noticeable intervals. This assemblage of facts was raised by G. T. Fechner (q.v.) to the dignity of a necessary law expressing the relationship of mind and matter. He represented the fact that a constant increment of a sensation is

produced by a fixed proportional change in the stimulus by the formula $s_1 - s_2 = f\left(\frac{i_1}{i_2}\right)$, where i_2 is the stimulus inducing the sensation s_1. We obtain from this at once

$$s_1 - s_2 = f\left(e^{\log \frac{i_1}{i_2}}\right) = f,$$

$$\left(e^{\log i_1 - \log i_2}\right) = \phi, \ (\log i_1 - \log i_2).$$

As i_1 depends only on s_1, and i_2 depends only on s_2 in the same way, we get $s_1 = \phi$, $(\log i_1 - c)$, and $s_2 = {}_k\phi$ $(\log i_2 - c)$, where c is the value of $\log i_k$ for $s_1 = 0$. Therefore ϕ $(\log i_1 - c) - \phi$ $(\log i_2 - c) = \phi$ $(\log i_1 - \log i_2)$, so that ϕ satisfies the functional equation ϕ $(x) - \phi$ $(y) = \phi$ $(x - y)$.

Differentiating with respect to x, ϕ^1 $(x) = \phi^1$ $(x - y)$, which is only possible for all values of x and y if ϕ^1 (x) is some constant such as K_1, or if ϕ (x) is of the form $K_1 x + K_2$. It is easily seen that $K_2 = 0$. We thus get $s_1 - s_2 = K_1 (\log i_1 - \log i_2)$. By the proper choice of units this becomes $s_1 = K \log i_1$. Fechner's law is, then, that the sensation varies as the logarithm of the stimulus.

There are several serious objections to Fechner's treatment of the law. In the first place, it is more than probable that the basis of the phenomena observed lies rather in the make-up of the nervous system than in the transition from the physical phenomena of the nervous system to the percipient mind. Even Wundt's explanation of the facts by apperception is vitiated by the appearance of the same logarithmic formula in the reactions of the nervous system of a decerebrized frog. Secondly, what is being determined in the mind of the subject of an experiment on discrimination is not the difference between two mental states, but the *awareness* of that difference, which is altogether another thing. The existence of limina is in itself enough to refute Fechner's opinion that it is actually the difference between two mental states which is reported, for things identical with the same thing are identical with one another, whereas a weight of 61 drachms is sensibly equal to the discriminable weights of 60 and 62 drachms. In the third place, while measurement of sensations is a conceivable thing, it is most assuredly not done directly, so that the whole interpretation of Fechner's law remains indeterminate until a thorough logical analysis is made of the processes involved in our actual measurement of the intensity of sensation.

The general types of method used in experiments and investigations on Weber's law are that of just noticeable differences, where two stimuli are gradually separated or approximated until their difference appears or disappears; that of average error, in which the average error of the observer in selecting a variable stimulus equal to a given fixed stimulus is taken as the index of the just noticeable difference or limen; that of equivalents, which differs from that of average error only in that the stimuli are applied simultaneously to different parts of the body rather than successively to the same part; that of mean gradations, in which a supraliminal interval is bisected; and that of right and wrong cases, in which the mean position of the initial stimulus limen or the difference limen is determined by ascertaining throughout a series of trials for each intensity of stimulus or magnitude of stimulus difference the proportion of cases in which its presence or absence is rightly judged. (See LIMINA; PSYCHOPHYSICS). Consult Delboeuf, J. R. L., 'Examen critique de la loi psychophysique' (Paris 1883); Fechner, G. T., 'Elemente der Psychophysik' (Leipzig 1889); Fullertan and Cattell, 'On the Perception of Small Differences' (Philadelphia 1892); Külpe, O., 'Outlines of Psychology' (tr. WEBSTER, Arthur Gordon, American physicist: b. Brookline, Mass., 28 Nov. 1863; d. Worcester, Mass., 15 May 1923. He was graduated at Harvard University in 1885, later studied at Paris and Stockholm, and in 1890 took his Ph.D., at Berlin. He received in 1895 the Thompson prize, Paris, of 5,000 francs for experimental research on the period of electrical oscillation. He was assistant professor of physics at Harvard in 1892–1900; and from 1900 he was professor and director of physics at Clark University. He was appointed to the Naval Consulting Board in 1915; and to the National Research Council in 1917. He was an authority on sound and the inventor of several instruments of value in this connection. Author of 'A Mathematical Treatise on the Theory of Electricity and Magnetism' (1897); 'Dynamics of Particles of Rigid, Elastic and Fluid Bodies' (1903); 'Harrison Lectures on Sound, University of Pennsylvania' (1911), etc.

WEBSTER, Daniel, American statesman: b. Salisbury (now Franklin), N. H., 18 Jan. 1782; d. Marshfield, Mass., 24 Oct. 1852. He was the son of a New Hampshire judge and farmer and brother to a large family of boys and girls, all of whom worked and sacrificed in favor of Daniel whose health was apparently not robust. After rather meagre preparation he attended Exeter Academy a year. Thence he went to Dartmouth College where he was graduated in 1801 with good if not distinguished standing. He loved to study English and classical literature; he liked self-indulgence; and he was already an orator for Fourth of July occasions. More than once he had shown a disregard to that rigid honesty in little money matters which was later to become such a distressing trait of his character.

From Dartmouth to the farm of the hard-pressed father was not a congenial move for a young man so filled with ambition to play a rôle in the great world outside; but the road to the goal he vaguely set himself was not easy to find. He studied law a while in the office of a friendly lawyer nearby but inclined rather to general reading and to fishing than to rigid self-discipline. Next he turned to teaching school in the town of Fryeburg, Me., in the hope of winning ready money, so much needed in the Webster family, now that another son was sent to Dartmouth. After one session at Fryeburg, he returned to his native town of Salisbury and resumed the study of law in earnest. Ezekiel

the brother who had been at Dartmouth, now took a school in Boston and Daniel followed him to the New England metropolis. Here he studied law under the distinguished Christopher Gore, a little later governor of Massachusetts, and always a prince of the old New England culture. Gore was certainly not of the type of Ezekiel Webster, the farmer judge of New Hampshire, but he was the bitter enemy of that "Mr. Jefferson, the atheist Virginian" who had broken the power forever of the Federalists of New England. Webster absorbed the politics of localism and provincial superiority which a little later threatened to ruin a great career.

Admitted to the Boston bar on the recommendation of Gore himself in March 1805, Webster, a little past his 23d birthday, returned to his native State and there, in the town of Boscawen, began the practice of his profession. He was quickly successful; but realizing that a larger sphere for the display of his talents was necessary, he removed to the important commercial town of Portsmouth in the year 1807.

Here he came into touch with real New England, with men who went down to the sea in ships and brought back rich harvests from the banks of Newfoundland, from the marts of Europe and even from the strange cities of China. He met and competed with great lawyers, like Jeremiah Mason and William Plumer, and he learned to think in generous figures, not in the niggardly shillings and pence of his boyhood. For five years he learned from these men and from renewed study of the great British law authorities. Webster received or gave himself a broad and deep training, whereas his great rival in life, Henry Clay, had little or no training. Moreover he earned large fees in those exasperating years of non-importation acts and embargoes, procured for himself a good town house and went back to his native countryside and married Miss Grace Fletcher, the daughter of the minister at Hopkinton. He spoke against the government on every suitable occasion; learned to write great orations and to move large audiences; and shaped barbed resolutions against James Madison and his inconsiderate Virginians who monopolized all the great offices of the nation. He learned rather better than history has recorded the language of resistance and secession. How could he do otherwise in a community whose people were delighted with young William Cullen Bryant's first poem, "The Embargo." Thus trained, deeply resentful at the policy of the national government in going to war with England a second time and ambitious to meet the enemy face to face, he became a candidate for a seat in the National House of Representatives, was elected on a most flattering vote and took his seat in May 1813.

From 1813 to 1817 Webster served New Hampshire in the House of Representatives. He opposed the Madison administration at every turn as every good New Englander must do. His protests against the conduct of the war, against Federal interference with New England trade and against the conscription of soldiers to fight the war were all animated by a warm and even impassioned sectionalism that reminded one of the Massachusetts secessionist, Josiah Quincy, just retired in disgust from a government which seemed destined to remain in the hands of slave-holding Southerners and ignorant frontiersmen. If Webster was more discreet, it was probably because the exasperation of Southern leadership was not quite so disturbing to him. But Webster was already a great lawyer and very much of his time, as well as the best of his talent, was during these four years spent in the Federal courts, both at Boston and in Washington where Chief Justice Marshal took pains to express his hearty admiration of a fellow partisan who could distress Mr. Madison. When the second term in the house was about to expire, Webster declined to offer himself in New Hampshire for re-election and removed to Boston, having first thought of making New York his home — for there, he said, the great decisions of the near future would be made.

In Boston, he quickly received that recognition and adulation which seems to have become necessary to his happiness and success. From 1816 to 1823, he again practised his profession with eminent success. His income from fees increased, in spite of the lean years that followed the close of the war with England, from $2,000 to $20,000 a year. The wealthy and the distinguished yielded to the son of the New Hampshire frontiersman who lived in the handsome house on Somerset street and deported himself with all the dignity of a Cabot or a Dana. With wealth abounding and social distinction undisputed, even in Boston, Webster now gave himself to the delivery of a series of commemorative orations that made his name known wherever New Englanders dwelt or New England newspapers were read. The Plymouth (1820) and the Bunker Hill (1826) addresses were the best of these, although others, like that on the Character of Washington and on the Landing at Plymouth, were reprinted in every important eastern paper. It was the day of oratory. There were few scholars and the clergy were fast losing their former mastery of the popular imagination. Public men must be learned, or appear to be so, and they must on occasion display their learning and their fine phrases in well-rounded periods. Of all Americans who essayed the rôle of classic oratory on the frontier soil of America Webster was the foremost. He had a remarkable personality; his voice and manner were both imposing and winning; and he had a memory that always served him admirably. When Webster spoke men laid down their tools or stopped their plows in the field and went to hear him. They would gladly stand in great outdoor audiences or crowd themselves into Faneuil Hall for hours at a time on hot days in order to look upon his majestic form or follow his moving imagery. Thus, before the great struggle in the country about the tariff and the powers of the Federal government, Webster was prepared as few men ever had been prepared for attack or defense.

It was an easy matter, then, in 1822 for him to procure once more a seat in the national House of Representatives. He represented Boston. He was a strict sectionalist. In 1814, when he spoke for a New Hampshire constituency, he had threatened to resist the national authority and he sympathized fully with those recalcitrant governors and judges of New England who refused to furnish troops to the national administration or who declared Federal laws inoperative in States that did not approve Federal policy. In 1820 Webster was so much

opposed to the tariff laws of the Union that he threatened secession in a notable speech. When he appeared in his place in the national legislature late in 1823 he was ready for a great struggle.

Henry Clay was the leader of the House of Representatives at that time and he was pressing with all his energies the tariff and internal improvement bills which together he christened the "American System." Webster opposed Clay in the best speech that had ever been made in Congress on the subject of the tariff. It is known as his free trade speech. It was delivered in 1824. The arguments which he then arranged and massed in consummate style have never been answered. But New England was changing. He was a New Englander. In 1825 a New Englander, John Quincy Adams, became President and half of New England changed its investments from shipping to manufactures. Before 1828 Webster was himself in a quandary. He must change his attitude or cease to play a part in public life. His position was exactly parallel to that of Calhoun who had been a strenuous protectionist but whose constituents now became free traders. Calhoun abandoned protection which South Carolina would no longer endure; and Webster abandoned free trade which Massachusetts then and henceforth condemned. Calhoun was the Vice-President and very ambitious to be President. Webster was elected to the Senate in 1827 and he too soon became possessed with the ambition to rise to the presidency.

When Webster took his seat in the Senate, Henry Clay was the Secretary of State and the director of the policy of the party with which Webster must work, the incipient Whig party, the party of protection to American industries, of wide-flung schemes of internal improvements and of expanding the powers of the national government. The New Englander quickly fell into line. In 1828 he made his first important speech in favor of the "American System," so ably condemned four years before, and Calhoun prepared to thwart that very tariff policy which he had done so much to set up in 1816. Nullification was about to be tried and Webster from opposing the national power, as he had done all his life, now prepared to champion that cause. The greatest speech of his life was delivered in February of 1830 when western influences in Congress opposed to the leadership of Henry Clay were being aligned with the southern influences and interests voiced by Calhoun and Robert Young Hayne. These leaders of the three great sections of the country were compelled to work out a national policy which it was hoped that a majority of the people might support.

Thomas H. Benton had pressed for six years his bill for a freer distribution of the public lands in the hope of building up the West at the expense of the East. Webster opposed the Benton plan. The Southerners were divided; but, after long and doubtful negotiations, they had made up their minds to support the western claims in exchange for support of their free trade policy. Jackson was made President upon this combination. Webster did not like the combination. It meant disaster for New England. But Jackson did not like the power and influence of Calhoun in the combination which lay behind his own presidency. When, therefore, Calhoun prepared to launch his nullification program, expecting that Jackson would remain quiescent, there were signs that the President would revolt. It was the primary interest of New England that Jackson and Calhoun should break, that the West and the South should not continue their coalition, or alliance.

Soloman Foot of Connecticut made the first move in his resolutions of early January 1830, in which it was proposed to withdraw the public lands from sale. Benton was quick to denounce the resolution as indicative of the selfish and provincial policy of New England. The Southerners came to the support of Benton. The great debate was begun. Hayne of South Carolina made an elaborate attack upon New England, which roused Webster's ire; but Hayne also publicly announced that the South would support the West in its land program which made him uneasy. To this Hayne also added a long and thoughtful argument against the growing powers of the Federal government. The nation was only a confederation. It was only what the Constitution provided, but not a power of original jurisdiction over the people. Webster replied. He defended New England; said nothing about the subject of the public lands; and closed in a magnificent appeal to the people of the country on behalf of the government as a government of real powers. "The Union, one and inseparable, now and forever." It was strange doctrine from New England. But New England had changed its interest and its attitude. Chief Justice Marshall and the Federal courts had long been working to the same end with New England and the East as a whole. Webster stirred in men a devotion, as yet but half-aroused anywhere, to the ideal of a great national government supreme over all States, all sections and all American citizens. It was to be one of the classics of American oratory. There can be no doubt that it proved to be a powerful influence during the next 30 years. No President, duly cognizant of the meaning of his own office, could remain deaf to an appeal like Webster's. Jackson made it known in April following that he agreed with his New England opponent. When Calhoun's friends would have had him talk of States' rights at a Jefferson dinner, he boldly announced that he drank to the Union, "it shall be preserved." If that were so the alliance of South and West was dissolved and Daniel Webster had done much to dissolve it.

From 1830 to 1850 Webster remained almost uninterruptedly in the Senate. He supported the United States Bank in the long war it made upon the President and the nation he talked of in the great oration. He played a great part in the campaign of 1840 which resulted in the election of William Henry Harrison to the presidency and was under Secretary of State. When Vice-President Tyler succeeded in May 1841 to the office made vacant by the death of Harrison and when Henry Clay undertook to manage Tyler as a modern boss generally manages a governor of his own nomination, Webster revolted against the counsels of his chief, Clay, and retained his seat in the Tyler Cabinet. As Secretary of State under Tyler, Webster negotiated a treaty with the British Minister, Lord Ashburton, which was long known by the names of the two negotiators.

But Webster retired in May 1843. Already

the nomination and election of Henry Clay seemed to be foregone conclusions. Webster, in spite of Clay's dislike of his insubordination, gave earnest support to the Clay ambition. Clay was again defeated and Webster himself now expected that his turn for the leadership of the Whig party had come. He returned to the Senate in 1845 where he renewed his opposition to the annexation of Texas in its final stages. When the war with Mexico began he was, as usual, in full sympathy with the heated and unalterable opposition of his section. But he was too much of a candidate for the presidency to voice his views very strongly. Yet he failed of the Whig nomination in 1848. A successful general and a great slave-holder, Zachary Taylor, received the nomination as a result of Abolitionist opposition to Webster and Clay. Webster declared that it was an improper and unworthy nomination; and both Webster and Clay declined to give public support. Yet Taylor was elected.

Taylor, the slave-holder, urged the admission of California as a free State. As a result civil war between the North and the South seemed imminent. Webster was still in the Senate. Calhoun was again a member in 1845, after a retirement that had been designed to be final. Clay was returned to the Senate at this critical juncture to aid in reconciling the hostile sections of the country, reconcile interests that were in violent conflict. Since Webster, Calhoun and Clay so well represented the three sections — the East, the South and the West — any agreement satisfactory to them was likely to be satisfactory to the country. Clay took the lead, as he had done all his life. Calhoun placed himself in direct and bitter opposition. The South would never consent to the admission of another free State south of the line of 36° 30′, extended to the Pacific.

Unexpectedly President Taylor maintained the position that California must be admitted as a free State. A deadlock ensued. From the opening of Congress in December 1849 till the first of March 1850 it seemed that a disruption of the Union must be the outcome. Under these circumstances Clay arranged his last great compromise. It was prepared early in January. Private meetings of senators and representatives were arranged. Old enemies sat down to dinners together and with Clay. Newspaper editors were consulted and combinations made. When Clay at last made his appeal to Congress and the country, he had Webster's consent to follow him with a similar appeal. But President Taylor would have nothing to do with the compromise. Webster and Clay had both said he was an unfit man to be President. Moreover the Southern leaders challenged Taylor, and a challenge of the President as to his powers and his independence has almost invariably been fatal to the challenging party. Taylor would send the United States army into any territory where the Southerners refused to recognize the authority of the United States. That meant immediate war.

Webster had been a nationalist since 1830. He was not in sympathy with the Administration of his own party, which was supported by the Abolitionists. He was by nature a conservative, one who liked to have great social changes made slowly or not at all. He represented the manufacturers and the stable business element of New England and not what would be called the democracy of the North. He made the only decision that he could have made. It was given to the world on 7 March 1850 in a great and eloquent appeal to the public sentiment of the country, North and South, against the disruption of the Union. This decision of Webster broke the deadlock; it ranged his great followers alongside that of Clay. The country rallied to the two old chieftains. The President resisted till 9 July, when death removed him from the scene. Vice-President Fillmore, a friend of Webster and Clay, succeeded and the country breathed freely. In every large town there was a holiday, and big guns announced the passage of the compromise. It had been Webster's decision in March that produced the result. Not even Taylor's military stubbornness could long have withstood the tide of popular demand for a settlement.

Webster entered President Fillmore's Cabinet as Secretary of State and served the ideals of the country well, particularly in the publication of the Hulsemann letter, in which American sympathy for democratic uprisings everywhere was vigorously expressed. But he was denounced for his 7th of March speech most unmercifully. His name was anathematized in 'Ichabod,' one of the widely read poems of Whittier. But the country as a whole did not think less of him, only the people did not demand him for President. When the Whig national convention met in Baltimore, June 1852, to nominate a candidate for the presidency, Webster was the logical candidate. According to all the rules of regular political procedure, the great New England statesman should have received the nomination. But the convention, under the influence of Thurlow Weed and William H. Seward, preferred another military "hero." General Scott was nominated. Webster, broken hearted, went home to Northfield. There he made known his wish that his friends would vote for the Democratic candidate, Franklin Pierce. It was a trying ordeal, the public abandonment of his party. He died before the election. Like so many other great leaders, he died despairing of the republic.

WILLIAM E. DODD,
Professor of American History, University of Chicago.

WEBSTER, Ebenezer, American patriot, father of Daniel Webster (q.v.): b. Kingston, N. H., 1739; d. Franklin, N. H., 1806. In his youth he served under General Amherst in the "old French war," and in 1761 was one of the original settlers of that part of the town of

Salisbury now known as Franklin. He combined, as was common at the time, the occupations of farmer and innkeeper; took an active part in public affairs; and at the outbreak of the American Revolution led the Salisbury militia to Cambridge, Mass. Subsequently he fought at White Plains and Bennington and served in other campaigns until the close of the war, by which time he had attained the rank of colonel of militia. Webster served at various times in both houses of the New Hampshire legislature, and from 1791 until his death was a lay judge of the county court of common pleas.

WEBSTER, H(arold) T(ucker), American cartoonist: b. Parkersburg, W. Va., Sept. 21, 1885; d. Stamford, Conn., Sept. 22, 1952. At the age of seven he began to draw, and when he was about 12 he sold his first cartoon. After studying art in Chicago for a short time, he went to work for the Denver *Post* but soon returned to Chicago to work for the *Daily News* (1903–1905) and the *Inter-Ocean* (1905–1908). Later, from 1908 to 1910, he worked on the Cincinnati *Post*. After a trip around the world in 1911, he settled in New York and drew cartoons for the Associated Newspapers, going to work for the New York *Tribune* in 1919 and the New York *World* in 1923. In 1931 he began to draw for the New York *Herald Tribune*, and eventually his work was syndicated in over 120 North American newspapers.

In thousands of cartoons, Webster commented with acute insight on the American character and social scene. Among his popular cartoon series were "The Timid Soul," which with Caspar Milquetoast added a beloved figure to the national mythology; "Life's Darkest Moment" and "The Thrill That Comes Once in a Lifetime," which nostalgically evoked his boyhood in Wisconsin; "The Unseen Audience," satirizing radio and television, which earned him a Peabody Award in 1950; "They Don't Speak Our Language"; "Poker Portraits"; "Bridge"; and "How to Torture Your Wife (Husband)." He published collections of cartoons in *Our Boyhood Thrills and Other Cartoons* (1915); *Boys and Folks* (1917); *The Timid Soul* (1931); and *Webster Unabridged* (1945).

WEBSTER, Henry Kitchell, American novelist: b. Evanston, Ill., Sept. 7, 1875; d. there, Dec. 8, 1932. After being graduated from Hamilton College in 1897, he taught rhetoric for a year at Union College and then returned to Evanston to devote himself entirely to writing. Among his published works are *The Whispering Man* (1908); *The Ghost Girl* (1913); *The Butterfly* (1914); *The Real Adventure* (1916); *The Painted Scene* (1916); *The Thoroughbred* (1917); *An American Family* (1918); *Mary Wollaston* (1920); *Real Life* (1921); *The Innocents* (1924); and *The Sealed Trunk* (1929).

WEBSTER, Herman Arthur, American painter and etcher: b. New York, N. Y., April 6, 1878. After being graduated from Yale University in 1900, he went to Paris, where he studied art at the Académie Jullian under Jean Paul Laurens. Although he attained some reputation as a painter, he became best known as an etcher, particularly of scenes in out-of-the-way French towns. His work is represented in the Luxembourg, Paris; the Victoria and Albert Museum, London; the Library of Congress, Washington; the Boston Museum of Fine Arts; and the Art Institute, Chicago.

WEBSTER, Jean (in full ALICE JANE CHANDLER), American writer: b. Fredonia, N. Y., July 24, 1876; d. New York, N. Y., June 11, 1916. She was educated at the Lady Jane Grey School, Binghamton, N. Y., and at Vassar College, from which she received a B.A. degree in 1901. After spending a few years in Italy and traveling around the world (1906–1907), she made her home in New York. In 1915 she married Glenn Ford McKinney, a New York lawyer. Her interest in underprivileged children led her to write her most popular novel, *Daddy Long-Legs* (1912), which she successfully dramatized in 1914. A sequel, *Dear Enemy*, appeared in 1914. She was also the author of *When Patty Went to College* (1903); *The Wheat Princess* (1905); *Jerry Junior* (1907); *The Four Pools Mystery* (1908); *Much Ado About Peter;* and *Just Patty* (1911).

WEBSTER, John, English dramatist: b. about 1580; d. ?1625. Very little is known of his life, but he was probably born in London, where his father was a tailor, and he himself was a freeman of the Merchant Taylors' Company in 1604. In 1602 he began to write plays for the theater manager Philip Henslowe in collaboration with other dramatists, but he attained his full powers only when, between 1607 and 1612, he adopted independent authorship. He altered and wrote an introduction to *The Malcontent*, a play by John Marston, and was associated with Thomas Dekker in writing two vigorous prose comedies, *Westward Hoe* (produced 1604) and *Northward Hoe* (produced 1605). *The White Devil or Vittoria Corombona*, published in 1612, was his first independent work; it is now recognized as one of the best tragedies of the Jacobean period. *Appius and Virginia*, written soon afterward and published in 1654, was long attributed solely to Webster, but it was probably partly the work of Thomas Heywood. Webster's masterpiece was *The Duchess of Malfi*, which was first produced at the Blackfriars Theatre about 1614 and published in 1623. This great tragedy, which won enthusiastic praise from Charles Lamb and many later critics, was based on a Neapolitan story found in Matteo Bandello's *Novelle*. *The Devil's Law Case*, also published in 1623, appears to have been Webster's last play. Of other plays sometimes ascribed in part to Webster, only *A Cure for a Cuckold* (published in 1661) seems to contain any of his work. He also wrote prefatory verses to Heywood's *Apology for Actors* (1612) and collaborated with Heywood and Cyril Tourneur in writing *Three Elegies to the Memory of Prince Henry* (1612). In 1624 he wrote a pageant for the lord mayor of London. The best edition of Webster's works is that of Frank Laurence Lucas (4 vols., 1927).

Consult Gosse, E. W., *Seventeenth Century Studies* (London 1883); Swinburne, A. C., *Studies in Prose and Poetry* (London 1894); Ellis-Fermor, U. M., *The Jacobean Drama* (London 1936); Leech, Clifford, *John Webster: A Critical Study* (London 1951).

WEBSTER, Joseph Dana, American soldier and engineer: b. Hampton, N. H., Aug. 25, 1811; d. Chicago, Ill., March 12, 1876. After being graduated from Dartmouth College in 1832, he studied law and in 1835 entered government service as a civil engineer. Three years later he was

commissioned a second lieutenant of topographical engineers. He remained in the army, rising to the rank of captain, until 1854, when he resigned his commission and went to Chicago, where he obtained an interest in a firm manufacturing agricultural implements. As a member of the city sewage commission, he helped to solve the problems involved in constructing the Chicago sewage system, a project which involved raising the grade of a large part of the city. At the beginning of the Civil War he was charged with the construction of fortifications at Cairo, Ill. In 1862 he became colonel of the 1st Illinois Light Artillery, but shortly thereafter was appointed chief of staff to Gen. Ulysses S. Grant. Commissioned brigadier general as of November 1862, he was made military superintendent of the railroads in the area of Grant's operations. Subsequently he served as chief of staff for Gen. William T. Sherman, and retired from the army in 1865 with the rank of brevet major general of volunteers. Returning to Chicago, he served as assessor of internal revenue (1869–1872), assistant United States treasurer (1872–1875), and collector of revenue (1875–1876).

WEBSTER, Noah, American lexicographer and author: b. West Hartford, Conn., Oct. 16, 1758; d. New Haven, Conn., May 28, 1843. In 1774 he entered Yale College, but his studies were interrupted by the outbreak of the Revolutionary War, in which he served as a volunteer. After receiving his degree in 1778, he studied law and was admitted to the bar in Hartford in 1781. The unsettled state of the country prevented his obtaining a suitable opening in his profession, and for several years he taught school in various places. While at Goshen, N. Y., in 1782, he wrote an elementary spelling book, which he published in Hartford in the following year as part 1 of *A Grammatical Institute of the English Language.* Part 2, a grammar, appeared in 1784; and part 3, a reader, in 1785. The speller, known as *Webster's Spelling Book* or *Blue-Backed Speller,* was extremely popular in various editions for more than a century, and by 1890 more than 60 million copies had been printed; it had great influence in standardizing orthography and pronunciation in the United States. As an author, Webster was disturbed by the lack of federal or state copyright laws, and from 1782 to 1789 he devoted much of his time and energy to agitation for a uniform copyright law, which he came to believe could be achieved only through the establishment of a strong federal government. In 1785 he set forth his views in *Sketches of American Policy,* and two years later he published a pamphlet urging the adoption of the Constitution. In 1785–1786 he gave lectures on the English language in various cities, and these he published in 1789 as *Dissertations on the English Language.* These interests led to correspondence with Benjamin Franklin and to experiments with spelling reform. After an unsuccessful venture as editor of the *American Magazine* in New York in 1787–1788, Webster went to Hartford, where he practiced law until 1793. Returning to New York, he established two Federalist newspapers, a daily, the *Minerva* (later the *Commercial Advertiser*), and a semiweekly, the *Herald* (later the *Spectator*). He maintained his ownership of both papers until 1803, but he moved to Hartford in 1798 and thereafter devoted most of his time to writing. In 1806 he published his first lexicographical work, *A Compendious Dictionary of the English Language,* in which he included about 5,000 words not found in previous dictionaries. In 1812 he moved to Amherst, Mass., meanwhile continuing his research. He served as a member of the Massachusetts legislature in 1815 and 1819, and as trustee (1816–1821) and president (1820–1821) of Amherst Academy, and he helped to found Amherst College. In 1822 he returned to New Haven and resided there until his death.

Webster's great work was *An American Dictionary of the English Language,* the fruit of more than 20 years of study and research. In 1824, when the work was nearly completed, he went to France and England to obtain additional material, and he finished his dictionary during an eight months' residence in Cambridge, returning to the United States in 1825. A two-volume edition was published in 1828, and a revised and enlarged two-volume edition in 1840. Webster ranks as the greatest of American lexicographers. He originated most of the accepted dictionary forms and laid the groundwork for the modern comprehensive lexicon. Although he made some errors in word derivations, his definitions were excellent and his scholarship in general was of a high order. In 1843 the rights to his dictionary were sold to the firm of G. & C. Merriam, Springfield, Mass., which has continued to publish it in various editions, the latest unabridged version being *Webster's New International Dictionary of the English Language* (2d ed.).

Webster was a man of wide interests, and he published works in many fields. In addition to those previously mentioned, he was the author of a pamphlet, *The Revolution in France* (1794); 10 essays under the signature Curtius in favor of Jay's Treaty (1795); *A Brief History of Epidemic and Pestilential Diseases* (2 vols., 1799), which he wrote after an outbreak of yellow fever and which became a standard work; *Ten Letters to Dr. Joseph Priestley* (1800); *Historical Notices of the Origin and State of Banking Institutions and Insurance Offices* (1802); *A Philosophical and Practical Grammar of the English Language* (1807); *Origin, History, and the Connection of the Languages of Western Asia and of Europe* (1807); *History of the United States* (1832), long popular as a textbook; and a revision of the *Authorized Version of the Bible* (1833). *Experiments Respecting Dew* (1809) was a pioneer scientific work. In addition, Webster edited John Winthrop's *Journal* (1790).

Consult Scudder, H. E., *Noah Webster* (Boston 1881); Shoemaker, E. C., *Noah Webster: Pioneer of Learning* (New York 1936); Warfel, H. R., *Noah Webster: Schoolmaster to America* (New York 1936); Proudfit, I. B., *Noah Webster* (New York 1942).

WEBSTER, Pelatiah, American publicist: b. Lebanon, Conn., Nov. 24, 1726; d. Philadelphia, Pa., Sept. 2, 1795. After being graduated from Yale College in 1746, he studied theology and from 1749 to 1755 was a Congregational minister in various towns. Settling in Philadelphia, he became a merchant and amassed a considerable fortune. Webster was a student of the problems of currency, finance, government, and national resources, and during the Revolutionary War he aided the American cause with his purse and pen. He was imprisoned by the British at Newport in 1777 and for several months at Philadelphia in 1778, and his property was confiscated. He wrote *Essays on Free Trade and Finance* (1785); *A Dissertation on the Political Union and Con-*

stitution of the Thirteen United States of North America (1783).

WEBSTER, Richard Everard, 1st Viscount Alverstone, British jurist: b. Dec. 22, 1842; d. Cranleigh, Surrey, Dec. 15, 1915. Educated at Cambridge University, he was called to the bar in 1868. The Conservative government selected him as attorney general in June 1885, and the next month he secured election to Parliament, a necessary prerequisite to occupying the post. He was attorney general until 1892, and again from 1895 till 1900. He was representative of Great Britain in the Bering Sea Controversy (q.v.) in 1893 and in the Venezuelan Boundary Dispute (q.v.) in 1898. Knighted in 1885, he was raised to the peerage as Baron Alverstone in 1900 on appointment to the mastership of the rolls. On becoming lord chief justice in October 1900, he received a viscountcy. During 1903, he served as a member of the Alaska Boundary Commission (q.v.). He retired in 1913.

WEBSTER, town, Massachusetts, in Worcester County, on the French River 16 miles southwest of Worcester; it is served by the New York, New Haven and Hartford, and the Boston and Albany railroads. Industries include the manufacture of textiles, paper, and shoes. The town was set off from Dudley and Oxford in 1832. Pop. (1950) 13,194.

WEBSTER-ASHBURTON TREATY, The, in United States history, a treaty signed in Washington, D.C., in August 1842. The chief negotiators were Daniel Webster and Lord Alexander Baring Ashburton (qq.v.). It settled the boundary between the state of Maine and Canada. Seven twelfths of the disputed ground was assigned to the United States; Canada's share included heights commanding the St. Lawrence which an earlier award by the king of the Netherlands had assigned to the United States. Other provisions related to suppression of the African slave trade and the mutual extradition of criminals. See United States—*38. United States Diplomacy* (Oregon Question).

WEBSTER CITY, city, Iowa, Hamilton County seat; altitude 1,040 feet; on Boone River; 71 miles northwest of Des Moines; served by the Fort Dodge, Des Moines and Southern; the Chicago and Northwestern; and the Illinois Central railroads. Industries include the manufacture of washing machines, electric football and basketball scoreboards, and farm machinery. The town was founded in 1850 by Wilson C. Brewer; government is the council-manager form. Pop. (1950) 7,611.

WEBSTER GROVES, city, Missouri, in St. Louis County; on southwestern outskirts of St. Louis, of which it is a residential suburb; served by the Missouri Pacific and St. Louis-San Francisco railroads. Webster College (part of St. Louis University, for women, founded 1915), and Eden Theological Seminary (Protestant) are located there. Webster Groves became a city in 1914, and has the commission form of government. Pop. (1950) 23,390.

WEBWORMS, various species of caterpillars or lepidopterous larvae, so named because of their habit of spinning webs of silk, enclosing leaves upon which they feed, and also serving as a shelter. As a rule neither the web-spinning nor the social habit is so highly developed as in the tent-caterpillars (q.v.), but there is no sharp distinction in the application of the two names. The species of caterpillars exhibiting such habits are quite numerous and belong to a number of genera and families of moths (q.v.). Some of them are of considerable economic importance. The fall webworm is the larva of the small white moth (*Hyphantria cunea*). As soon as they leave the egg all of the larvae hatching from a mass spin a common web enclosing several leaves. After these are eaten the caterpillars wander farther and farther in search of food, sometimes destroying the entire foliage of a tree, but always returning to the shelter of the nest to rest when not feeding. Typical of a large and quite distinct group of caterpillars is the garden webworm (*Loxostege similalis*), which is a small, nearly naked caterpillar that feeds in company on all kinds of garden vegetables. Some of the related species form large colonies. The root webworms are caterpillars of the little roll-wing moths. *Crambus vulvigagellus* is a common species, which spins a web about the stalks and roots of grass and corn to which it is sometimes very destructive. The true tent-caterpillars belong to the genus *Clisiocampa* and family Bombycidae.

WEDDELL, wĕd'ĕl, **SEA,** Antarctica, wide arm of the South Atlantic Ocean, south of the island dependencies of the Falkland Islands. The shores, which are covered with ice, remain largely unexplored; portions of them are named Coats Land, Caird Coast, and Leopold Coast. The sea was named for James Weddell (1787–1834), a British navigator who entered it in 1823 with the brig *Jane* and the cutter *Beaufoy* and reached the then record latitude of 74° 15′ S.

WEDDERBURN, wĕd'ĕr-bûrn, **Alexander,** 1st Baron Loughborough, British jurist and statesman: b. Edinburgh, Feb. 13, 1733; d. near Windsor, England, Jan. 2, 1805. He was a member of the bar of Scotland from 1754 till 1757, and thereafter of that of England. Elected to the House of Commons in 1761 as member for Ayr, he subsequently represented various constituencies and was by turn Tory and Whig as expediency suited him. He was appointed solicitor-general, 1771–1778, and attorney-general, 1778–1780, by Lord North, of whose North American policies he strongly approved. In 1780, he was created baron and made chief justice of the court of common pleas. He served on this bench until 1792, when he became lord chancellor. On retirement in 1801, he was made 1st earl of Rosslyn. As judge, he displayed great clarity of judgment; but as politician, despite considerable oratorical powers, he was widely distrusted.

WEDDERBURN, James, Scottish balladist: b. Dundee, 1495?; d. England, 1553. He was educated at the University of St. Andrews. Espousing the Reformation, he was forced to seek refuge in France from arrest in Scotland as a heretic. With his brothers, John (1500?–1556) and Robert (1510?–?1557), he composed several anti-Romanist ballads. With them, about 1548, he edited a song book long popular in Scotland entitled *Ane Compendius Buike of Godly*

and Spirituall Sangs, Collectit Out of Sundrie Partes of the Scripture, wyth Sundrie of Uther Ballates Changed Oot of Prophane Sangs, for Avoyding of Synne and Harlotrie; editions of the work were published by David Laing (1868) and Mitchell (1897). He was also credited with authorship of *The Complaynt of Scotland* (1548).

WEDDING ANNIVERSARIES, or celebrations, bear many familiar names from the sort of articles considered appropriate gifts on such occasions. They are as follows: Paper, one year; cotton, two years; leather, three years; books, four years; wooden-clocks, five years; iron, six years; copper, bronze or brass, seven years; electrical appliances, eight years; pottery, nine years; tin or aluminum, 10 years; steel, 11 years; silk or linen, 12 years; lace, 13 years; ivory, 14 years; crystal, 15 years; china, 20 years; silver, 25 years; pearl, 30 years; jade or coral, 35 years; ruby, 40 years; gold, 50 years; emerald, 55 years; and diamond, 60 years, or 75 years as is the custom in the United States.

WEDEKIND, Frank, German dramatist and pamphleteer: b. Hanover, July 24, 1864; d. Munich, May 1918. He first became a journalist, but drifted for a time into the employ of Maggi's soups, where he managed the advertising department (1886). He traveled as a performer in Herzog's Circus (1888) and settled in Munich in 1890, where he spent the rest of his life in literary and artistic work of various kinds. Wedekind's plays, of which many may be obtained in English translations, are a savage exposure of the sexual hypocrisy of our times, which imposes upon all classes a degree of restraint and concealment of this fundamental passion inevitably resulting in the most dangerous repressions and perversions. His first play treats this situation in a more pathetic and impressive manner than Wedekind subsequently succeeded in reaching in any of his more ambitious works. He presents in it (*Frühlings Erwachen,* 1891, *Spring's Awakening*) the early sex interest of children and the cowardice of parents in informing them on matters so vital to their future development. The terrible results of the misunderstood passion on the lives of the boys and girls in the play are perhaps more typical of Germany than of most other countries, owing to the more rigid course of German family life, but they are, in large measure, of universal application. Like several other plays of Wedekind's, *Frühlings Erwachen* has been played in New York, in English. *Erdgeist,* also dealing with sex phenomena (1895), is more colossal in its scope and almost crushing in the fury of its obsessions; its sequel, *Die Büchse der Pandora* (*Pandora's Box,* 1904), goes further in depicting the unsavory side of sex relations—Schnitzler's *Reigen* is probably the extreme in the more aphrodisiac, more tempting direction—than any other play in literature. *Erdgeist* and *Die Büchse der Pandora* are more generally known under the collective title of *Lulu,* the name of the man-consuming heroine. Other important plays are *Die junge Welt* (1897), *Der Liebestrank* (1899), *Der Kammersänger* (played in New York in English, as *The Tenor,* by the Washington Square Players, 1900), *Hidalla* (1904), *Die Zensur* (1908). The last named is a short but humorous dramatic attack on the censorship with which Wedekind had come in contact because of outspoken utterances in a previous play. In fact, he once fled from Germany from persecution for *lès majesté* (*Majestätsbeleidigung*), remained for a short time in Paris, returned voluntarily for trial, and served a short sentence in the fortress of Königstein (1900). After the outbreak of World War I in 1914, Wedekind seems, like many other German writers, to have been attracted to a more sympathetic view of German history and the German government, and wrote (1915) a rather overpatriotic historical play, *Bismarck,* glorifying the events leading up to the foundation of the German Empire. He is one of the most vigorous and original satirists of our time; his ironic, cynical estimate and rejection of the universe is apparent behind all his ingenious puns, and his grotesque humor, his eccentric caricatures, his burlesque distortions. As an artist he considers restrictions of form to be not binding, and produces not infrequently results that are refreshing or even childishly grotesque. His works (7 vols.) appeared at Munich in 1913, and include short stories as well as plays. Biographical works on Wedekind have appeared from the pens of Pissin, Raimund (1905); Kapp, Julius (1909); and Elsner, Richard (1909).

JACOB WITTMER HARTMANN.

WEDEMEYER, wĕd'ē-mī-ēr, **Albert Coady,** United States army officer: b. Omaha, Neb., July 9, 1897. Graduating from West Point in 1918, he was commissioned second lieutenant of infantry and rose through the grades to reach the temporary rank of lieutenant general in 1945. His service included duty in the Philippines, 1923–1925 and 1932–1934, and China, 1930–1932; study at the Command and General Staff School, 1934–1936, and the Kriegs Akademie (German General Staff School), 1936–1938. In 1940, he was assigned to Washington, D.C., in connection with the training of the greatly expanded United States Army, and the next year he was transferred to the war planning branch of the general staff. He continued to serve with the general staff after the United States entered World War II in December 1941, earning the Distinguished Service Medal in 1943 for his work as chief of the strategy section and later of the strategy and policy group of the operations division. Given the temporary promotions to brigadier general in 1942 and major general in 1943, in October of the latter year, he was appointed American deputy chief of staff of the Southeast Asia Command, at that period operating under Admiral Lord Louis Mountbatten against the Japanese in Burma. In October 1944 he was transferred to Chungking, China, to succeed Gen. Joseph Warren Stilwell (q.v.) in command of the United States Army forces in the China area and to serve as chief of staff to Chiang Kai-shek (q.v.). Promoted temporary lieutenant general in January 1945, he continued to serve in China until war's end. After termination of the conflict he remained in charge of American troops in that country until the summer of 1946.

WEDGE, something made of hard substance in the form of a V or double inclined plane, for splitting or pushing apart by being thrust between two surfaces. It is often regarded as one of the mechanical powers, but is really an amplification of the inclined plane. The blade of an axe, the head of a chisel and the woodman's wedge are familiar illustrations

of common wedges. A very thin wedge driven with a comparatively light hammer may be made to exert a high degree of splitting force, owing to the mechanical advantage obtained. See MECHANICAL MOVEMENTS, POWERS AND APPLIANCES.

WEDGWOOD, wĕj'wŭd, **Josiah,** English potter: b. Burslem, Staffordshire, 12 July 1730; d. Etruria, Staffordshire, 3 Jan. 1795. He was the son of a potter in the district and on the death of his father was employed in the pottery at nine. An incurable lameness later compelled him to give up the wheel and he removed for a time to Stoke, where he entered into partnership with other potters and where his talent for ornamental pottery was first displayed. In 1759 he returned to Burslem, and set up a small manufactory of his own, in which he made white stoneware, and developed the cream-colored ware for which he became so famous. He presently succeeded in producing a ware so hard and durable as to render works of art produced in it almost indestructible; and he also produced paintings on pottery without the artificial gloss so detrimental to the effect of superior work. In 1771 he erected potteries at Etruria, a village which he founded for his workmen. His improvements in pottery, which included form, substance and decoration, in all of which he attained an excellence rarely equaled, created the great trade of the Staffordshire potteries, which even during his lifetime acquired a remarkable expansion. He made 50 copies of the Portland vase, which were sold for 50 guineas each, a sum which it is said did not cover his expenditure in their production. (See POTTERY; WEDGWOOD WARE). Consult Jewett, 'The Wedgewoods' (1865); Meteyard, Eliza, 'Life' (1860); Rathbone, 'The Masterpieces of Old Wedgwood Ware' (1892-93); 'Life,' by Smiles (1894).

WEDGWOOD PYROMETER, in physics, a pyrometer in which temperature is ascertained by the contraction of baked clay, measured before and after its subjection to the action of heat.

WEDGWOOD WARE. England's most noted art potter was Josiah Wedgwood, born at Burslem, Staffordshire, in 1730. In 1754 he became Whieldon's partner, but started his Ivy House works in 1759, making "cream-color" ware. By 1773 Wedgwood's products were all being made at the newly-erected magnificent works called Etruria. "Jasper" ware (made first in 1775) was Wedgwood's most noted achievement. It was of colored body and decorated with Flaxman's reliefs in white. The texture of the paste was very beautiful and the ware was left unglazed (*biscuit*). It was used, not only in vases and table services, but also as cameos in medallions, plaques, brooches, shoe-buckles, earrings, snuff-boxes, etc. Jasper ground colors were dark and light blues, lavender, pink, two tones of green, black, so-called 'lilac" and yellow — the rarest and most coveted of all pieces. First it consisted of a solid colored body of a most beautiful grain, but was later made in a white body and dipped to give a surface of color upon which the delicate white reliefs were laid. A few pieces (made since 1790) are "tricolored." The medallions (Hackwood, as well as Flaxman, did many of the best) contained mythological subjects and beautifully executed portraits of Benjamin Franklin, Robert Boyle, Sir Isaac Newton, Priestly, Hamilton, etc. A fine white ware, named "pearl," was made from a variation of Wedgwood's "Queen's ware" paste (this was his cream-color patronized by Queen Charlotte) used on "shell" patterns and coated with pearl-shell lustre enamel washes. Gold, purple, yellow and silver (platinum) lustre pieces were made from 1792 to 1810 in tea-pots, coffee pots, cream jugs, candlesticks, trays, etc. The black stoneware that Wedgwood called "basalts of Egypt" was used on "Etruscan" (as Greek vases were then called) vase styles, medallions, panels, seals, plaques, busts, tea and coffee sets etc., with reliefs of mythological scenes, trees, horses, flowers. Noted are the busts in this ware of Zeno, Cicero, Plato, Chaucer, Milton, Spencer, Bacon, Lord Chatham of the larger sizes and the smaller Voltaire, Rousseau, etc. Most famous of Wedgwood's productions is the glass Barberini or Portland vase (see PORTLAND VASE) in black-polished earthenware background with applied white jasper bas-reliefs. Wares of mottled bodies and glazes were made in both Burslem and Etruria, Wedgwood learned this style through Whieldon's "tortoiseshell," granite, agate and other marbled wares. Another variety was the "rosso antico" or unglazed red stoneware, after the Elers brothers' style, used on cream jugs, milk jugs, etc. The so-called Greek "Etruscan" antique pieces were imitated by a method Wedgwood termed "encaustic" painting; they used an enamel paint process that produced a dull (*mat*) surface. As the pieces copied were of the Greek "Decadent" period they are not much admired; such ware is found in tea-cups, jugs, bowls, etc. Wedgwood's "bronze encaustics" still exist but the *bronze* (precipitated gold), adhering only through japanners' size is mostly worn off. Wedgwood produced scarcely any porcelain ware, but his nephew, Byerly (10 years after the great Josiah's death), made a real fine porcelain in small quantities, in unrefined decoration, mostly. Since 1872 porcelain has been produced again in Etruria. This great factory has been continued under the descendants of Josiah to this day.

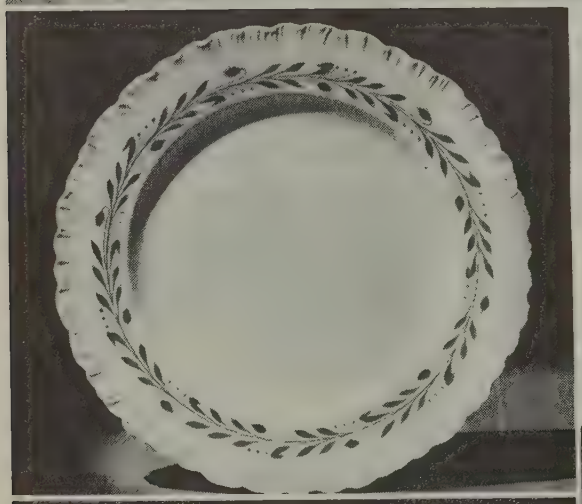
Characteristics and Marks.— True pieces having the "Wedgwood" mark and word "England" date from 1791, then the country of origin was added. "Old" Wedgwood body has been compared with a "baby's skin"; Church describes it as "ivory, neither dry and chalky-looking on the one hand, nor of waxy smoothness on the other; Yoxall says it "feels like a clay-pipe which has a film of soap-bubble over it." In Josiah's day the body had a perfect homogeneity and the workmanship showed "no ripples or stringiness" as appeared later. Marks are "Wedgwood & Bentley," "WEDGWOOD & BENTLEY," "WEDGWOOD & BENTLEY, ETRURIA," in a circle; also "W. & B." These were during the Bentley partnership, otherwise "WEDGWOOD" alone was used. The mark is always *impressed*. Much has been said of the Wedgwood forgeries, but they are so rare as to be almost considered negligible. Neither the ware nor the impressed mark are easy to closely imitate. Voyez, when dismissed by Wedgwood, made cameos in Wedgwood style and he was

WEDGWOOD WARE

Josiah Wedgwood and Sons, Inc

Top left: Marbled ware of the period of the Whieldon partnership, 1754–1759. *Top right.* Wedgwood shapes and glazes in the modern style. *Center left:* Salt glaze cornucopia produced at Burslem in 1760. *Center right:* Jasper jug of 1770 beside a modern example of the same shape in blue queen's ware. *Bottom:* three examples of modern jasper.

WEDGWOOD WARE



This cream colored pattern was given the name of queen's ware in 1765 by Queen Charlotte of England. The tableware is still in production.

Josiah Wedgwood and Sons, Inc.

Three 18th century Wedgwood designs still in production. Counterclockwise, their names are "Barley," "Husk," and "Bacchus."

a "perfect master of the antique style," but few of his cameos are known. William Adams, who worked under Josiah, made fine jasper cameos, but gave them the mark *Adams* impressed. A Herr Schmidt, at a Bayreuth factory in the 19th century, is said to have imitated Wedgwood's stoneware, using his mark.

M., and Wedgwood, H. C., *Wedgwood* (Brooklyn Museum 1948); Honey, H. B., *Wedgwood Ware* (New York 1949); Gorely, J., *Wedgwood* (New York 1950).

WEDMORE, Sir **Frederick,** English author and art critic: b. Clifton, England, July 9, 1844; d. Sevenoaks, England, Feb. 25, 1921. Educated in France, he was noted for his interpretations of French art in England. He was art critic on the London *Standard* from 1878 for nearly 30 years; lectured at Harvard and Johns Hopkins in the United States; was knighted in 1912. He edited the English edition of François-Émile Michel's *Rembrandt* (1886); wrote the *Pastorals of France* (1877); *Life of Balzac* in the Great Writers Series (1890); *Studies in English Art* (1876; 1880); *On Books and Arts* (1899); *Turner and Ruskin* (1900); *Etchings* (1911); *Memories* (1912); *Brenda Walks On* (1916).

WEDMORE, wĕd'mōr, agricultural village and parish, England, in Somerset, 7 miles northwest of Wells. It has a 15th century church. In 878 A.D. Alfred the Great, who had overthrown the Danes of East Anglia, signed here with King Guthrum the Peace of Wedmore. By this treaty the king and his chieftains agreed to withdraw into the Danelagh (q.v.), the territory in northeast England north of Watling Street, and to embrace Christianity. Guthrum changed his name to Athelstan with Alfred as his sponsor. Pop. (1931) 2,382.

WEDNESBURY, wĕnz'bĕr-ĭ, a municipal borough, England, in Staffordshire, 8 miles northwest of Birmingham, on the Tame River. It was named for the Scandinavian god Odin or Woden. A battle was fought here in 592 A.D. between the Saxons and Britons. It has a fine Perpendicular church (St. Bartholomew) and many modern buildings. As a steel center in the Black Country it manufactures railway rolling stock, steel tubing, machinery, and light metals. Pop. (1951) 34,758.

WEDNESDAY, wĕnz'dĭ, the fourth day of the week. The English name is derived from the old Scandinavian god Odin or Woden. In Anglo-Saxon, it is *Wōdnes dæg;* in Danish and Swedish, *Onsdag;* in Dutch, *Woensdag.* The Romans called it *Dies Mercurii* (Mercury's Day) and the Germans call it *Mittwoch* (midweek). See also Ash Wednesday.

WEED, Clarence Moores, American naturalist: b. Toledo, Ohio, Oct. 5, 1864; d. Lowell, Mass., July 20, 1947. After graduating from the Michigan Agricultural College in 1883, he was instructor (1904–1922), principal (1922–1932), and president (1932–1935) of the Massachusetts State Teachers College at Lowell. From 1918 to 1920 he was regional director of the United States School Garden Army. His works include *Manual of School-Supervised Gardening* (1920); *Insect Ways* (1930).

WEED, Edwin Gardner, American Protestant Episcopal bishop: b. Savannah, Ga., July 23, 1837; d. Jacksonville, Fla., Jan. 18, 1924. He was educated at the University of Georgia and at the General Theological Seminary where he graduated in 1870. He took priest's orders in the Episcopal Church in 1871 and was rector of the Church of the Good Shepherd, Summerville, Ga., from 1871 to 1886. In 1886 he was consecrated bishop of Florida.

WEED, Stephen Hinsdale, American soldier: b. New York, 1834; d. near Gettysburg, Pa., July 2, 1863. Graduated from the United States Military Academy in 1854, he served on the Texan frontier and in the Seminole wars in Florida 1855–1857; became a lieutenant in 1856; and was on duty in Kansas and in Indian wars in Utah 1858–1861. When the Civil War broke out he was promoted captain and assigned to the command of a battery in the Army of the Potomac where he became known as a "superb artillerist." He was engaged in many campaigns and at Chancellorsville received promotion to brigadier general of volunteers for his gallantry in action. Commanding a brigade of artillery at Gettysburg, he was picked off by a sharpshooter while holding Little Roundtop.

WEED, Thurlow, American journalist and political leader: b. Greene County, N. Y., Nov. 15, 1797; d. New York City, Nov. 22, 1882. At 14 he entered a printing office, but left his trade for a time to serve in the War of 1812. In 1819 he went to central New York State, where he established and edited successively *The Agriculturist* at Norwich and the Onondaga County *Republican* at Manlius. In 1822 he became editor and later proprietor of the Rochester *Telegraph,* a daily paper. During the Antimasonic excitement he stopped publication of the *Telegraph* and issued the *Anti-Masonic Enquirer.* He was twice elected to the state legislature on the Antimasonic ticket, and while in Albany became noted as a shrewd political manager. In 1830 he moved to Albany and established the Albany *Evening Journal,* which he edited until 1862. This paper was first used as a means of attacking the "Albany Regency," a body of politicians under the leadership of Martin Van Buren, and it soon became the leading journal of the Whig Party in the state. Through the influence of this paper and his political skill, Weed became the state manager of the Whig Party and later of the Republican Party. He held no public office himself, but for many years practically controlled the nominations for state officers; some of the most efficient governors of the state were elected under his management. He also took a leading part in national politics as early as 1824, and when John Quincy Adams was nominated for the presidency, he was instrumental in uniting the Clay and Adams factions. He was particularly influential in securing the nomination of William Henry Harrison in 1840, Henry Clay in 1844, and Zachary Taylor in 1848. In 1860 his first choice for the presidency was William H. Seward, but he loyally supported Lincoln after his nomination and urged his renomination in 1864. Weed had long been a personal friend of Seward and was for some time closely

associated with Seward and Greeley in what was known as «the political firm of Seward, Weed and Greeley.» In 1861 he went to Europe on a diplomatic mission to place the North in a favorable light before foreign governments and to prevent their intervention in behalf of the South. After 1865 he was for a time a member of the editorial staff of *The New York Times;* in 1867–68 was editor of the *Commercial Advertiser* in New York. His health then forced him to resign continuous journalistic work, but he continued to write occasionally for newspapers and periodicals, and though he took no active part in politics, his advice was sought by Republican leaders and had no small influence in shaping the policy of the party. He published *Letters from Europe and the West Indies* (1866), and prepared his *Autobiography,* which was published after his death (1884). Consult Barnes, *Memoir of Thurlow Weed* (1884); Alexander, *Political History of New York* (New York 1906).

WEED, Walter Harvey, American geologist: b. Saint Louis, Mo., 1 May 1862. He was graduated as mining engineer from Columbia University, School of Mines (1883) and appointed assistant geologist, United States Geological Survey in that year. In 1883–89 he was engaged in Yellowstone Park investigating hot springs and geysers, and glacial and sedimentary formation. To him is due the discovery that the brilliant coloring about hot springs and geysers are not mineral but due to living algae; and he also found and described Death Gulch. He also made the discovery that Death Gulch gave out carbon dioxide gas from an extinct hot spring, and it was this that killed wild animals that strayed there. He was occupied in general geologic exploration work in Montana, 1889–98. His most notable contribution to science was the theory of secondary enrichment of mineral deposits published in 1899, now generally accepted. This was followed by the theory of enrichment by ascending alkaline waters. He was one of the first to describe contact metamorphic ore deposits, and to interpret replacement deposits correctly. He was a member of practically all important scientific societies and was appointed special expert and commissioner on copper for Louisiana purchase exposition, 1904. In 1906 he resigned from United States Geological Survey to become chief geologist and examining engineer for General Development Company, and in 1910 went into private practice as consulting engineer and mine valuer. In later years he was an expert witness in many important mining lawsuits. His publications include *The Mines Handbook,* formerly *The Copper Handbook* (1911–25); *Nature of Mineral Deposits* (adapted from Beck's German treatise); *Geology of Butte, Montana; Geysers; Secondary Enrichment;* and many papers of the United States Geological Survey and in *Transactions* of the American Institute Mining Engineers. He died in California, 5 Sept. 1944.

WEEDEN, William Babcock, American manufacturer and economic and historical writer: b. Bristol, R.I., 1 Sept. 1834; d. 1912. He studied at Brown University, and then engaged in the manufacture of woolen goods in Providence. In 1861 he joined the Union Army as first lieutenant of artillery; was promoted captain after the first battle of Bull Run; was present during the siege of Yorktown, and took part in the engagements at Hanover Court House, Mechanicsville, Gaines' Mill and Malvern Hill. In August 1862 he resigned and resumed business in Providence. His publications include *Mortality of Prohibitory Liquor Laws* (1875); *Social Law of Labor* (1882); *Economic and Social History of New England 1620–1789* (1890); *War Government* (1906); *Early Rhode Island* (1911).

WEEDS are plants growing where they are not desired. There are no plants which are weeds, *per se,* since in nature each plant has its place, and since in cultivated areas any plant, useless or useful, may become a weed. Thus grass would be considered a weed in a bed of garlic, and vice versa. Many plants, however, are popularly dubbed weeds because they are troublesome in fields and gardens, but even among these are not a few which are cultivated; for instance, purslane, lamb's quarters and sorrel. Far from being the useless and obnoxious things that they have long been reputed to be, weeds have performed a distinct service, which they still continue, in agriculture; they have compelled the husbandman to practice clean cultivation, upon which the success of his crops very largely depends.

Weeds often must be eradicated upon land that has become foul under neglect. Upon pastures and lawns that commence to fail the two principal ways of management are to make more grass grow or to plow the land and grow some other crop upon it for a year or more. The former is usually more feasible with lawns; the latter with meadows and pastures. Often a reseeding to grass will be sufficient. The plantain, dandelion and similar weeds troublesome in lawns may be cut out individually, but to keep them out the growth of grass must be encouraged by sowing extra seed and by fertilizing. In land that has lain fallow the annual weeds may be destroyed by frequent cultivation; biennial and perennial weeds, by short rotations of crops, especially such as include intertillage crops, like potatoes, beans and turnips. The one necessity to observe in combating perennial weeds is to prevent their forming leaves and thus elaborating food. In low grounds where sedges, rushes and bracken often abound, the land may be rid of these weeds by draining. In gardens many weeds may be «smothered» by growing leafy crops which will shade the ground. Ground which is kept free from weeds in the early months may become choked with weeds toward autumn and these may reseed the ground for the following year. Mowing before the plants blossom, or plowing the ground are often practiced. In some cases, however, the plants may be allowed to remain as a cover crop to prevent the washing of the soil during winter. This practice is most common in orchards. A cover crop sown by the orchardist is preferable.

Besides the usual means of seed dispersal, such as wind and water, weeds are frequently distributed by means of baled hay, manure, and imperfectly cleaned seeds of the crops sown. This last is particularly prevalent with seeds hard to clean, such as grass and clover. Hence the advisability of purchasing only the

best seeds. It is not remarkable that many of the most troublesome weeds are imported from foreign countries, because being removed from their natural controls they find less resistance and spread accordingly.

Weeds are often of service in aiding the farmer to judge the needs of his land, since many kinds grow only where the conditions are peculiarly adapted to them. The character of their growth also indicates the quality of the soil. Wild carrot and the oxeye daisy grow only on poor soils, or soils that have been robbed of their fertility. Sheep sorrel indicates acid land and the necessity of applying lime to "sweeten" the soil. Bracken, sedge, and moss show that the land needs drainage. Dark green foliage and large size of plant and leaf are good indications of abundant nitrogenous plant food in the soil; while yellowish foliage and sparse, stringy growth shows lack of this material.

WEEHAWKEN, wē-hô'kĕn, township, New Jersey; in Hudson County; altitude 10 feet. It is situated on the Hudson River opposite New York City, with which it is connected by the Lincoln Tunnel (vehicular). It has textile-processing and other industries, and is served by the Erie, the Hoboken Manufacturers, the New York Central, and the New York, Ontario and Western railroads. Weehawken was incorporated in 1859. Here, on a little level plot of ground about 20 feet above the river, took place on July 11, 1804 the famous duel between Alexander Hamilton and Aaron Burr. The site of the duel was torn away in 1883 to make room for railroad tracks, and the monument which marked the spot where Hamilton fell was moved to the heights above. Pop. (1950) 14,830.

WEEK, a period of seven days, one of the common divisions of time. The week is an arbitrary division of time, and the question when, why and by whom it was first adopted necessarily arises in connection with its actual prevalence. One explanation is that the number seven occurs so conspicuously in mythical and occult lore. It was also early used as an indefinite unit, and things were counted by sevens, where later they were enumerated by dozens or hundreds. Another natural explanation offered is that it has been adopted as a quarter lunation; but as there is no absolute necessity for dividing the month into four, and a large fraction is needed to make the weekly square with the lunar periods, this explanation is not satisfactory. The week is, in fact, a much closer division of a year than of a month; but the division of the year into 52 portions is so purely arbitrary that this can hardly suggest the origin of the week. The convenience of some short recurring period or cycle of days is obvious, and it is the prevalence alone, and not the occurrence of a particular cycle, that has to be accounted for.

The practice of antiquity on the subject does not seem to have been so uniform as is sometimes supposed. Among the nations who adopted the week as a division of time, the Chinese, Hindus, Egyptians, Chaldeans, Jews, Persians, and Peruvians (Incas) have been mentioned, but in some cases the antiquity of the practice is doubtful, and in others the name has been appplied to other cycles than that of seven days. The nations with whom the weekly cycle has been traced with certainty to the greatest antiquity are the Egyptians and the Hebrews. With the former we only know of its existence, but with the latter it had a much more important character. Their earliest records speak of its existence, and refer it to a period previous to that of the nation itself. Laban, the uncle of Jacob, alludes to the week as an established measure of time in Genesis 29:27. The origin of the week is further ascribed in the Jewish Scriptures to the creation of the world, and is wrought into the institutions of the nation in a variety of ways, but particularly by the consecration of the seventh day to the worship of the Creator. The Hebrew word for week is of a general signification, and applies equally to a period of seven days, seven months, and seven years, each of which had a particular celebration attached to it in the Hebrew ritual; hence the use of days to represent years in the prophetic writings is according to the natural genius of the language. The number seven had a mystic significance attached to it in the symbolism of the Jewish religion in a variety of other ways.

The Romans and Greeks each divided the month into three periods (see CALENDAR), and were not acquainted with the week until a late period. The Romans, however, had for civil uses, as the arrangement of market-days, a cycle of eight days, the ninth day being the recurring one, instead of the eighth, as with us. The use of the week was introduced into the Roman Empire from Egypt about the first or second century of the Christian era, and had been recognized independently of Christianity before the Emperor Constantine confirmed it by enjoining the observance of the Christian Sabbath. The names given by the Romans to the days of the week, and which have pervaded the Romance languages, were derived from the planetary system, which was supposed to consist of the sun, moon and five planets, Mars, Mercury, Jupiter, Venus and Saturn.

WEEKES, wēks, **Henry**, English sculptor: b. Canterbury, 1807; d. Pimlico, London, May 28, 1877. He was for many years the principal assistant of the sculptor Sir Francis Legatt Chantrey. He was elected to the Royal Academy in 1850 and became professor of sculpture there in 1873.

Besides the earliest bust of Victoria as queen (1838), he executed statues of Charles II for the House of Lords; Sir Francis Bacon for Trinity College, Cambridge; and Hugh Latimer, Thomas Cranmer, and Nicholas Ridley for Martyrs' Memorial, Oxford.

WEEKS, wēks, **Edwin Lord**, American artist: b. Boston, 1849; d. Paris, Nov. 17, 1903. He was a pupil of the Beaux-Arts (Paris), of Jean Léon Gérôme and Léon Bonnat, and sketched and painted in Cairo, Jerusalem, Damascus, Tangier, and India, obtaining there material for the genre scenes from Eastern life with which he won his reputation. A frequent exhibitor at the Salon, he obtained honorable mention there in 1885. Among the other distinctions which he received were the diploma of honor at the Berlin international exhibition in 1891, and a special medal and prize in 1896 at the empire of India exhibition (London). Specimens of his work are in the Pennsylvania Academy of Fine Arts, Philadelphia; the galleries of New York City; and the Corcoran Gallery of Washington. Among his paintings are *Cup of Coffee in the Desert; Jerusalem*

from the Bethany Road'; 'Pilgrimage to the Jordan'; 'Scene in Tangier'; 'Arab Story-Teller' (exhibited at the Centennial Exhibition, Philadelphia, 1876); 'Departure for the Hunt — India'; 'Moorish Camel-Driver.' He also wrote 'From the Black Sea Through Persia and India' (1895), and 'Episodes of Mountaineering' (1897).

WEEKS, John Wingate, former United States Secretary of War: b. Lancaster, N. H., 11 April 1860; d. there, 12 July 1926. Reared on a farm, he was graduated from the United States Naval Academy in 1881; served as midshipman 1881–83; was assistant land commissioner of the Florida Railroad, 1886–88; member of Hornblower and Weeks, bankers and brokers of Boston, 1888–1912; alderman 1900–02 and mayor 1903–04 of Newton, Mass.; chairman of the Republican State Convention in 1905; member of Congress 1905–13 from the 12th Massachusetts District; member of the United States Senate 1913–19; received 105 votes for the Presidential nomination in 1916; in 1898 commanded a division of the Massachusetts Naval Brigade with rank of captain. He was Secretary of War from 1921 until October 1925. He successfully reduced the enlisted strength of the army from 250,000 to 150,000 men and put into full effect the National Defense Act.

WEEKS, Raymond, American philologist and phonetician: b. Tabor, Iowa, 2 Jan. 1863. He was graduated at Harvard University in 1890 and later studied at the universities of Paris and Berlin, taking his Ph.D. at Harvard in 1897. He was professor of the Romance languages at the University of Missouri in 1895–1908; held that chair at the University of Illinois in 1908–09, and at Columbia University, 1909–29. He was in the ambulance service in France in 1917–18. In 1910 he was one of the founders of the *Romanic Review;* in 1913 assistant editor of the 'New Standard Dictionary,' and was general editor of the Oxford French **Series;** was joint author of 'The N. E. A. Phonetic Alphabet' (1916); has contributed verse and short fiction to magazines and is author of 'Origin of the Covenant Vivien' (1902); 'La Chevalerie Vivien' (1909); 'Ode to France' (1917); 'Boys' Own Arithmetic' (1924); 'The Hound-tunes of Callaway' (1927).

WEEKS, Feast of (Heb. *Shabuoth*), the second of the great Hebraic religious festival. it is thus called from the fact that it forms the culmination of the seven weeks succeeding the Passover feast. Primarily it appears to have been connected with the celebration of the end of the harvest, but later also with the giving of the Law on the 50th day after the departure from Egypt. In the New Testament it is called Pentecost (q.v.), the Greek word (*πεντηκοστή*) signifying 50th (from *ἡμέρα*, day).

WEEMS, wēmz, Mason Locke, American Protestant Episcopal clergyman: b. Maryland, about 1760; d. Beaufort, S. C., 23 May 1825. He began the study of medicine, but gave it up and went to London, where he was educated for the clerical profession, but found no bishop in England to admit him to holy orders. There was then no Anglican bishop in America, and the professional plans of Weems were obstructed by peculiar difficulties. (For an account of them consult McMaster's 'History of the People of the United States,' Vol. I). Returning to this country, he preached at different places, apparently never having a regular charge, although it has been said that the rectorship of Mount Vernon parish (there was no such parish) was held by him before the Revolution, as claimed by himself; also that he officiated in the old Pohick Church, of which Washington was an attendant, which indeed he may have done, but not until long after Washington's attendance there had ceased. About 1790 he became a book agent for Mathew Carey (q.v.), and traveled through the South selling works, some of which were his own. He made himself popular by exercising his talents for comedy and his skill with the violin, probably diverting and (through his sermons) exhorting the people by turns. A book of his own writing which he offered for sale was 'The Drunkard's Looking Glass' (6th ed., 1818). His 'Life of Washington,' by which he is best known, first appeared in 1800, and during the 19th century the number of its editions exceeded 70. The traditional conception of Washington rests mainly upon this work, as do the story of the cherry-tree and other anecdotes which historians reject, most of which first appeared in the 5th edition (1806). His other publications, all more or less tawdry and inaccurate, include 'Life of General Francis Marion' (1805); 'The Philanthropist' (10th ed., 1809); 'God's Revenge Against Gambling' (3d ed., 1816); 'Life of Benjamin Franklin, with Essays' (1817); 'Life of William Penn' (1819); 'Hymen's Recruiting Sergeant' (7th ed., 1821 and 'The Bad Wife's Looking Glass' (2d ed., 1823).

WEENDIGO, wĭnd-ēgō (meaning «cannibal») mythical tribe of Indians believed in by the Algonquin and other eastern races. The Chippewa and the Ottawa thought they inhabited an island in Hudson Bay; while certain other tribes placed them indefinitely in the far north country. Indian stories tell of a terrible Weendigo with two faces and monstrous ears, who could see and hear everything. The «great weendigo» was a monster so huge that his step shook the earth. So terrible was his gaze that no one looked upon him and continued to live. For this reason no one could accurately describe him. He lived far within the forest; but, for the same reason, no one knew exactly where. Like the forest Indians, he was much of a wanderer, and consequently was found, now in one place, now in another. For this reason he was the more to be feared, as one was liable to come upon him suddenly when least expected. But though no one had lived to describe him, there were many who had heard his tramp as it shook the forest and his terrible voice as he roared in rage. Sometimes the Great Weendigo makes himself small and induces the unwary warrior or hunter to follow him; but he who does so never returns. He is much taller than the tallest wigwam ever built, and his ears stick out like those of a mountain cat. These he uses for hunting bags; and in them he stores, for the time being, all he does not care to eat. The Great Weendigo is supposed to be especially fond of children and to keep a supply of them constantly in his great ears. Sometimes children thus imprisoned have escaped from the Weendigo, when the proper magic has been brought to bear upon the giant. A customary way of frightening Algonquin children into being good was to tell them the Weendigo would

catch them and put them in his ears, or roast them and eat them. Numerous mythical folk-tales have grown up about the Weendigo, many of which are imaginative and dramatic. The Great Weendigo had the power of self-transformation; and he frequently changed his form to gain his ends. The Weendigo was firmly believed in from the Hudson Bay to the head of Lake Superior and throughout all the Algonquin country from this line eastward.

WEENIX, Jan, yän vā'nĭks, THE YOUNGER, Dutch painter, son of Jan Baptist: b. Amsterdam, 1644; d. there, 20 Sept. 1719. He painted landscapes, animals, flowers and fruit, but excelled in the representation of dead game and hunting scenes. His pictures of this class are unrivaled by any productions of the Dutch schools, and command large prices. He finished with extreme neatness, and exhibited a clear and brilliant coloring and a wonderful knowledge of chiaroscuro.

WEENIX, Jan Baptist, Dutch painter: b. Amsterdam, 1621; d. Ter May, near Utrecht, 1660. He was instructed by Abraham Bloemart and Nicolas Mojert, and at 22 visited Rome, where he acquired a reputation by his Italian seaports and landscapes with architectural accessories. The last 12 years of his life were passed in Holland. He was a rapid painter, having been known to finish three half-length portraits with accessories in a single day, and excelled in history, portrait, animal, landscape and marine painting, being on the whole most distinguished in the last-named department.

WEEPING CROSS, a cross of stone or wood, erected at the side of a road, at which penitents prayed and wept for their sins. Hence the old English saying, "To return by weeping cross," that is, to return in sorrow from some message or undertaking. These crosses were removed in England when that country became Protestant, and the saying is now obsolete.

WEEVER (variant of weaver, or of the obs. *wiver*, from Lat. *vipera*, viper), a fish of the genus *Trachinus*, two species of which are recognized: *T. vipera*, five to six inches in length, and *T. draco*, 10 to 12 inches. They possess sharp opercular and dorsal spines, with which they can inflict a painful wound. The sting is believed not to be poisonous, but it is very similar to that of the sting-ray (q.v.). The name weever is hence applied to any of the *Trachinidæ*.

WEEVIL, a general name applied not only to various genera of adult beetles but also to their larvæ. They form a group *Rhynchophora*, or snout-beetles, so called from the characteristic production of the head in the form of a prominent snout, bearing the elbowed antennæ at the sides and the small mouth at its tip. There are several families, but most of these beetles belong to the Curculionidæ, which is said to include upward of 600 genera and 20,000 species. All of them are vegetarians and the larvæ are little white or yellow, fat footless grubs which mostly live within the tissues of plants, and are especially destructive to nuts, seeds and fruits. One of the most conspicuous and harmful is cotton-boll weevil (*Anthonomus grandis*). It is about one-fifth of an inch long and may be differentiated from related species by the fact that the tibiæ of the first pair of legs are provided with two small spines. Immediately after transforming from the pupal state the color is reddish but some time after emergence the color becomes considerably darker. The grub-like larvæ are considerably longer than the adults, strongly curved, white with pale yellowish heads. The eggs are deposited in punctures made by means of the beak of the female weevil in the buds (called squares) and bolls. The larvæ devour the interior. Infested squares practically invariably fall to the ground but bolls always remain attached to the plant. In the case of the squares, of course, the fruit is ruined. In case of bolls only the infested like or apartment is destroyed. The life-cycle is completed in about 20 days and there is an inextricable confusion of generations. The winter is passed in the adult stage, the individuals flying to the woods or seeking shelter in débris around or inside of the cotton fields.

This insect probably originated in Central America. It was introduced into the United States near Brownsville, Tex., about 1892. By 1895 it became established as a serious pest and today it has become thoroughly established over nearly the whole cotton belt except California and is a permanent menace to the crop. By 1924 it had reached Virginia, having traveled from 40 to 70 miles annually, causing an annual loss of many millions of dollars. The following method of control is recommended; uproot and burn all plants in the fall; plant early maturing varieties of cotton and hasten the crop; practice rotation of crops; burn trash where they hibernate; dust with arsenate of calcium containing not less than 40 per cent nor more than 75 per cent water soluble arsenic pentoxide and a density of not less than 80 nor more than 100 cu. in. per pound. Distribute by hand dusters, power dusters or airplanes at night, three applications at four-day intervals. Dust only when the yield is at least one-half bale per acre. Recently sodium fluosilicate has been used effectively.

The grain-weevil (*Sitophilus granarius*) is a little dark red beetle about an eighth of an inch long. The eggs are deposited on wheat after it is stored, and the larvæ burrow therein, each larva inhabiting a single grain. The rice-weevil (*S. oryzæ*) destroys rice and Indian-corn in a like fashion; this species has four red spots on the elytra or wing-covers. Another species (*Calandra palmarum*) infests palm-trees, is common in Guiana and attains a length of two inches, the larvæ burrowing in the pith of the trees. *C. sacchari* inhabits sugar-canes. The genus *Rhynchites*, of which the grape-weevil (*R. bacchus*) is an example, has the head broad behind; it devastates the growing vines, and strips them of their leaves. The plum curculio (*Conatrachelus nenuphor*) causes great damage to plums, cherries and other stone fruits. The eggs are laid one at a place in the young, forming fruit, upon the flesh of which the larva feeds, causing it to drop prematurely or to become "wormy." The beetle is less than one-fifth of an inch long and dark brown spotted with black and yellow. The familiar chestnut-worm is the larva of *Balaninus rectus*, remarkable for the great length of the snout, which exceeds the short robust body and which is adapted for piercing the thick burrs of the

young chestnuts, permitting the deposition of an egg in the kernel. Related species of the genus infest other nuts. Equally troublesome to fruit-growers are the species of *Anthonomus,* of which one pretty little weevil (*A. signatus*) causes great damage to the Sharpless and other staminate varieties of strawberry. This species attacks the flowers, and the larvæ feed upon the pollen. Quite different in its habits is the potato weevil or potato-stalk borer (*Trichobaris trinotata*), the larva of which bores passages in the stems of potatoes and wild plants of the same family. The clover-weevil (*Phytonomus punctatus*) has green larvæ, which differ from all of the foregoing in living exposed to the air and light, though they feed chiefly at night. They eat the leaves, and as they hibernate in the ground and begin to feed almost as soon as the clover sprouts in the spring they become most serious pests. The adults are nearly a third of an inch long, thick-bodied and short-snouted, with strongly knobbed antennæ.

To the family *Bruchidæ* belong the extremely destructive pea and bean weevils, which have the proboscis short and curved down on the breast and the antennæ not elbowed. They are small beetles with stout bodies and the swollen abdomen often projecting beyond the tips of the wing-covers. Unlike the *Curculionidæ,* which become quiescent and assume an appearance of death, these beetles are extremely active and fly when disturbed. The larva of the pea-weevil (*Bruchus pisi*) damages peas, the eggs being laid when the peas are ripening. They destroy much of the substance of the grain, lessen its germinating power and pupate in its interior. The mature insect is black marked with white spots, and about an eighth of an inch long. The *B. pisi* was at one time so destructive in North America that its ravages threatened to wholly exterminate the pea crops. Several species are named corn-weevils, from their destructive effects in granaries. *B. granarius* also attacks peas, and one species infests the cocoanut. The bean-weevil (*B. fabæ*) is plain brown in color but otherwise similar.

Weevils are very difficult to control on account of their small size, inconspicuousness and the fact that the destructive larvæ are generally beyond the effective reach of insecticides. The best measures consist in the total destruction by burning of all infested fruits, nuts or stems, the digging or plowing in the late fall of the ground in which the pupæ hibernate, and in the case of the pea and bean weevils the fumigation with carbon bisulphide of all infested seed. Consult Harris and Flint, 'Insects Injurious to Vegetation' (New York 1884); Saunders, 'Insects Injurious to Fruits' (Philadelphia 1883); Smith, 'Economic Entomology' (Philadelphia 1896); also Bulletin 731 (Washington 1918) and Farmers' Bulletin 1262 (1922) of the U. S. Department of Agriculture and other special government publications.

WEEYOT. See WISHOSKAN.

WEIDNER, wīd'nėr, **Revere Franklin,** American Lutheran theologian: b. Centre Valley, Pa., 22 Nov. 1851; d. Tangerine, Fla., 5 Jan. 1915. He was graduated from Muhlenberg College, Allentown, Pa., in 1869, from the Lutheran Theological Seminary, Philadelphia, in 1873, and after being ordained to the ministry was pastor at Phillipsburg, N. J., 1873–78, and at Philadelphia 1878–82. He was professor of English, history and logic at Muhlenberg in 1875–77, and in 1882–91 was professor of dogmatics and exegesis at Augustana Theological Seminary, Rock Island, Ill. In the last-named year he accepted the presidency and the chair of dogmatic theology at the Chicago Lutheran Theological Seminary. He published 'Commentary on the Gospel of Mark' (1881); 'Biblical Theology of the Old Testament' (1886); 'Annotations on the General Epistles' (1897); 'Theologia; or the Doctrine of God' (1903); 'Studies in Exodus' (1903), etc.

WEIGALL, Arthur Edward Pearse Brome, English Egyptologist: b. 20 Nov. 1880; d. 2 Jan. 1934. Studied at Wellington College and at New College, Oxford; commenced archaeological investigations when 18; assisted Petrie at Abydos 1901–02; excavated at Sakkarah in 1902–04; and the mortuary temple of Thothmes III at Thebes in 1905; was inspector of antiquities under the Egyptian government 1905–14, when he retired. Among his investigations are noted the antiquities of Nubia, the eastern desert and Imperial Prophyry quarries, Wady Hammonat and Kassair and the tombs of the nobles of Thebes. Upon his return to London in 1914 he designed stage scenery and costumes with considerable success. He wrote 'A Report on the Antiquities of Lower Nubia' (1907); 'A Catalogue of the Weights and Balances of the Cairo Museum' (1908); 'A Guide to the Antiquities of Upper Egypt' (1910); 'The Treasury of Ancient Egypt' (1910); 'History of Events in Egypt from 1798 to 1914' (1915); 'Life of Akhnaton, Pharaoh of Egypt' (1910, rev. 1922); 'Life of Cleopatra' (1914, rev. 1924); 'Madeline of the Desert' (1920); 'Garden of Paradise' (1923); 'Tutankhamen and Other Essays' (1923); 'Ancient Egyptian Works of Art' (1924); 'History of the Pharaohs' (1922–26); 'The Not Impossible She' (1926); 'Flights Into Antiquity' (1928); 'Nero' (1930).

WEIGAND, vī'gänt, **August,** Belgian musician: b. Belgium; d. Oswego, N. Y., 26 May 1904. He began his musical career as organist of Saint Giles' Church, Liège, and subsequently long presided at the organ of the Sydney, New South Wales, town-hall, then the largest instrument in the world. His achievements as organist and composer won for him a professorship in the Royal Conservatoire at Liège. He came to the United States in 1903, gave numerous concerts, opened the large organ at Brown University and was appointed to open the grand organ at the Louisiana Purchase Exposition, Saint Louis, in June 1904. In a dozen years he gave throughout Europe more than 1,800 concerts. He was the recipient of various distinctions, and was generally known as Chevalier Weigand.

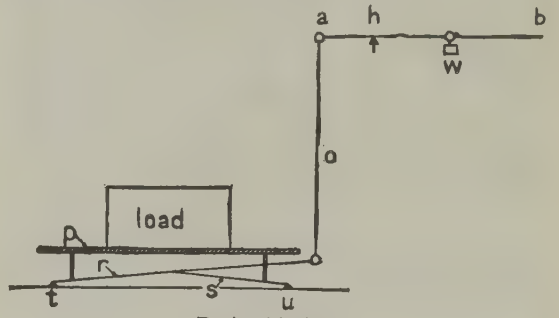
WEIGHING MACHINES, mechanical devices for ascertaining the weight of objects. It is to be understood, however, that the element thus determined is a relative value, and is entirely independent of the magnitude of the force of gravity or the tendency of a body to fall. It is measured at sea-level and at the

mean diameter of the earth. For example, the force of gravity decreases with elevation, but a commercial unit of weight such as a "pound" is the same at the top as it is at the foot of a mountain. In the usual method of determining weights of this character, a "unit of weight" is first adopted, and then a "set of weights" procured, each of which represents a certain predetermined number of the units. With these, by the aid of a machine so constructed as to be capable of establishing an equilibrium between any number of the weights and the article being weighed, the ratio of the weight of the article to that of the adopted unit is determined. Such machines may be conveniently arranged in three general classes — "equal armed" balances, "unequal armed" balances, and "spring" balances.

Equal armed balances are represented by the various forms of "scale-beams," in which the scale-pans hang below the beam, and the "counter-scales" in which the scale-pans are above the beam, both forms operating by adjustment of equilibrium between a known and an unknown weight. Unequal armed balances are represented by those consisting of a single steelyard, and those formed by combinations of unequal armed levers and steelyards, such as platform scales and weighbridges, in which a small known weight at one end of a beam counterbalances a heavy unknown weight at the other end. Spring balances operate on the principle that, when a helix is subjected to a tension, the amount of elongation increases proportionally with the increase in the force of tension. In the simplest form, it consists of a helical spring of hard steel of a high elastic limit. As commonly used it is suspended from a fixed point by a hook at its upper end, while its lower end is bent into a hook, which is crossed by another hook to which the article to be weighed is attached. An index attached to the spring and moving along the face of a graduated plate indicates the amount of tension in terms of the adopted unit of weight. The contrivance is so arranged that the axis of the spiral is always a plumb line, under tension or at rest, and is capable of weighing only an amount within the elastic limit of the spring. The capacity of such balances is generally small, and they are extensively used in shops, and for other purposes where a high degree of accuracy such as may be obtained by lever balances is not required. On the other hand, the various forms of dynamometers employed for registering the pull of locomotives are made with enormous capacities. In this connection the "torsion balance" may be conveniently mentioned, although in reality it is a machine generally used for the purpose of measuring horizontal forces, rather than weights as here understood. In its simplest form it consists of a beam, supported by a wire stretched horizontally which passes through its centre of gravity. When twisted by the application of a weight to the beam, the elasticity of the wire acts the part played by the weight of the beam in an ordinary balance. For measuring horizontal deflections caused by electric, magnetic, and other forces, the wire is stretched vertically.

For all forms of weighing machines of the equal armed type with small capacities. such as counter-scales, chemical and assay balances, etc., see BALANCE.

The majority of the machines of large capacity known as "platform-scales," used for weighing heavy loads such as carts loaded with grain, hay, coal, building materials, etc., operate on the principle of the lever, and belong to the class designated as unequal-armed balances. They are sometimes arranged as "decimal balances," the ratio between the small known weight on the weighing beam and the unknown weight on the platform or bridge being indicated in multiples of 10. Such a balance consists of a lever (ab), suspended at (h), and connected by the rod (o), with two levers (r) and (s), hinged at (t) and (u), respectively. A platform (p), resting by means of standards upon the levers (r) and (s), accommodates the load which is counterbalanced on the long arm of the weighing beam or lever (ab), by a sliding weight— (w). When a load is placed upon the platform (p), the levers (r) and



Decimal Balance.

(s), are depressed, and exert a downward pull on the short arm of the weighing beam through the rod (o), with a consequent lifting of the long arm. This pull is counterbalanced by sliding the weight (w) along the long arm until it is brought into a horizontal position. The weighing beam being graduated with an adopted unit of weight and fractions thereof (usually pounds), the weight of the load on the platform is ascertained by a simple direct reading of the graduated scale. In the smaller scales, the weight (w) equals one pound, and counterbalances a load of 100 pounds upon the platform, but it is evident, that by varying the number of levers and the relative lengths of their arms, any desired ratio between the load and the counter weight may be readily obtained. In scales used for weighing loaded wagons and cars, the ratio varies from one to 500, or one to 1,000. Cattle scales are capable of weighing from 10 to 200 head of cattle at a single operation, and the capacity of grain scales ranges upward of 500 bushels, while the large iron and steel manufacturing plants and gun shops employ machines with capacities exceeding 100,000 pounds. The machine at Watervliet Arsenal, Watervliet, N. Y., used for weighing guns, has a capacity of 300,000 pounds.

With the advent of the automobile and its far greater capacity of burden the platform-scales formerly used to weigh loads drawn by horses have become obsolete, and with the rebuilding of such weighing machines automatic recording devices have been added, so that a modern scales of this class will weigh a load of coal approximating five tons within the

limit of error of three ounces, and print the correct weight upon a tape without the services of any attendant.

Self-discharging scales are also much in use for measuring units of weight; as for instance the filling of packages of commodities, as coffee, sugar, flour, and cereals. The same idea is embodied in receiving scales in large establishments, where coal, feed-water, sand, cement, ore, and crushed stone, are weighed as delivered, the receiving hopper discharging when the weight equals one ton, 100 pounds, or any other desired amount.

Railroad or track-scales are of prodigious size and capacity. The largest of this type in the world is a "suspended-platform" scale in the West Albany yard of the New York Central Railroad. The weighing rail is 90 feet long, and the capacity is 825 tons.

A new idea in heavy-work scale construction is known as the flexure-plate scale. In this type thin plate fulcrums of chrome-vanadium-steel take the place of the usual knife-edge pivots. They operate by bending, instead of frictional movement on bearings. They have been found of most dependable accuracy and unequaled endurance, being unaffected by dampness or changes of temperature, and thus entirely free from the variations common to the ordinary track-scales.

The conveyor scale weighs material as it passes on a conveyor belt, making use of electricity instead of weights for the recording. The belt is so arranged in reference to the weighing apparatus that the full belt is weighed against the empty return belt. A vertical plunger in a tube partly filled with mercury rises and falls in the tube according to the weight of material passing. The moving mercury brings more contact points into action the greater the thrust of the plunger, and the varying current makes its record automatically on a traveling tape. A standard comparison of amperes per hour, and tons per hour, gives the figure by which the weight is readily computed.

The computing scale is a machine which carries an attachment for indicating a certain limited range of prices. Usually it carries a cylinder covered with a paper roll ruled in many different proportions, each ruling indicative of a certain price unit. The cylinder turns with the weight, thus showing the cost at several different prices per pound.

The difficulty of exactitude in weighing is recognized and a legal "tolerance," as it is called, is permitted, within which no one can be accused of dishonesty or fraud. These tolerances are as follows: on counterpoise scales, one grain on one fourth ounce; two grains on one ounce; 10 grains on 10 ounces; 10 grains on one pound; 40 grains on 10 pounds; 100 grains on 50 pounds. On platform scales one ounce is allowed on 50 pounds; one pound on 800 pounds; two pounds on one ton. On railroad or track-scales the permissible error is four pounds per ton.

WEIGHT THERMOMETER. See THERMOMETER.

WEIGHTS AND MEASURES are fundamental necessities of commerce, industry and science. Measurement is required in the exploration of lands and waterways, in their location and transfer, in the work of construction of buildings, bridges, railroads and other engineering works, in the manufacture of foods, in the preparation of compounds and in the purchase, shaping and sale of materials. Weights and measures are essential to all barter of goods. Here, the accuracy may range from the "heap" or "pile" of ancient times, to the one one-hundredth of a cent used in cotton and spelter quotations "on change," estimates of value which we call prices being based on a specified weight of gold. Weights and measures are essential in all construction whether the precision be the "rule of thumb," or the millionth of an inch in optical work, or the one-ten-thousandth of an inch in the manufacture of fine machinery. The pharmacist with his weights compounds the prescriptions which mean health and life to the sick. In the extractive and compounding industries, weights and measures are used to determine the essential proportions in analyses and compounds, and precision is the main condition of reproducibility of results. Likewise, the manufacturer must accurately weigh, measure and test his materials to secure perfect construction. Surveying and navigation would be very primitive were it not for the rigorous measurements of base lines, accurate triangulation, precise leveling, including even such delicate measurements as the variation of latitude. Weights and measures are in fact necessary in the discovery, development, and statement of industrial and scientific facts.

The birth of the exact sciences was coincident with the development and application of quantitative measurements to the phenomena of nature, and the rapid growth of modern science has since been parallel with that of precision. James Watt was one of the earliest to suggest international standards which would enable scientific results when published in terms of such standards as to be intelligible and reproducible the world over. Precise and uniform standards made possible the interchangeability of parts in machinery, first practically applied by Eli Whitney and today one of the most important principles in manufacturing.

Classification.—Weights and measures ordinarily include those defining length, area, volume, capacity, and weight. These are relatively the most important measures used by man. However, within the last half century when such products as power, electric current, heat, light, refrigeration, and services have entered the world's markets as commodities for manufacture, purchase and sale—the scope of weights and measures has widened to include units used in the measurement of velocity, pressure, energy, electricity, temperature, and illumination. Technical requirements also resulted in a series of compound units such as the knot, a unit of speed for vessels of one minute of the earth's circumference per hour; the ton-mile used in transportation rates and statistics; the foot-pound, a unit of energy; the dyne, the international unit of force and other units of the centimeter-gram-second system of scientific units in use throughout the world. Such compound units are multiplying apace with technical needs, and have proven of inestimable value and economy by the facility and precision which they afford in conveying exact quantitative results of experiment and observation. With advancing needs the units of weight and measure have extended to microscopic and to telescopic dimensions. The millimicron of the physicist and the still smaller Angstrom unit, of which it requires 254,000,500 to make one inch, are used in spectrum analysis for measuring the dimensions

of light waves, while on the other hand the "earth's orbit" (meaning the mean radius of the orbit) is used by astronomers in measuring stellar distances. In addition, the "light-year" is used for the greatest distances, this unit being the distance which light traverses in one year, or about 6,000,000,000,000 miles. With the extension and division in size of units, the kinds of instruments utilized, and methods of application of the units themselves, have multiplied. Almost every occupation has its particular units, its methods of making measurements, and its special measuring instruments. A few of the thousands of the latter may be cited, such as the common desk rulers, carpenter's folding rules, draughtsman's scales, surveyor's chains, engineer's tapes and level rods, lumberman's log rules and board measures, the merchant's yard stick, the tailor's tape, the shoe, glove and hat measures, machinist's scales, measuring bars, micrometers, micrometer calipers, limit gauges of ring and plug types, end and line standards of precision. In measuring volume we have the standard capacity measures, wooden dry measures, a vast variety of standard flasks, glass graduates such as burettes, pipettes and other volumetric apparatus of the druggist, physicist and chemist, the gauging rods for casks and cargoes, gasoline measuring pumps, gasometers reading in cubic feet, tanks and reservoirs with graduated scales reading volumes directly. For weighing, we have even-balance scales, steelyards platform scales, spring balances, all ranging from the most delicate analytical balances to the master scales for weighing freight cars. Scales are especially designed for every particular need, and the countless varieties attest the high state of the art of weighing and its great importance in industrial and scientific work. Such instruments have multiplied in form and number, and the demand for them has grown so rapidly that the manufacture of weights, measures and measuring instruments forms in itself a whole group of industries.

With the development of units of measure of the order of intermolecular distances on the one hand and of almost interstellar distances on the other, and the multiplication of kinds of instruments used in measurement, has come the invention of a large variety of measuring appliances which automatically indicate the result upon a scale. Of this class are thermometers, spring balances, aneroid barometers, pressure gauges, speedometers, and indicating meters of all kinds. Computing scales not only indicate the weight, but show the computed total price of the article at several prices per pound. Many of this class of instruments also make continuous record of the measurements, showing by a curve the values at successive moments of time. Of this type are the automatic recording instruments used to record temperature, air pressure, sunshine, rainfall, electrical quantities as well as tide recorders, anemometers and many others. Equally interesting are those measuring instruments like dividing engines, trip scales or trip measures which besides measuring definite lengths, weights or quantities automatically perform certain operations, such as graduating a scale, delivering or tipping a certain weight of grain, or delivering certain volumes of liquids. Closely related are those devices which integrate quantities delivered or magnitudes measured, such as the small map wheels which measure distances on maps, or the planimeters which measure areas within irregular contours, and all forms of gas and water meters, integrating rain gauges, integrating watt meters for measuring electric power consumed. These instruments usually indicate on a dial the total number of units measured since the last zero setting.

Metrology.—Many sciences and industries have given the science of metrology their best thought and labors. Chemistry opened up new chapters in the science of the refractory metals, developing iridium and platinum of purity requisite for the world's fundamental standards of mass and length, producing in conjunction with metallurgy the remarkable nickel-steel alloy "invar" (q.v.), having practically a zero temperature coefficient of expansion; the alloy manganin, free from temperature coefficient for electrical resistance; Jena glass, a material for measuring flasks and thermometer bulbs which practically eliminates temperature disturbances. To optics and the glass industry we are indebted for the microscopes, telescopes, polariscopes and other optical instruments which form essential parts of modern measuring apparatus. Optical methods based upon the interference of light waves have made possible the detection of change of dimension far beyond the power of the microscope to detect. By such methods plane surfaces are produced having errors of less than a millionth of an inch, and in the interferometer is provided one of the most delicate and sensitive length-measuring instruments known to man. Metallurgy and engineering have developed methods of fusing, casting and tempering materials to be used in measuring apparatus, and have developed the accurate machining of such instruments. Astronomy has given the precision measurements of time, the "second" being the unit of time in the international C. G. S. system of units. Mathematics has devoted a large section of its science to the theory of observations and added rigor in their adjustment, and in the elimination of accidental errors, and by developing the theoretical side of precision measurements has rendered the greatest service to metrology.

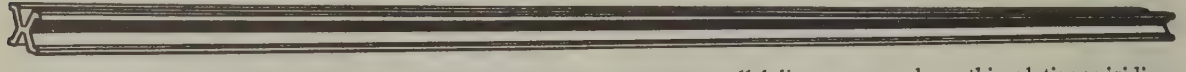
Unit Standards.—The standards of length and mass are fundamental. From these and the unit of time practically all other standards are derived, either directly or indirectly. The derived standards include those used in the measurement of volume, density, capacity, velocity, pressure, energy, electricity, temperature, illumination, and the like. The production of copies, multiples and subdivisions of the fundamental standards, the construction of the derived standards, and the comparison of the standards used in scientific work, manufacturing, and commerce, with the fundamental or derived standards of the government, are functions of the National Bureau of Standards in the United States and of similar bureaus in other countries. In the United States the standard of the weights and measures of trade is maintained through the state, county and city sealers of weights and measures with an efficiency dependent upon local administration. For more precise purposes, however, uniformity and precision are attained and maintained only by regular reference of the local standards to the fundamental standards of the government, at the National Bureau of Standards in Washington.

The units of weight and measure in the United States are practically those used in the colonies prior to the formation of our government. While Congress has never definitely authorized the

weights and measures in common use, it has sanctioned their use by its act of June 14, 1836, providing that accurate copies of the yard, pound, etc., be furnished as standards to each state of the union. The constitutional power "to fix the standard of weights and measures," vested in Congress (I. 3, ¶ 5, United States Constitution), has rarely been exercised, so that legislation on weights and measures has been confined to the individual states, and in this manner numerous differences in usage grew up in the several states, although the same general system of weights and measures prevails throughout the country. The customary units of length are defined by reference to the yard. The yard itself was formerly defined as the length of a certain bronze bar, the standard yard, kept at the Office of Standard Weights and Measures in Washington. Since 1893 the yard is defined in terms of the international meter. The yard appears to have been a unit of length in England since very early times. The name signified in Old English and in Anglo-Saxon (gyrd) a rod or stick. A standard bronze yard of 1496 still exists in England, having been used for the verification of other yards until 1588, when a new standard was made which is also in existence today. This yard, known as the Winchester standard, was the legal standard in England until 1824, when new standards, the imperial standards, were authorized.

When the Coast and Geodetic Survey was organized it was found necessary to have a definite standard of length, and an 82-inch bar was secured from the instrument maker, Troughton, of London. This bar was nearly a copy of Troughton's scale, and had not been compared with the British standard yard, but the distance between the 27th and 63d inch marks on the bar was taken as representing the standard yard, and was made the basis of the standards sent out in accordance with the act of Congress of 1836. In 1834 the British imperial yard was destroyed by fire and when a new standard had been prepared, copies of it were made, two of which were presented to the United States in 1856. These copies were compared with the Troughton scale, and the latter was found to be 0.00087 inch longer than the new imperial yard at the standard temperature of 62°F. One of the copies was then accepted as standard by the United States Office of Standard Weights and Measures in place of the Troughton scale. This copy of the imperial yard was the standard on which all measurements of length in the United States were thereafter based until 1893, when the yard was defined in terms of the international prototype meter. The matter had been left entirely to the treasury department, which had adopted different yards from time to time, assumed to be equal to the British imperial yard.

The copies of the imperial yard had shown noticeable changes relative to the standard when subsequently compared, and this led to the belief that the imperial yard itself was not constant. Shortly after the arrival of the national prototype meter a careful determination of the relation of the imperial yard to the international meter at the Office of Standard Weights and Measures showed that the relation differed from that legalized in 1866 by less than the uncertainty of the comparison, and it was decided to adopt the meter as the fundamental standard of length, and to define the yard in terms of it. Not only is the constancy of the length of the imperial yard suspected, but in addition the lines, which are about 1-1000 of an inch wide, are much too broad for present requirements. On the other hand, the international meter and its copies satisfy the rigorous requirements of modern metrology. The kilogram was also declared to be the fundamental standard of weight. The present standards of the United States are, therefore, independent of the British standards and in part differ from them. The prevalent idea that the weights and measures in common use are identical with the British imperial system is, therefore, erroneous. The United States yard is longer than the imperial yard by about one part in 300,000, and this inequality extends to all of its subdivisions and multiples. The present material standards of the United States are the national prototype meter No. 27 and the national prototype kilogram No. 20, received by the president of the United States on Jan. 2, 1890. These are accurate copies of the international prototype meter and kilogram which are the fundamental standards of length and weight designed for the entire world. The latter standards are preserved at the International Bureau of Weights and Measures in accordance with the International Metric Convention of 1875, now signed by the leading countries of the world. These countries jointly maintain and direct the work of this bureau through official representatives forming an international committee, composed of eminent scientific men.



The National Standard of Length. The distance between two parallel lines engraved on this platinum-iridium bar kept at the National Bureau of Standards is the primary standard meter for all metric measurements of length in the United States. It is Prototype No. 27 of the international standard kept at the International Bureau of Weights and Measures at Sèvres, France. This national standard of length, far from being just a museum item, functions actively as a fundamental reference and control in commerce and industry. Laboratory and industrial meter bars are checked against "working standards" of length, which, in turn, are compared at intervals with the standard meter.

The units of length and the derived units of area, volume and capacity are derived from the international meter in the ratio of 1 meter = 39.37 inches (law of July 28, 1866). Since 1893 the Office of Standard Weights and Measures and the National Bureau of Standards which superseded that office, have used the equivalent 1 yard = 3600/3937 meter (by order approved April 5, 1893). This action fixed the values, inasmuch as the reference standards are as perfect and unalterable as human skill could make them. Besides the yard, the units of length most universally employed in the United States at the present time are the inch, foot, and mile.

An inch-millimeter conversion for industrial use, in which 1 inch = 25.4 millimeters, has been adopted by the American Standards Association, and by similar standards associations in a large number of countries. This relationship is numerically between the official relationships used in the United States, and that in Great Britain.

The "inch" is the 1–36 part of the yard and

like it has been in use since ancient times. The name (derived from the Latin *uncia,* meaning the 12th part) occurs in Anglo-Saxon in the form of "ynce." It probably originated only as a convenient subdivision for the foot. Lengths shorter than one inch are commonly expressed in fractions of an inch. Two methods of subdivision are in common use; among builders and woodworkers it is customary to use the binary subdivisions, half, quarter, eighth, etc., but machinists also divide the inch into tenths, hundredths, and thousandths. The inch is usually denoted by the symbol ″; but botanists use the symbol ′ for the inch. The "miner's inch" is a rather vague unit for the flow of water varying from 1.36 to 1.73 cubic feet per minute, and is the flow of water through a single square inch of orifice under varying heads of water.

The "foot" is legally defined as one third of the yard, or 12 inches. As its name implies, it was probably based on the length of the human foot. Almost every nation, ancient and modern, has had a unit called the "foot," its value differing somewhat, as might be expected with a unit of so crude an origin. Most countries, however, have now adopted the metric system, the foot being discarded as an official measure, though universally used in English countries. Lengths shorter than one foot are usually expressed in inches and fractions of an inch, but among surveyors and civil engineers it is quite common to use decimal fractions of the foot. The foot is generally denoted by the symbol ′, but botanists use the symbol ° to denote feet. Some artisans use the foot and the inch but not the yard, others the yard and its binary divisions, but not the foot or inch. Thus the foot and inch are used to the exclusion of the yard in building, while the yard and its binary subdivisions to the exclusion of the foot and inch in measuring cloth.

The "statute" or "land mile," is the unit most commonly used for longer distances, and is equal to 5,280 feet. The name is from the Latin *mille passuum,* 1,000 paces, the Roman pace being a double step and consequently about five feet in length. This mile was used by the Anglo-Saxons. Almost every European nation has had a unit called the "mile," but widely at variance with one another, ranging from about two-thirds of the United States mile (Holland) up to seven United States miles (Norway). The old British statute mile was about 300 feet shorter than the United States mile but the present British unit is practically the same as that of the United States.

The following units of length are used in special work and are arranged in the order of their magnitude. Metric units are not included, as they are for the most part official only, and not generally in use in commercial and industrial activities in Anglo-Saxon countries. They are commonly used in a larger part of the world.

Mil (.001 inch) is used in electrical work, especially in indicating the cross section of wires.

The point (approximately 1–72 inch) is used in designating the sizes of type, the point system designating the sizes of type by the number of seventy-seconds of an inch height of the type face. The em is a unit of measure used in composition and varies with the size of the type, usually being considered as the square of the face height.

The line (1–12 inch) is little used, mechanics preferring to divide the inch into tenths, hundredths and thousandths. It is used by printers and by botanists, the latter denoting the line by the symbol ‴. The line "button measure" is 1–40 inch as defined in the tariff act.

The barleycorn (one-third inch) is an old unit still surviving in shoemakers' shoe sizes, these being graded by thirds of an inch or barleycorns, in a system of 13s.

Four units based upon the "hand" are sometimes used. These are the nail (two and one-fourth inches) for measuring cloth, originally the distance from the end of the thumb nail to the joint at the base of the thumb, and later fixed as 1–16 yard; the palm (three inches) includes the breadth of the hand exclusive of the thumb; the hand (four inches), originally the breadth of the palm, is used in measuring horses and is almost exactly one decimeter; the finger (four and one-half inches) is about the length of the middle finger and is only used as a rough unit in cloth measure. This should not be confused with the finger breadth used in measuring charges of powder.

The surveyor's link (7.92 inches) is the length of one link or 1–100 part of a surveyor's chain, and is used in the survey of lands.

Quarter (nine inches) is sometimes used in measuring cloth (more frequently in Great Britain) to designate a quarter of a yard. A unit of the same length called the span was originally half a cubit, but probably has not been used in modern times as an officially recognized unit.

The engineers' link (12 inches) used as a unit in engineering is the hundredth part of the engineers' chain and is decimally divided. The 10th of the engineers' link is 1.2 inches.

The pace is a conventional unit for measuring distances and is the length of a stride measured from the heel of one foot to that of the other; a full pace measures about one yard. This is the value of the United States military pace, double time, with a cadence of three steps a second. The regulation military pace quick time is 30 inches with a cadence of approximately two steps per second. The Roman pace was a double step of about five feet.

The English ell, a unit still referred to but seldom used, had a value of 45 inches, varying, however, in different places. The Flemish ell of 27 inches was in common use in the Low Countries.

The fathom (six feet) is used in measuring depths of water or mines. The name comes from an Anglo-Saxon word *faethm,* signifying "embrace," and originally meant the length of rope between the two hands when the arms were held outstretched.

The rod, perch, or pole is equal to five and one-half yards and is used in measuring land. It has varied in different places from five to eight yards and is supposed to have been the length of the ancient goad used to measure the width of the first furrow.

The surveyor's or Gunter's chain (22 yards) was so chosen that 10 chains square might exactly equal one acre. This chain is the official unit prescribed formerly for the use of surveyors surveying public lands under the supervision of the surveyor general and now often used in relocating old surveys.

The engineers' chain (100 feet) is used in engineering, and is decimally divided into feet, tenths, and hundredths of a foot. The use of

the two chains in many cases for the same land for different purposes requires reduction tables. On account of the direct relation to the foot, the engineers' chain is becoming very widely used; measurements being expressed in feet and decimals of a foot.

The bolt for measuring cloth is generally given as 40 yards, though the name means simply a roll of definite length. The customary length of the bolt varies with different fabrics and manufacturers.

The skein for yarn is often defined as 120 yards. Its length varies, however, according to the material and the locality.

The United States cable's length (720 feet), used by mariners, is 120 fathoms as recognized by the United States Navy.

The furlong (220 yards) originally meant "length of a furrow," supposed to be the distance oxen could plow without stopping to rest.

The hank is a unit of length for yarn. In the United States the length of a hank of cotton is usually 840 yards, while that of linen is 3,000 yards; different lengths, however, are also in use under that title.

The nautical mile or geographical mile has been defined as 1–60 part of the length of a degree of a great circle of the earth. Since the earth is not a perfect sphere, however, the degree varies in length and this has led to much confusion in usage regarding the nautical mile. The definition accepted by the United States Coast and Geodetic Survey (consult Report of 1881, Appendix 12) is as follows: The 1–60 part of the length of a degree on the great circle of a sphere whose surface is equal to the surface of the earth. This makes the length of the nautical mile 6,080.20 feet or 1,853.248 meters. The uncertainty in the dimensions of the earth affects the last decimal place given. The nautical mile is often miscalled "knot." The latter term, however, is not a measure of length, but a measure of speed, equal to one nautical mile per hour. The admiralty "knot" of Great Britain is 6,080 feet per hour.

The league is equal to three miles, the land league being equal to three United States statute miles (15,840 feet) and the United States marine league to three nautical miles (18,240.6 feet). Its value varies in different countries. The marine league is the distance from shore over which a country has jurisdiction under international law.

A degree of the earth's meridian, or of the circumference at the equator, is very nearly equal to 60 nautical miles.

The astronomical unit, equal to the mean radius of the earth's orbit or nearly 93,000,000 miles, is sometimes used in stating astronomical distances.

In stating interstellar distances it is sometimes found convenient by astronomers to use the light year, being the distance traversed by light in one year, or 64,600 astronomical units.

Besides the measures of length given above, there are numerous very special methods of denoting length in case of special commodities. The thickness of sheet iron and steel is denoted by a system of arbitrary gauge numbers. The numbers in use differ for different products. On March 3, 1893 Congress passed an act establishing a standard gauge for sheet and plate iron and steel for use in the customs service. In this system the gauge numbers indicate thickness, or the weight per unit area. Sizes of wire are also denoted by a special system of arbitrary gauge numbers. The number of different systems which have been used is quite large. Pfeilschmidt's *Wire and Sheet Gauges of the World* gives comparative tables for 11 systems of wire gauges. At present the most common gauges in use in this country are the Brown and Sharpe gauge and the Birmingham wire gauge. (See WIRE.) The fineness or coarseness of yarn is denoted by a system of numbers, called "counts," which indicate usually the number of hanks of the yarn in question which will weigh one pound. Thus No. 10 yarn (English cotton yarn and spun silk count) is a yarn of such fineness that 10 hanks (of 84,000 yards) are required to make a weight of one pound, or again No. 1 wool (Aberdeen count) is such that one spindle (of 14,400 yards) shall weigh a pound. There are about 24 different systems of counts in use, and in order to introduce uniformity in counting textile yarn throughout the world, the international metric count was approved by the International Paris Conference of 1900. According to this count, No. 1 means that a length of 1 meter will weigh 1 gram, and 100 meters of No. 100 yarn will weigh 1 gram. The grex system of yarn numbering developed from this, a grex unit being equal to the weight in grams of 10,000 meters of yarn or other material.

In addition to the above there are a large number of special systems of numbering particular commodities such as hats, shoes, gloves, nails, cordage, books, and other articles too numerous for description.

The units of superficial measure or area are usually the squares of the linear units and as such need but little comment. The circular mil (.7854 square mil) is the area of a circle .001 inch in diameter. One circular inch contains 1,000,000 circular mils, and one square inch contains 1,273,240 circular mils. The square inch is the most common small unit of area, being used in measuring pressures, strength and other properties of materials, and in engraving, cloth analysis and many other purposes. The square foot (144 square inches) is also largely used. It is the basis of the board foot which is 144 cubic inches of undressed lumber, being reckoned as one square foot of one inch board, or its equivalent. The "square" is a unit used in carpentry for flooring, ceiling, and shingling, and contains 100 square feet, architects' and builders' measure.

In surveyors' measure 1 acre = 10 square chains = 160 square poles = 100,000 square Gunter's or surveyors' links. The acre (43,560 square feet) was probably as much land as could be tilled in a day and therefore of rather indefinite extent until later times. It is a unit of the same order as the French *journée* and the German *Morgen*. The acres of various countries differ in size, for example, the Irish acre of 7,840 square yards; the Scottish acre of 6,104 square yards; the Cheshire acre of 10,240 square yards; Cunningham acre and the Imperial acre.

In subdividing public lands in the United States, the lands are laid out in townships. One township = 36 sections or square miles = 144 quarter sections = 23,040 acres. The "homestead" is a free grant of public land having a maximum area of one-quarter section or 160 acres. In the Philippine Islands, the "homestead" is 64 hectares, which is almost identical with the homestead as defined above.

Among the more important units of volume

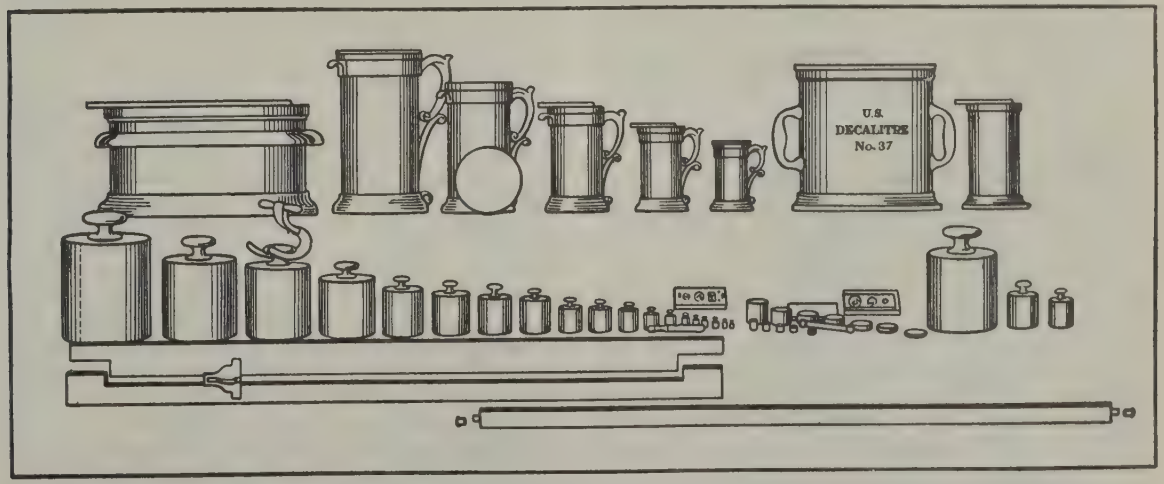
are the cubic inch, the cubic foot, the cubic yard, and the cubic mile. The cubic inch is practically the smallest unit of volume based directly on linear units. It is very largely used. The cubic foot (1,728 cubic inches) is used in engineering to express volumes of gas, water, or other solids. In some states, such as Washington and Colorado, the cubic foot is established by statute as the legal unit for measuring the volume of water. A special system of units is used in the measurement of wood; 144 cubic inches or one foot square of one inch board is expressed as one board foot. A timber foot, however, is 1,728 cubic inches or one cubic foot. A cord foot is a pile of wood 1 by 4 by 4 feet. In the absence of state laws to the contrary a cord of wood is 128 cubic feet. In the lumber business, boards are usually bought and sold by the 1,000 board feet to simplify computation. In New Hampshire, a measure for lumber was adopted in 1866 based upon an "imaginary cubic foot" equal to about 1.4 cubic feet. This unit is also used in parts of Maine and Vermont. Round timber is measured as follows: "A stick of timber 16 inches in diameter and 12 inches in length shall constitute one cubic foot, and the same ratio shall apply to any other size and quantity. Each cubic foot shall constitute 10 feet of 1,000 board feet." In the practical use of this rule it is customary to consider 115 cubic feet equivalent to 1,000 board feet, instead of 100 cubic feet, according to the wording of the statute. In this case the diameter is taken at the middle of the log inside the bark. If the diameter is measured at the small end of the log, 106 cubic feet are allowed for 1,000 board feet. The New Hampshire rule is called the Blodgett Rule. Several log rules are specified by state law or have some currency. The International Log Rule is specified by more states than any other. By it the number of board feet is computed for 4-foot sections, by the use of a formula. Tables have been prepared to eliminate much of the computation. The cubic yard is used largely in engineering and in computing grading, cuts and fills, a cubic yard being equal to about one load.

The perch, in addition to being a unit of length and a unit of area, is also widely used as a unit of volume of brickwork and masonry. The perch of masonry, however, is a widely varying unit, ranging from 16½ cubic feet to 25 cubic feet. In Colorado it is 16½ cubic feet, 25 cubic feet in North and South Dakota, 24¾ cubic feet in Delaware. The latter perch is equal to a section of brickwork 1 by 1½ feet by 16½ feet, or one perch in length.

A cord of masonry is usually reckoned at 100 cubic feet, although in some cases it is 96 cubic feet.

The cubic mile is used in expressing very large volumes, such as the silt carried by rivers.

Liquid Measure.—The fundamental unit of liquid measures in the United States is the wine gallon of 231 cubic inches—a unit abandoned by England in 1824, but now generally adopted by the various states of the Union. The British imperial gallon measures 277.42 cubic inches, and is the volume of 10 pounds of water at 62°F. The liquid measures of the United States unfortunately bear no relation to those of England. As late as the first part of the 20th century there was confusion caused by the use in the United States of gallons other than the gallon of 231 cubic inches. The ale, beer, or milk gallon, as it was variously termed (282 cubic inches), was most often encountered. But annual conferences on weights and measures, beginning in 1905, have done much to unify the laws on weights and measures in the several states, including the elimination of the ale, beer, or milk gallon. The ordinary liquid measures are usually 1 gallon = 4 quarts = 8 pints = 32 gills. The "proof gallon" is a wine gallon of spirits containing one half its volume of nearly pure alcohol at 60°F., and is the basis for computing the United States internal revenue tax. For example, a gallon of spirits containing 40 per cent alcohol would be 80 per cent proof, and the number of proof gallons is computed by multiplying the per cent of proof by the number of wine gallons. In addition to the capacity measurement by volume, the legal weight of a gallon of certain commodities has been fixed by statute in some states. The wording of these statutes differs: in some cases they define the purity of the product, in others they provide for the sale by weight, retaining the trade usage of the term gallon. Examples are 6½ pounds of kerosene in Kansas, 8 pounds of castor oil in Kansas, 11 pounds of sorghum molasses in Indiana, and 11 pounds of maple sirup in Ohio.



This complete set of standards of capacity (top row), mass (center), and length (below) is calibrated by the National Bureau of Standards in terms of the national standards and furnished to each of the states for use in regulation of weights and measures. The state standards are returned periodically to the bureau for recomparison.

The subdivisions of the gallon, the quart, pint, and gill are largely used in trade. In addition to the general liquid measures enumerated above, apothecaries have a special system of capacity measures based on the volume of the United States liquid pint of 28.875 cubic inches. One pint = 16 United States fluid ounces = 128 United States fluid drams = 7,680 United States minims.

The minim is the smallest of the United States units of volume and is about 0.00376 cubic inches. A minim of pure water weighs about 0.95 grains and corresponds to the "drop," which it approximates in size. The United States minim is about 4 per cent larger than the British Imperial minim. It is denoted by the symbol ♏.

The drop varies from 0.02 to 0.1 cubic centimeter and is not a fixed unit, but is convenient for use in dispensing very small quantities of liquids. It is not subdivided and its size depends upon the liquid and the method of dropping. The ordinary form of drop pipette of the ophthalmologist delivers drops of about a half United States minim.

The United States fluid dram (60 minims), is equal to one-eighth United States fluid ounce, its volume differing from the volume of one avoirdupois dram of water, from the volume of one apothecaries' dram of water (by weight), and is about 4 per cent larger than the fluid dram in use in Great Britain. It is about 4 cubic centimeters, or an average teaspoonful, and is denoted by the symbol ƒ3.

The United States fluid ounce (480 United States minims) is the 1–16 part of the wine pint and has a volume of about 1.8 cubic inches. It differs from the British unit of the same name as well as from the volume of the avoirdupois ounce of water and the troy or apothecaries' ounce of water. Other measures of less definite character are often found convenient, such as the teaspoonful, dessertspoonful, tablespoonful, wineglassful and teacupful. The spoons used as culinary measures contain the following quantities: a tablespoon, 4 fluid drams or 15 cubic centimeters; a teaspoon, 1⅓ fluid drams or 5 cubic centimeters.

Dry Measures.—The dry measures in general use in the United States bear no direct relation to the liquid measures of the United States or Great Britain. The following are the ordinary units of dry measures: one bushel = 4 pecks = 32 dry quarts = 64 dry pints. The fundamental unit is the Winchester bushel, a unit abandoned by England in 1824. The Winchester bushel had a capacity of 2,178 cubic inches. In the United States the name Winchester has been attached to the London bushel with a volume of 2,150.42 cubic inches and is about 69 cubic inches or 3 per cent smaller than the Imperial bushel of Great Britain—a proportionate difference existing in the subdivisions of the bushel.

During the 19th century there was considerable confusion because of the variance in state laws giving special definitions of bushels for specific purposes. Most of these have been repealed. But in Connecticut, Delaware, Maryland, Michigan, and Oklahoma, the charcoal bushel is defined as 2,748 cubic inches, in Colorado it is defined as 2,500 cubic inches, and in Missouri and Oklahoma as 2,680 cubic inches. In Vermont the law reads that "one bushel and three-quarters of a peck shall be deemed a bushel of limes or ashes." Besides the usual "struck bushel" there is also the "heaped bushel," required in some states to be "as high as the article will admit," and elsewhere "as high as may be without special effort or design," but being specifically stated in Connecticut as 2,564 cubic inches.

The many objections to buying and selling agricultural products by volume, such as the difficulty of detecting error or fraud, the variation in the size of the heap, the ease of packing short quantity in a given volume, the effects of expansion, moisture, or shaking, and the general uncertainty of estimates of quantity based upon volume, early led to the practice now quite general, of defining the bushels as definite weights for the different commodities. Unfortunately the matter was left to the several states with the result that the lack of uniformity in legislation and custom has introduced some confusion. In most cases these laws do not define bushels as units of measure, but rather provide for selling specific products by weight, retaining the trade practice of stating quantities in terms of "bushels." Although this may seem to be a source of confusion in compiling accurate statistics because of the use of a term that is variable, there is no more confusion than if the bushel of 2,150.42 cubic inches were used and such items as degree of filling, amount of shaking down, and subsequent refilling, were variables. Obviously statistics by weight for agricultural products would have much merit.

The barrel is a convenient receptacle for packing, transporting, and storing commodities. It has also long been used as a unit of measure. As these containers varied in size, so has the barrel as a unit varied. In at least one instance it is defined in terms of units of volume, the apple barrel in Massachusetts being 7,056 cubic inches. In many states it is defined in gallons, being 42 gallons for all liquids in Tennessee, 31 gallons for beer and other malt liquors in New York; the most usual quantity is 31½ gallons. As in the case of gallons and bushels, the weight of some products has been specified by state laws for selling by weight under the term barrel. Probably the most common example of this was the flour barrel of 196 pounds; but the practice arose of selling flour in bags or sacks containing simple fractions of 200 pounds, and this practice became universal in the United States during World War II. Not as many products have been specified by weight per barrel as in the analogous cases of the gallon and bushel. However, 200 pounds of shelled corn constitute a barrel in Maryland and the District of Columbia, 200 pounds of pork in Ohio, and several other states, 150 pounds of potatoes in Connecticut, 200 pounds of corn meal in Wisconsin, and 200 pounds of fish in a number of states including Ohio. In some states the dimensions of the barrel are specified; thus the cranberry barrel in Massachusetts is required to be not less than 25¼ inches between the heads, length of staves 28½ inches, diameter of head not less than 16¼ inches including beveled edges, outside bulge circumference not less than 58 inches, and thickness of staves not greater than four tenths of an inch. In the petroleum industry a 42-gallon barrel is commonly used for statistical purposes.

The hogshead (two barrels), the pipe (four barrels), and the tun (eight barrels) are more commonly not intended as definite measures but merely convenient receptacles for liquids in bulk.

TABLE SHOWING IMPORTANT UNITS OF WEIGHTS AND MEASURES AND THEIR EQUIVALENTS IN UNITED STATES UNITS[1]

Name	Country	United States Equivalent

[1] The metric system is in general use throughout the civilized world except in Anglo-Saxon countries. In Latin American countries many of the old Spanish and Portuguese units have considerable use. References are occasionally found to old units in European and Asiatic countries. In some cases the units do not have a precise value, and some units are spelled differently in English by different authorities.

The smaller units of dry measure, such as the peck, dry quart and dry pint, are largely used in retail trade, the pint and quart being used for smaller products like berries.

Avoirdupois System.—The avoirdupois system of weights is used for almost all commodities except the precious metals and jewels. The avoirdupois dram differs from the apothecaries' dram, and the avoirdupois ounce and pound differ from the troy units of the same name. Ambiguity is avoided only by properly qualifying the terms. The use of such unqualified terms as ounce, pound or ton causes great confusion owing to the uncertainty and ambiguity of the terms. The "avoirdupois pound" or "troy ounce," however, are definite units. The avoirdupois units are as follows:

One long ton = 20 long hundredweights = 80 long quarters = 2,240 pounds = 35,840 ounces = 573,440 drams = 15,680,000 grains.

One short ton = 20 short hundredweights = 80 short quarters = 2,000 pounds = 32,000 ounces = 512,000 drams = 14,000,000 grains.

The fundamental unit of the avoirdupois system is the avoirdupois pound now derived from the International kilogram, in accordance with the law of 1866 and the executive order of 1893, the value being 453.5924277 grams. It is a matter of controversy as to the time the avoirdupois and troy pounds were introduced into England. The earliest mention in law of the troy pound is in 1414. The earliest mention of avoirdupois is 1335. Congress has never directly legalized any standard of weight except the troy pound and that only for purposes of coinage. To avoid confusion in comparisons of mass, the ratio of the avoirdupois pound to the troy pound was fixed at 7,000 to 5,760, measured in grains.

The United States avoirdupois dram (or drachm) is the 1/16 part of the avoirdupois ounce (28.3495 grams). This unit must not be confused with the apothecaries' dram (weight) which is the 1/8 part of the apothecaries' ounce or 60 grains. The avoirdupois dram is largely used in the textile industries. The avoirdupois ounce is the 1/16 part of the pound and contains 16 drams. The avoirdupois stone is a denomination often used in England, and varies with different commodities, the most common value being fixed in England as 14 pounds.

The hundred weight (cwt.) is the 1/20th part of the ton. In the United States, Canada, and South Africa it is 100 pounds; in Great Britain it is 112 pounds.

The short ton of 2,000 pounds is generally used in the United States, Canada, and South Africa; in Great Britain the long ton of 2,240 pounds is required. In comparing statistics one must be sure of the ton used in each case. Besides the short ton and the long ton there is the metric ton (approximately 2,246 pounds) and also several special tons, as, for example, the displacement ton of 35 cubic feet, the shipping ton of 40 cubic feet, the timber ton of 42 cubic feet, and the register ton of 100 cubic feet. When a ton of hay is sold by measurement rather than by weighing in certain states, the number of cubic feet to be considered equal to a ton is specified, thus 343 cubic feet in North Dakota and Ohio, and 380, 422, or 512 cubic feet in New Mexico, according to the time that the hay has been stacked.

Troy Weights.—The troy weights are as follows: one pound = 12 ounces = 240 pennyweights = 5,760 grains. The troy pound was legalized in 1828 as the standard unit to be used by the mint of the United States in the regulation of the coinage. In view of the confusion in the weights and measures of trade, Congress found it important to legalize some particular weight for the use of the mint, and by the act of May 19, 1828, legalized the copy of the Imperial Standard troy pound. This copy was procured by Albert Gallatin in England in the preceding year and was received by President John Adams Oct. 13, 1827. It was based upon the old Imperial Standard troy pound of 1758, legalized in 1825. This troy pound has not been recognized as a legal standard in England since 1855, and was declared illegal, with penalty attached, in 1878.

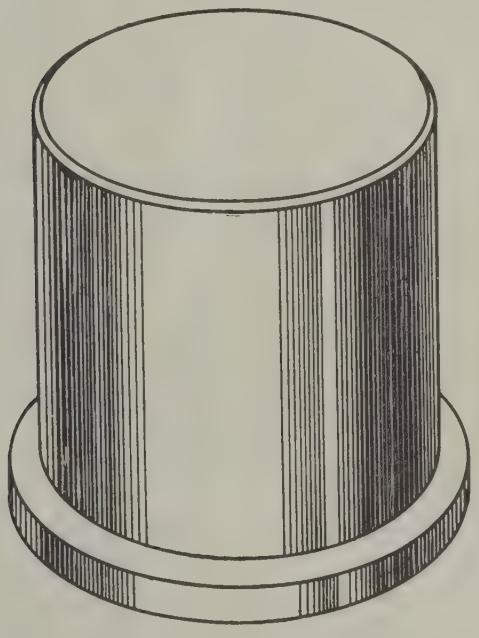
The grain is the 1–5,760 part of the troy pound, and is the only unit which is identical in the troy, apothecaries', and avoirdupois systems. A very old English statute (51 Henry III, 1266)

provided that the English penny should weigh "thirty-two grains of wheat well dried and gathered out of the middle of the ear." The grain has been used as a unit of weight in many countries, but with varying values from 0.68 to 1.54 United States grains. The grain, as used in the United States, is 0.0648 gram.

The pennyweight is the 1–240 part of the troy pound.

The troy ounce is used in stating the quantities of silver and other precious metals. In England it is the highest unit used in the troy system. In assays, the troy ounce is frequently divided decimally. One hundred seventy five troy ounces equal 192 avoirdupois ounces.

Apothecaries' Weights.—The units of apothecaries' weights are as follows: one apothecaries' pound = 12 ounces = 96 drams = 288 scruples = 5,760 grains. The apothecaries' pound is equivalent to the troy pound in the United States, but in England the apothecaries' weights were discontinued in 1858 under authority of the medical act, and avoirdupois weights substituted in dispensing medicines. In the United States, although the metric system is gaining in use for dispensing medicines, the apothecaries' weights are still used: the grain, the scruple (20 grains), the dram (60 grains), and the ounce (480 grains). The apothecaries' pound (equal to the troy pound) is rarely used.



The national standard of mass, known as Prototype Kilogram No. 20, is a platinum-iridium cylinder 39 mm in diameter and 39 mm high. It is an accurate copy of the international standard kept at the International Bureau of Weights and Measures at Sèvres, France. Prototype No. 20 was furnished the United States by the International Bureau in accordance with the metric treaty of 1875. Recomparison with the international standard in 1937 showed that the United States standard has remained constant within one part in 50 million during approximately 50 years.

Metric Carat.—The basic unit used in the weighing of diamonds is the metric carat of 200 milligrams. This was adopted by the United States in 1913 and has been adopted practically universally throughout the world. The so-called international carat of 205 milligrams, used before the adoption of the metric carat, was very nearly the value of the old English carat. The metric carat is divided decimally. Another mode of division is into four diamond grains, sometimes referred to as carat grains, and each of these grains is then subdivided into 16 parts. The term carat is derived from the name of a small, hard bean, formerly used to weigh diamonds. The carat used in weighing diamonds is quite different from carats as used to define the purity of gold alloys, a carat in that case being one part of gold in 24 of the alloy.

Metric System.—The metric system is in general use in most of the non-English speaking countries of the world. But in the British Commonwealth of Nations and in the United States the use of the metric system is largely restricted to scientific work. In the United States the use of the metric system was made legal for all purposes in 1866. Scientists have universally adopted the metric system because their results are then readily comparable with similar results obtained in other countries and because of the advantages of the decimal character of the units. The basic units of the metric system are the meter for length and the gram for mass (weight). The primary standards, a meter bar and a kilogram (1,000 grams), are kept in a suburb of Paris, France, but copies have been distributed to the principal countries of the world. The liter is the metric unit of capacity corresponding to the volume of water weighing one kilogram under specified conditions. For most practical purposes the liter can be considered as equal to the volume of a cube one tenth of a meter (one decimeter) on a side. See also BALANCE; METRIC SYSTEM; TONNAGE; WEIGHING MACHINES.

Revised by: LEWIS V. JUDSON,
Chief of Length Section; National Bureau of Standards, Washington, D.C.

WEIHAIWEI, wā'hī'wā', seaport, China, former British naval and coaling station, in the province of Shantung, near the eastern extremity of the Shantung Peninsula, 40 miles east of Chefoo. It lies on the south shore of the entrance to the Gulf of Pechili, opposite Port Arthur on the north shore, about 100 miles distant. During the Sino-Japanese War, the Japanese destroyed a Chinese fleet here and captured the town, which they evacuated early in 1898. By a convention of July 1, 1898 the port of Weihaiwei, together with the adjacent waters and some neighboring

territory, was leased to Great Britain. The leased territory included the island of Liu Kung, all the islands in the bay and a belt of land 10 miles wide along the whole coast of the bay; area, 285 square miles; pop. 154,416; but the population of the town of Weihaiwei is only about 2,500 inhabitants, being an old-time walled town. By the terms of the lease Great Britain had sole jurisdiction within the limits of this territory, but within the walls of the city, Chinese officials might exercise such authority as was not inconsistent with the defense of the territory. The British government could also erect fortifications and carry out other defensive works in a defined region lying outside of the leased territory. Chinese war-vessels retained the right to use the waters. Weihaiwei was not to be fortified, but was used as a flying naval base and place of exercise and sanatorium for the China squadron. As a result of the Shantung settlement at Washington in 1922 England offered to return Weihaiwei to China on certain terms which China accepted but the unsettled condition of the country hindered progress in carrying out these plans and Great Britain remained in possession of Weihaiwei until Oct. 1, 1930, when she formally handed it back to China. The chief imports are piece goods, raw cotton and yarn, oil, rice, flour, and tobacco; the exports are ground-nut oil, ground-nuts, eggs and sugar. There is weekly mail service to Shanghai and Europeans visit the place in summer because its climate is the best in the Far East. Consult Annual Report on Weihaiwei; Bruce-Mitford, C. E., *The Territory of Weihaiwei* (1902); Johnston, R. F., *Lion and Dragon* (London 1910).

WEIMAR, vī'mär, Germany, the capital of the state of Thuringia on the Ilm River, 13 miles east of Erfurt. It stands in a beautiful valley surrounded by hills, on ground partly elevated and partly flat. It is irregularly built except in the suburban portions. Its notable public edifices are the grand-ducal palace, a handsome structure erected partly under the superintendence of Goethe; the so-called Red and Yellow castles, now united and occupied by several public departments; the grand-ducal library (in the Green Castle), containing 300,000 volumes and a large collection of maps; the museum; the Stadtkirche, with an altar-piece, one of the finest works of Lucas Cranach, in which he has introduced portraits of himself and Luther and Melanchthon; and the modern Gothic townhouse. The public monuments comprise the Goethe-Schiller monument in bronze, statues of Herder, Wieland, the composer Hummel, the Grand-Duke Karl August and various others, and a monumental fountain. Goethe's house is now used as a Goethe National Museum, and Schiller's contains relics of its former distinguished owner. A Goethe and Schiller Archives building was opened in 1896. Goethe and Schiller are interred in the grand-ducal vault in the new cemetery. Stretching away from the palace is a fine park on the banks of the Ilm. Weimar has a gymnasium, a realgymnasium, academy of painting, school of drawing, normal school and other educational institutions. It has neither trade nor manufactures of much consequence, the manufactures of iron, wood, straw, leather and cloth being carried on to some extent, but as the capital of the state it is the seat of the legislature and of all the more important courts and public offices. It long ranked as a sort of "German Athens" in consequence of the enlightened patronage which the Duke Karl August (d. 1828) afforded to the four great literary men of Germany, Goethe, Schiller, Herder and Wieland. In 1919 the National Assembly of the German nation met at Weimar and there the constitution of the new German Republic was made and adopted. The Treaty of Versailles (1919) was ratified at Weimar during the session of the assembly. Population (1939) 65,989.

WEINBERGER, vīn'bĕrg-ûr, **Jaromir,** Czechoslovak composer: b. Prague, Jan. 8, 1896. Pupil of Karel Hoffmeister, Jaroslav Křička and Max Reger. Teacher of composition in the Ithaca Conservatory, Ithaca, New York 1922–1926; later teacher and conductor in Bratislava, Moscow, Vienna, and London; since 1939 resident in Fleishman, New York. Influenced in his earlier works by French impressionism, Weinberger later applied his skillful orchestration to the eclectic organization of folklore material. His compositions include: *Czech Rhapsody; Lincoln Symphony;* a sonata, and other piano and orchestral works; a ballet, *The Seduction of Evelina* (1917); the operas *Švánda Dudak* (*Schwanda the Bagpiper,* 1927; New York 1931), his most successful work; *Die Geliebte Stimme* (1930); *The Outcasts of Poker Flat* (1932); *Wallenstein* (1937); and an operetta, *Frühlingstürme* (1932).

WEINGARTNER, vīn'gärt-nĕr, **Felix von,** Austrian conductor and composer: b. Zara, Dalmatia, June 2, 1863; d. Winterthur, Switzerland, May 7, 1942. He studied at Graz under W. A. Remy; at Leipzig Conservatory; and under Liszt at Weimar, where his first opera, *Sakuntala,* was produced in 1884. He subsequently held important posts as kapellmeister, leading the royal orchestra in Berlin from 1891 to 1898; served as conductor or director in Munich, Vienna, and Basle, and from 1935 again at Vienna; and conducted concerts in New York (1905), Boston (1912–1913), and in London and South America (1919). Among his important compositions are the operas *Malawika* (1886); *Genesius* (1892); and *Orestes* (1902); six symphonies; two symphonic poems; a violin concerto, much chamber music, and many songs. He also edited works of Berlioz, Weber, and Méhul, orchestrated a Beethoven sonata, and wrote several books on musical subjects, including a volume on conducting.

WEINMAN, Adolph Alexander, American sculptor; b. Karlsruhe, Germany, Dec. 11, 1870. He came to the United States when a child and later studied art in New York, under Saint Gaudens at the Art Student's League, and at Cooper Union. He is a member of the National Academy, the National Sculpture Society and the National Institute of Arts and Letters. In 1915 he served on the International Jury of Awards at the Panama Exposition. Among his works are the General Macomb Monument at Detroit, Mich.; the Lincoln memorials, Hodgenville, Ky., and Madison, Wis.; the Lincoln statue, State Capital, Frankfort, Ky.; the statuette of Lincoln, Metropolitan Museum, New York; sculptures for the post office, Supreme Court and Archives buildings, Washington, 1933.

WEIR, wēr, **Harrison William,** English artist and journalist: b. Lewes, Sussex, May 5,

1824; d. Appledore, Kent, Jan. 3, 1906. He was apprenticed to the color printer George Baxter (1804–1867) and was later employed as an illustrator for the *Illustrated London News* and for other periodicals, such as the *Graphic,* the *Pictorial Times,* and the *Black and White.* A great lover of animals and an expert poultry breeder and horticulturist, Weir illustrated—and occasionally wrote—many books on natural history, domestic animals, and animal stories.

WEIR, John Ferguson, American artist and writer: b. West Point, N. Y., Aug. 28, 1841; d. Providence, R. I., April 8, 1926. He was a pupil of his father, Robert Walter Weir. He became a member of the National Academy of Design in 1866; director of Yale University School of Fine Arts in 1869; and retired in 1913. He is known by his statues of President Woolsey and Professor Sullivan of Yale; and by his paintings, which are grouped with the Hudson River School. Deeply interested in religion, he wrote *Human Destiny in the Light of Revelation* (1903).

WEIR, Julian Alden, American artist: b. West Point, N. Y., Aug. 30, 1852; d. New York, N. Y., Dec. 8, 1919. The son of Robert Walter Weir, he studied with his father and at Paris with Jean Léon Gérôme. Weir's painting was strongly influenced by the French impressionists, but is even closer to the work of James Whistler, showing clearly the influence of the decorative aspects of Japanese art. Examples are to be found in the Luxembourg, Paris, and in a great many art museums in the United States. *Breton Interior* obtained a second-class medal at the Paris Exposition of 1889. His *Idle Hours,* now in the New York Metropolitan Museum, received the $2,000 prize of the American Art Association. In the same gallery are *The Red Bridge* and *The Green Bodice,* the latter one of Weir's masterpieces. Weir's long career as an artist was marked by independence and naturalness. It was only after repeated experiments that he achieved the general recognition which the reticent, refined, and distinguished style of his maturity deserved.

WEIR, Robert Stanley, Canadian lawyer and poet: b. Hamilton, Ontario, Nov. 15, 1856; d. near Lake Memphremogog, Quebec, Aug. 20, 1926. He was educated at McGill University and in 1881 was called to the Quebec bar. He then practiced in Montreal, and in 1926 was named a judge of the Exchequer Court of Canada.

Weir was the author of a number of legal treatises, and two volumes of verse, *After Ypres and Other Verses* (1917) and *Poems, Early and Late* (1923).

His best-known lyrics are the words to the Canadian song, *O Canada!*

WEIR, Robert Walter, American artist: b. New Rochelle, N. Y., June 18, 1803; d. New York, N. Y., May 1, 1889. After studying under John Wesley Jarvis he began portrait painting in 1821 and in 1824 went to Italy, where he studied in Florence under Pietro Benvenuti, and in Rome. In 1829 he became a national academician and was professor of drawing at the military academy at West Point, 1837–1879. He was of especial prominence as a historical painter. Among his works are the *Embarkation of the Pilgrims* (1836–1840) in the rotunda of the Capitol at Washington; and *Peace* and *War,* painted for the chapel at West Point. John Ferguson Weir and Julian Alden Weir were his sons.

WEIRTON, wēr't'n, city, West Virginia; in Hancock and Brooke counties. It is situated on the Ohio River, 33 miles west of Pittsburgh, Pa., and is served by the Pennsylvania Railroad. Weirton is a steel-manufacturing center, with one of the largest tin-plating plants in the world. There are also manufactures of chemicals and cement products. In the late 1790's a blast furnace was built here by Peter Tarr, who in 1813 supplied cannon balls for Oliver Perry's fleet on Lake Erie. Tarr's furnace is preserved by a local commission. Although it grew rapidly after 1910, Weirton and its neighboring communities remained unincorporated until 1947, when Weirton, Weirton Heights, Marland Heights, and Hollidays Cove were consolidated. Government is by mayor, city manager, and council. Pop. (1950) 24,005.

WEISER, wē'sēr, city, Idaho; seat of Washington County; altitude 2,115 feet. It is situated on the Snake River, 62 miles northwest of Boise, and is served by the Union Pacific Railroad. The surrounding area is interested in stock raising and mining. It has a flour mill, dairy products plant, iron foundry, brick and bottling works, and ships fruits. There are large deposits of gold, silver, copper, iron, gypsum, and other ores in the nearby Seven Devils Mountains. The city was laid out in 1877 and incorporated in 1887. The original settlement, however, was destroyed by fire in 1890. Pop. (1950) 3,961.

WEISHAUPT, vīs'houpt, **Adam,** German mystic: b. Ingolstadt, Feb. 6, 1748; d. Gotha, Nov. 18, 1830. Educated at Ingolstadt, he there became in 1772 extraordinary professor of law and in 1775 professor of natural and canon law. His appointment to the latter post brought him into collision with the clergy, especially the Jesuits, whose bitter enemy he became. At Ingolstadt in 1776 he founded the secret, rationalistic anticlerical order of the Illuminati (q.v.), whose doctrines are said to have been systematized by Baron Adolphus Knigge (q.v.) and other Freemasons. In 1784, however, Knigge withdrew after a quarrel, and in 1785 Weishaupt was obliged to leave Ingolstadt and in 1787 settled in Gotha, where he was later made a councillor of state by the duke. He is said to have severed all connection with the Illuminati after 1787 and to have died reconciled with the Catholic Church.

Weishaupt's most important writings are *Geschichte der Verfolgung der Illuminaten in Baiern* (1786), and *Das verbesserte System der Illuminaten* (1787).

WEISMANN, vīs'män, **August,** German biologist: b. Frankfurt am Main, Jan. 17, 1834; d. Freiburg im Breisgau, Nov. 5, 1914. He studied medicine at Göttingen, and after devoting himself especially to the natural sciences in 1863 went to Giessen to study zoology under Rudolf Leuckart. He was appointed extraordinary professor at the University of Freiburg in 1866; ordinary professor there in 1873. In 1875–1876 he published *Studien zur Deszendenztheorie,* which was translated into English in 1882 as *Studies in the Theory of Descent,* with a preface by Charles Darwin. A series of treatises in which he developed his characteristic theories (for which see WEISMANNISM), included *Über die Vererbung* (*On Heredity;* 1883).

'Uber die Dauer des Lebens' ('On the Duration of Life'), 'Ueber Leben und Tod' ('On Life and Death'), 'Die Kontinuität des Keimplasmas als Grundlage einer Theorie der Verebung' ('The Continuity of the Germ-Plasm as the Basis of a Theory of Heredity'), 'Die Bedeutung der Sexuellen Fortpflanzung für die Selektionstheorie' ('The Significance of Sexual Reproduction for the Theory of Selection'), 'Ueber den Rückschritt in der Natur' ('On Retrograde Development in Nature') and 'Amphimixis.' These have appeared in an English translation under the title 'Essays upon Heredity and Kindred Biological Problems' (Vol. I, 1889; Vol. II, 1892). Weismann's other works include 'Das Keimplasma' (1892), in English as 'Germ Plasm' (1893); 'Die Allmacht der Naturzüchtung' ('The Omnipotence of Natural Selection,' 1893); 'Aeussere Einflüsse als Entwickelungsreize' ('External Influences as Stimuli to Development,' 1894); 'Neue Gedanken zur Vererbungsfrage' ('Fresh Thoughts on the Question of Heredity,' 1895); and 'Ueber Germinalselektion' ('On Germinal Selection,' 1896). See HEREDITY; WEISMANNISM.

WEISMANNISM, the essential teaching of August Weismann (q.v.), sometimes referred to as "Neo-Darwinism." Interest and controversy have gathered mainly round his answer to the question, "How is it that a single cell of the body can contain within itself all the hereditary tendencies of the whole organism?" In all theories of heredity (q.v.) biologists have assumed that characters acquired by the individual are transmitted to offspring. This Weismann denies and while biologists have concerned themselves with speculation as to the mode by which such transmissions are effected, he challenges them to prove that they are effected at all. The burden of proof is thus thrown upon his opponents, whose assumptions must give way to experimental evidence, which alone can determine, and that only after protracted record of cases, whether individually acquired characters are transmitted or not. Death, he contends, is not a primary attribute of living matter; the protozoans, or one-celled organisms, being immortal in so far that they do not die naturally. The protozoan, a microscopic jelly-like, apparently — not really — structureless mass, with no seeming unlikeness of parts, multiplies by division. Each half becomes a complete individual and grows in like manner as the whole to which it belonged, till it also divides and so on with the multiplication of protozoans *ad infinitum.* It cannot be said of either half that one is parent and the other offspring, for both are of the same age, and only, in a limited sense, as the subdivisions into separate individuals are repeated, can we speak of succession of generations. In these processes there is nothing analogous to death. "There are," Weismann says, "no grounds for the assumption that the two halves of an amœba are differently constituted internally, so that, after a time, one of them will die while the other continues to live. Observations show that when division is almost complete the protoplasm of both parts begins to circulate and for some time passes backward and forward between the two halves. A complete mingling of the whole substance of the animal and a resulting identity in the constitution of each half is thus brought about before the final separation? Consequently, there is unlimited persistence of the individual; potential, although not absolute, immortality so long as life lasts on the earth.

While the one-celled organisms are thus immortal, only the reproductive cells of the metazoans, the many-celled, are immortal. How has this come about? Weismann accounts for it by the failure of certain protozoans to divide equally, whereby unlikeness of parts and differences of position of parts resulted. "The first multicellular organisms were probably clusters of similar cells, but these units soon lost the original homogeneity. As the result of mere relative position there arose division of labor. some of the cells were especially fitted to provide for the nutrition of the colony, while others undertook the work of reproduction." Clearly, those on the outside, being exposed to the direct and constant action of their surroundings, would be the media of nutrition, and the builders-up of the cell-commonwealth. So the result of this cell-clustering would be that the cells fell into two classes, body cells and germ-cells. While the body cells were solely concerned with the nutrition of the organism, losing in this specialization of function the power of reproduction, that power became concentrated in the germ-cells, or, speaking more precisely, in the germ-plasm, which is located in the nucleus of the germ-cell. It is these germ-cells which are the immortal part of the metazoans. With increasing subdivision of function there has been increasing modification of the organism, but the two-fold classification of the somatic or body cells and the germ-cells has remained. The death of the body cells is involved in the ultimate failure to repair waste, because a worn-out tissue cannot forever renew itself, and because cell-division has its limits. In brief, death is the penalty paid for complexity of structure. As it is impossible for the germ-cell to be, as it were, an extract of the whole body, and for all the cells of the body to dispatch particles to the germ-cells whence these derive their power of heredity (the fundamental idea of Darwin's theory of pangenesis, q.v.), the germ-cells, so far as their essential and characteristic substance is concerned, are not derived from the body of the individual, but directly from the parent germ-cell. Heredity, Weismann contends, is secured by the transference from one generation to another of a substance with a definite chemical and molecular constitution — in other words, by the "continuity of the germ-plasm." This germ-plasm (which, Weismann's critics argue, runs perilously near a metaphysical concept) is assumed to possess a highly complex but extremely stable structure, so stable "that it absorbs nourishment and grows enormously without the least change in its complex molecular structure." Of this germ-plasm it is further assumed that a small portion contained in the parent egg-cell is not used up in the construction of the body of the offspring, but is reserved unchanged for the formation of the germ-cells of the following generations. Only variations of the germ-plasm itself are inherited, and it is upon these variations that natural selection operates. Variations are due not to

the influence of external condition nor to use or disuse of organs, but to sexual conjugation. The process combines two groups of hereditary tendencies derived from the mingled germ-plasms of the male and female parents, resulting in those individual differences which form the material from which new species are produced by the action of natural selection. Those differences multiply in geometrical ratio.

The sum of the matter is that natural selection (q.v.) is the dominant factor, that use and disuse of parts and the action of the environment count for nothing, or, at the most, for but a little. (See USE AND DISUSE). Here and there Weismann makes concessions as to the modifying influences of body cells on the germ-cells, and as to the ultimate origin of hereditary individual differences in the direct action of surroundings, which are a partial surrender of his main contention as to the isolation of the germ-plasm. It is not easy to reconcile the theory of an insulated germ-plasm with the ceaseless manufacture, secretion and expulsion of germ-cells, the materials of which are derived from the materials nourishing the entire organism; nor with the subtle influence of the nervous system on the reproductive organs.

Perhaps the most serious difficulty in Weismann's theory is in the reconciliation of psychological evolution with the continuity of the germ-plasm. For the researches of Spencer, Balfour and others have demonstrated that the nervous system had its origin in modifications of the primitive skin due to the direct action of the environment. Though we criticise his theory in our present knowledge, we do grant that to him science owes a great debt. The conception of the isolation of the germ cells from somatic influences we owe to him and the belief that the chromosomes represent the parts of the nucleus which have special significance in the process of heredity.

Bibliography.—Haeckel, 'Generelle Morphologie' (1866); Darwin, 'Variation Under Domestication' (1868); Brooks, 'The Law of Heredity' (1883); Virchow, 'Descendenz und Pathologie' (Virchow's Archiv, ciii, 1886); Eimer, 'Die Entstehung der Arten' (1888); Galton, 'Natural Inheritance' (1889); Romanes, 'An Examination of Weismannism' (1893); Spencer, 'A Rejoinder to Professor Weismann' (1894); Hertwig, 'The Biological Problem of To-day' (1894). For critiques of Weismann, consult Eimer, Virchow, *op. cit.*; Spencer, 'Factors of Organic Evolution' (1886); Lock, R. H., 'Variations, Heredity and Evolution' (1916).

WEISS, Charles Andre, French authority on international law: b. Mulhouse, Alsace, 30 Sept. 1858. He took his LL.D. at the University of Paris in 1880 and later became a member of the faculty there. He has been prominently connected with various societies and commissions dealing with international law, and has written voluminously and with praiseworthy clarity upon the subject. He is a chevalier of the Legion of Honor. He has been President of the Institute of International Law since 1921 and is professor of international law at the University of Paris. Author of 'Le droit civil et la legislation comparée' (1900); 'The Violation by Germany of the Neutrality of Belgium and Luxemburg' (1915); 'La Reparation des dommages de guerre' (1917); 'Manuel de droit international privé' (1882, 8th ed. 1921).

WEISS, John, American clergyman: b. Boston, 28 June 1818; d. there, 9 March 1879. He was graduated at Harvard in 1837; in the winter of 1842–43 studied at Heidelberg, Germany; was graduated in the last-named year at the Harvard Divinity School, and settled as minister of a Unitarian church in Watertown, Mass. His anti-slavery utterances having disturbed the harmony of his pastorate, he resigned, and in 1847 became minister of a Unitarian society in New Bedford, Mass., but was soon compelled by reason of ill health to retire. Again in 1859–70 he was minister of the Watertown church, from which he finally withdrew in order to pursue his literary work. He was one of the most brilliant of the New England reformers and transcendentalists, and his writings display a mind at once mystical and scientific, strongly rationalistic on religious subjects, but endowed with a fine poetic power of interpretation, which he applied to religious history and symbolism, as well as to questions of philosophy and life, to which he brought prophetic insight and fervor. His publications include 'Æsthetic Prose' (1845), a translation of Schiller's philosophical and æsthetic essays; 'Life and Correspondence of Theodore Parker' (1864); 'American Religion' (1871); 'Wit, Humor, and Shakespeare' (1880); and 'The Immortal Life' (1880).

WEISSENFELS, vīs'sĕn-fĕls, Germany, town in the Prussian province of Saxony, on the Saale River, 14 miles southwest of Leipzig, on the main line of the railroad from Bebra to Frankfort-on-the-Main. It was the capital of the duchy of Saxe-Weissenfels in 1656–1746. The Augustusburg Palace, built in 1664–90, is now used as a military school. There are deposits of lignite and sandstone in the vicinity. Manufactures include machinery, ironware, shoes, paper, sugar and electrical appliances. Pop. about 35,000.

WEITENKAMPF, Frank, American connoisseur of prints: b. New York, 13 April 1866. He studied at the Art Students' League, New York. He is chief of the art and print departments of the New York Public Library, where he has done notable work in arranging continuous exhibitions of carefully selected prints. In 1914 New York University gave him the degree L.H.D. He has prepared many pamphlets cataloging and describing prints; has contributed to various encyclopedias and to the 'Standard Dictionary'. Author of 'How to Appreciate Prints' (1908; new ed. 1932); 'American Graphic Art' (1912; new ed. 1924); 'The Etching of Contemporary Life' (1916). He edited 'Famous Prints: Masterpieces of graphic art reproduced with critical notes' (1926).

WEITLING, Wilhelm Christian, German communist: b. Magdeburg, Prussia, 1808; d. New York, 25 Jan. 1871. He early became an advocate of communism, traveling and lecturing in its behalf. He took part in the Revolution of 1848 and afterward came to the United States. He founded the Socialist society known as Arbeiterbund in New York, and was connected with the establishment of a communistic colony in Wisconsin, although he lived in New York. Author of 'Guaranties of Harmony and

Freedom (1842); *Humanity as It Is and as It Should Be* (1845).

WEITSPEKAN INDIANS, wīt'spĕk-ăn (from *Weitspek,* the name of one of their towns). A linguistic stock of North American Indians, comprising several small tribes collectively known as the Yurok, occupying the lower Klamath River in California, from the mouth of the Trinity down. On the coast, Weitspekan territory extends from Gold Bluff to about six miles above the mouth of the Klamath. The Chilula are an offshoot of the Weitspek, living to the south of them, on Redwood Creek to a point about 20 miles inland, and from Gold Bluff to about midway between Little and Mad rivers.

WEIZMANN, vīts'män, **Chaim,** Israeli statesman and scientist: b. Motele, near Pinsk, Russia, Nov. 27, 1874; d. Tel Aviv, Israel, Nov. 9, 1952. He studied at the universities of Berlin and Freiburg, and in 1901 was appointed lecturer in chemistry at Geneva. In 1904 he went to England, becoming reader in biochemistry at the University of Manchester and in 1910 securing naturalization as a British subject. Soon after appointment in 1916 (during World War I) as director of the laboratories of the British Admiralty, he discovered a process of synthesizing acetone, employed in the manufacture of high explosives; he retained this post until 1919. He had been an ardent Zionist for many years, and in 1917 he was largely instrumental in securing the British government's undertaking (the Balfour Declaration) that a national home for the Jews would be established in Palestine. He served as president of the World Zionist Organization from 1921 to 1929, and of the Jewish Agency for Palestine during the next two years; in 1931 he was also elected president of the Zionist Federation of Great Britain and Ireland. From 1935 to 1946 he was again president of the Jewish Agency, in this capacity taking a prominent part in the events which led up to establishment of the state of Israel. He was president of the board of governors of the Hebrew University in Jerusalem from 1932 onwards, and he was also director of the Daniel Sieff Institute, at Rehovoth, where much of his time was spent. His scientific work there was largely in the field of agronomics, notably research and experimentation on the castor bean. On May 16, 1948, following proclamation of the new state of Israel, he was elected by the State Council president of the council of government, a post tantamount to provisional president of the state.

WELCH, Ashbel, American civil engineer: b. Nelson, N. Y., Dec. 4, 1809; d. Lambertville, N. J., Sept. 25, 1882. From 1835 to 1874 he was chief engineer of the Delaware and Raritan Canal. He also constructed the Belvidere and Delaware Railroad, and in 1862 was appointed manager of the New Jersey lines of the Pennsylvania Railroad. The block system (q.v.) in railroading was introduced into the United States by him.

WELCH, Herbert, American bishop and educator: b. New York City, Nov. 7, 1862. He graduated at Wesleyan University in 1887 and at Drew Theological Seminary three years later, and was ordained in the ministry of the Methodist Episcopal Church. In 1905, after occupying several pastorates in the New York City area, he was elected president of Ohio Wesleyan University. He served in that post until 1916, when he became resident bishop of his church in Japan and Korea. Returning from the Orient in 1928, he spent four years as bishop of the Pittsburgh, Pa., area, and in 1932 he went to China as bishop of the Shanghai area; there he remained until his retirement in 1936. From 1938 to 1939 he was resident bishop of the Boston, Mass., area; and from 1940 to 1948 he was chairman of the Methodist Commission for Overseas Relief. His books include *That One Face* (1925); and *Men of the Outposts* (1937).

WELCH, Philip Henry, American humorist: b. Angelica, N. Y., March 1, 1849; d. Brooklyn, N. Y., Feb. 24, 1889. He was a journalist on the Rochester, N. Y., *Post-Express* from 1882 to 1884, and thereafter he was a member of the staff of the New York *Sun.* A popular humorist and satirist, he published a selection of his columns under the title *Said in Fun* (1889).

WELCH, William Henry, American pathologist: b. Norfolk, Conn., April 8, 1850; d. Baltimore, Md., April 30, 1934. After securing his medical degree at Columbia University in 1875 he continued his studies in Germany, and in 1878 he established at Bellevue Hospital Medical College, New York City, the first pathology laboratory in the United States. He went to Johns Hopkins University in 1884 as Baxley professor of pathology; he held this post until 1916, and from 1889 he was also pathologist to Johns Hopkins Hospital. From 1916 to 1926 he was director of the newly established Johns Hopkins School of Hygiene and Public Health, then becoming professor of the history of medicine, a chair he continued to occupy until his retirement in 1930. He was chairman of the board of scientific directors of the Rockefeller Institute of Medical Research from 1901 until his death. The bacteria causing gas gangrene, which he studied, was named for him Welch bacillus.

WELCH, town, West Virginia, McDowell County seat, on the Big Sandy River 36 miles west of Bluefield; it is served by the Norfolk and Western Railroad. The town was named for Isaiah Welch, a Confederate officer who developed coal lands in the vicinity. Pop. (1940) 6,264; (1950) 6,603.

WELCKER, vĕl'kĕr, **Friedrich Gottlieb,** German classical philologist and archaeologist: b. Grünberg, Hesse, Nov. 4, 1784; d. Bonn, Prussia, Dec. 17, 1868. He was educated at the University of Giessen, where he became professor of archaeology in 1809; successively, he occupied like chairs at the universities of Göttingen, 1816–1819, and Bonn, 1819–1861.

WELD, Theodore Dwight, American abolitionist: b. Hampton, Conn., Nov. 23, 1803; d. Hyde Park, Mass., Feb. 3, 1895. Impaired sight necessitated his leaving Phillips Andover Academy. He was one of the 63 original founders of the American Anti-Slavery Society, and from 1830 to 1833 he was general agent of the Society for the Promotion of Manual Labor in Literary Institutions. In 1833 he entered Lane Theological Seminary, Cincinnati, Ohio; in the evenings he taught colored youths. He was charitable and disinterested, and did not

hesitate to denounce slavery and the slave trade openly and publicly. He left the seminary when the trustees suppressed the local antislavery organization and began a course of lectures. He was repeatedly mobbed, but his commanding presence and athletic attainments, as well as his fearless and wonderful eloquence, enforced respect; at Granville, Ohio, when advised that the church would be burned if he lectured as advertised, he informed the trustees that he would then speak from its foundations; to threatening letters he replied: "Come, but bring your own winding sheets, which I cannot supply"; six undisturbed lectures followed. At Painesville, Ohio, such was his eloquence that the leader of the mob kicked in the head of the bass drum with which he had thought to drown the speaker's voice. In 1836 his voice partially failed him, but he taught school and used his pen vigorously. In 1838 he married Angelina Emiline, daughter of Judge John Grimke, of South Carolina, who, having become a Quaker in 1835, emancipated her inherited slaves. He edited the American Anti-Slavery Society's publications in Washington, D.C., and was confidential adviser with congressmen who favored abolition of slavery in the District of Columbia.

WELDING. Introduction.—Although welding in its elementary form has been known for hundreds of years, it was during World War I that its application became important from an industrial standpoint. Basically, welding is the joining of two or more metal parts into a homogeneous unit by means of heat and pressure.

A *weld* according to the standard definition of the American Welding Society is "A localized coalescence of metal wherein coalescence is produced by heating to suitable temperatures, with or without the application of pressure, and with or without the use of filler metal. The filler metal either has a melting point approximately the same as the base metals or has a melting point below that of the base metals but above 800°F."

Welding is defined as "The metal joining process used in making the weld." The American Welding Society in its Master Chart of Welding Processes lists thirty-seven such processes. (See Fig. 1.) Each of these processes accomplishes the same basic purpose, that is, providing the heat and pressure necessary to obtain a weld.

As a general rule the welding processes are complementary rather than interchangeable; which process to use is determined by the specific application, by the material involved, by the production facilities available and other similar factors.

The Master Chart of Welding Processes divides the welding processes into eight separate groups, in all but one case the division being on the basis of the source of heat, i.e., arc, gas, forge, etc. The group which is the exception, brazing, differs from all the other groups in that capillary attraction is necessary to secure the proper flow of the brazing alloy or filler metal.

The most commonly used groups of processes, gas welding, arc welding, resistance welding and brazing are discussed in detail in separate articles. The other groups of processes are discussed together in the article at the end of the series.

In industry it is common to develop variations in one or another of the welding processes to satisfy specific production requirements. These variations, according to the standard nomenclature of the American Welding Society are known as *methods*. For example, oxyacetylene welding of steel castings using a bronze welding rod is known as *braze welding*. Similarly in resistance welding, push welding (or poke welding), which is the making of a spot weld using one electrode and a backing bar, is a method of spot welding.

The third principal distinction between one welding application and another is the *procedure*, which is the detailed methods and practices involved in making a weldment. A welding procedure would include such factors as current, voltage, position of welding for arc welding; torch tip size, size of welding rod and position of welding for gas welding; current, voltage, electrode size and shape for resistance welding and similar factors for other welding processes. In addition a welding procedure for any of the processes would include the order in which successive welds are to be made to complete the structure and any heat-treatment which may be necessary.

Industrially, welding is used today in every major industry. In tooling-up for a new model, an automobile manufacturer may spend upward of a million dollars on resistance welding equipment; other welding equipment does not require such major expenditures. Many, many bridges and buildings are fabricated by welding, and where noise abatement is necessary during construction, as is the case in building hospital additions, the use of welding is usually mandatory. Large boilers, pressure vessels for chemicals and petroleum products and gravity storage tanks are almost always welded today. Without welding, the shipbuilding and aircraft industries would never have been able to meet the enormous demands for planes and ships to fight World War II. Large pipelines, such as the "Big Inch" and the "Little Inch" are joined by welding. For the home, brazing and other welding processes are commonly used in manufacture of refrigerators, radios, cabinets and similar metal products. The handles of pots and pans are economically and permanently attached to the pots and pans themselves by spot or projection welding. Street railway tracks as well as railroad tracks are joined to make continuous lengths by thermit welding. Bicycle frames are usually brazed.

The materials used in these structures and products include practically every metal and alloy commonly used: low-carbon and high-carbon steels as well as a variety of alloy steels including stainless steels; aluminum, magnesium; copper, brass, bronze, lead; cast iron, wrought iron; nickel, Monel; Inconel; silver; gold; and platinum.

SIMON A. GREENBERG,
Technical Secretary, American Welding Society.

ARC WELDING

The remarkable growth of the process of arc welding has made this modern method of construction and maintenance an outstanding development in industry. Although welding had come into its own long before the outbreak of World War II the simplicity and high speed in metal fabrication made possible by the electric arc were dominant factors in shortening the war in Europe and assuring a successful conclusion to the conflict in the Pacific. Not only did welding permit the mass construction of ships, airplanes, guns, tanks, and other essential military equipment in record-breaking time, but the economy

effected through its general use was responsible for surprising decreases in the cost of producing such materiel.

Although arc welding has been known since 1881, when arc lights were first introduced, the process did not come into general use until about the time of World War I, when improved methods facilitated its use. Following the principles of the carbon arc light, a Russian, N. V. Bernardos, developed a carbon arc welding process which was patented in 1887. A few years later, another Russian, Nicholas Slavianoff, developed an arc welding process similar to the carbon arc process except that, in the latter case, the arc was formed between a metallic wire, or electrode, and the work to be welded. This process is known as metallic arc welding, patents on which were issued in the United States to C. L. Coffin in 1889.

An arc lamp has two carbon electrodes, the ends of which are slightly separated. When a powerful electric current passes from one electrode to the other, it has to jump the gap between them. In doing so, the electricity generates intense heat between the tips of the electrodes. This intense heat produces the brilliant light, or arc, from which the arc lamp takes its name.

The arc for welding is produced in a similar way, except that one end of the circuit becomes the work to be welded. An electric current is forced to jump the gap between the electrode and the work being welded to complete its circuit. Current is carried from the arc-welding machine, through an insulated wire cable, to the electrode, and then across the gap, to produce the heat necessary for welding. It then goes back to the welding machine through another cable, thus forming a complete electrical circuit. As the electric current jumps the gap, it generates an intense heat that immediately melts the metal to be welded. The temperature of the electric welding arc is probably in excess of 3,583°C. (6,500°F.).

While the arc for an arc lamp and the arc for welding are the same in principle, there is one very important difference. In one instance, the arc heat is used to produce *light;* in the other, it is used to produce heat, to melt steel, or some other metal.

The heat of the welding arc, produced by the electrical current in crossing the gap, melts the part, or parts, being welded, and also melts the end of the electrode. The molten metal from the tip of the electrode flows across the arc to the part being welded. In some metal arc processes the electrode does not melt but an additional filler rod is used. When the melted steel cools, the parts which have been welded together—no matter how many there are in the particular structure—have become a single piece. Not only is the welded structure one integral unit but, when mild steel is used, the structure may be actually stronger in the welds than anywhere else.

The remarkable simplicity of arc welding lies in its ability to join metal directly, in many cases, without intermediate connecting members, and without the many operations of other industrial processes. This simplicity of operation has improved the quality, and reduced the cost, of many products, and of every type of structure.

The benefits made possible by welding, as compared to other methods used in construction have affected such a wide range of items that any attempt to enumerate them would mean listing practically every kind of structure and product made of metal, from huge battleships and buildings to small parts of delicate machinery. In addition to making the fabrication of metal structures faster, easier, and more economical, arc welding has become more and more versatile in serving its original purposes as a tool for repairing broken parts, and for resurfacing (building-up) worn surfaces.

The process first received general recognition during World War I when the dynamited cylinders of some interned German vessels were successfully repaired by metal arc welding. Doubtless one of the reasons for its present widespread acceptance is the fact that the selling price of welding equipment and supplies was continuously reduced during its development.

Molten steel has an affinity for oxygen and nitrogen. Exposed to air, molten steel enters into chemical combination with oxygen and nitrogen to form oxides and nitrides. These impurities tend to weaken and embrittle the steel, as well as affect some of its other properties such as lessen its resistance to corrosion.

In an unshielded arc, molten globules which pass from electrode to work are exposed to an ambient atmosphere which contains oxygen and nitrogen. Molten base metal is also exposed to these elements. If the metal, during solidification, is completely protected from contact with ambient atmosphere, no injurious chemical combination can take place. Such protection can be achieved by completely shielding the arc. Tremendous impetus was given welding by the commercial development of the shielded type of electrode in 1929. This important technical advance constituted a vast improvement over the commonly used bare electrode, and also over certain lightly-coated electrodes. The latter had been used in some degree, but were found commercially impractical because of their high cost and slow speed.

The Shielded Arc.—An arc can be shielded by completely enveloping it with an inert gas, which will not enter into chemical combination with molten metal and at the same time will prevent contact with atmospheric oxygen and nitrogen. Welds made with a completely shielded arc are largely free of oxides and nitrides, and are therefore composed of metal having superior mechanical characteristics to that of metal deposited by an unshielded arc.

In manual welding a shielded arc is obtained through the use of specific types of electrodes which are heavily coated. The heavy coating is of such composition that, in the heat of the arc, it gives off a gas which envelopes and shields the arc from the ambient atmosphere.

The action of the arc on the coating of the electrode results in a slag formation, which floats on top of the molten weld metal and protects it from the ambient atmosphere while cooling. After the weld metal is sufficiently cooled, the slag may be easily removed.

Metallic Arc Welding.—In metal arc welding, regardless of whether shielded or bare electrodes are employed, the arc occurs between the work to be welded and a metal wire. Under the intense heat developed by the arc, a small part of the work to be welded is brought to the melting point almost instantaneously. The other end of the arc, the tip of the electrode, is likewise melted, and tiny globules of molten metal form. Those globules are then forced across the arc and deposited in the molten seat waiting for it in

the work. The globules are actually forced across the arc, as gravity does nothing more than assist this deposition of metal when the work is flat. It is this fact which permits the use of metal arc welding in an overhead position.

Carbon Arc Welding.—In carbon arc welding, the arc is formed between the work and a carbon rod held in the electrode holder. The heat of the arc melts a small pool in the surface of the work to be welded. This pool is kept molten by playing the arc across it, and extra metal to form the weld is added by a filler rod. Carbon arc welding is a puddling process, and is not applicable to vertical or overhead welding. Its greatest use is in automatic welding, or in specialized applications.

Automatic Welding.—In automatic welding, a completely shielded arc can be obtained by employing either the carbon arc or the metal arc. In the automatic carbon arc process, a specially prepared substance is introduced into the arc flame at the point of fusion. The combustion of this substance in the arc provides an inert gas which completely encloses and shields the arc from the ambient atmosphere. Another form of shielding is obtained by the automatic deposition of powder on the joint ahead of the arc. The arc penetrates through the powder to weld the joint. In addition to the inert gas formed, a slag is produced which floats on top of the molten metal and protects it from the atmosphere while cooling. In the automatic metal arc method known as submerged arc welding, welds are made under a heavy granular flux, automatically fed onto the seam just ahead of the arc. In this process the flux completely covers the arc, acting as a refining agent for the molten weld metal and also protecting the hot solid bead from the ambient atmosphere during cooling. In submerged arc welding, the welding bead, flux hopper, and spool of welding wire may be mounted on a portable tractor unit, or, in certain kinds of work, it may be mounted to travel on an overhead beam. In another arrangement, the unit is mounted on a special adjustable fixture designed to accommodate specific types of work. These simple yet effective methods of shielding the arc permit a very economical production of welds which possess physical properties equal to, or better than, those of mild rolled steel.

New Types of Arc Welding.—In addition to automatic and manual, metal and carbon arc welding, several other arc welding processes have been developed for welding specialized types of work.

Atomic-hydrogen arc welding is used for welding both ferrous and nonferrous metals, but it is especially useful in welding thin sheet metal where a high finish is required. In this process an arc is established and maintained between two tungsten electrodes while a stream of hydrogen gas is passed through the arc. As this hydrogen reverts to molecular form in the arc, an intense heat is given which is used to fuse the metal being welded. The work does not form part of the welding circuit so the arc must be played over the surface of the metal in much the same manner as is a gas torch. The process has certain advantages but is generally more expensive than the metal arc process.

Inert-gas arc welding is employed for welding nonferrous metals such as aluminum and magnesium. This process uses a single tungsten electrode and the arc is made between the electrode and the work. The electrode is not consumed during welding. A filler rod is used when extra metal is needed for the joint. The arc, filler metal and pool are shielded by a mass of inert gas (helium or argon) which is supplied through an opening in the insulated tube surrounding the electrode. The process is used both manually and automatically.

Source of Current Supply for Arc Welding.—Arc welding requires a continuous supply of electrical current, sufficient in amount, and of proper voltage. Voltage across the arc will range from about 15 volts to 45 volts, and in operation varies constantly. Current ranges vary from 20 or 25 amperes to as much as 1,200 amperes. Either direct current or alternating current may be used for welding.

Equipment generally used for welding with alternating current is the transformer type welder. Welding transformers are especially designed to provide control of the welding current through a wide amperage range and to withstand the severe loads of welding service.

The equipment most commonly used for d.c. is a motor generator of the variable voltage type, the motor of the machine being arranged for any commercial power supply. The generator is arranged so that the voltage automatically adjusts itself to the varying voltages demanded by the arc.

In the United States, the first welding machines used were the so-called constant-potential type, which lacked the economies developed in later machines, such as those incorporating the Homrighaus Patent of The Lincoln Electric Company. The Homrighaus Patent covered the design of a single-operator, variable voltage type welder, and made possible great subsequent economies. Current types of welders available include portable, stationary, and welders on skids for mounting in trucks. The variable voltage type welder is comparatively small in size, having easy portability. This factor allows the machine to be easily and quickly placed near the work to be welded, thus eliminating the extensive installation of large size wiring required to bring the welding current to the work. The variable voltage machine is the most widely used, and, at the same time, the most economical type of welder.

Welding Electrodes.—The variety of electrodes available for various steel applications permits accurate matching to the specific job, assuring maximum quality and economy. The various mild steel electrodes may be classified as follows: (1) the method of use, such as working position (flat, vertical, overhead, horizontal); (2) the type of joint, such as fillet or groove; (3) mechanical properties of the deposit, such as tensile strength and ductility and by operating characteristics which vary according to the nature of the covering. These factors are involved in the general classifications assigned to various types of electrodes by the American Welding Society in its "Filler Metal Specifications" for different materials including steel, stainless steel, aluminum, and copper.

G. G. Landis,
Chief Engineer, The Lincoln Electric Company, Cleveland, Ohio.

GAS WELDING

A nonpressure (fusion) welding process wherein the welding heat is obtained from an oxygen-fuel gas flame is known as gas welding.

While oxygen may be used in combination with hydrogen or one of several carbohydrogens, it is combined with acetylene (C_2H_2) for most of the gas welding applications. Although pressure is not usually used for oxyacetylene welding, it is necessary in the related process known as pressure gas welding.

Oxyacetylene welding was impossible until a means was discovered by which acetylene [1] could be produced easily and cheaply. By 1895 when Thomas L. Willson had established facilities to produce calcium carbide, acetylene became recognized as a valuable illuminant and heating gas.

The first oxyacetylene torch was invented by Edmond Fouché, a Frenchman, used experimentally about 1901, and commercially about 1903. This was a high pressure torch, for at that time acetylene was compressed in acetone containing cylinders at several atmospheres of pressure. Inasmuch as both gases were compressed to high pressure it was quite easy to obtain a good mixture of both acetylene and oxygen entering the torch. Later, upon changing positions, Fouché went to work for a company which produced acetylene from low pressure generators and consequently designed a torch that would work on low gas pressures. This torch received its oxygen under high pressure which, upon entering the mixing chamber of the torch, expanded and drew acetylene from the acetylene orifice by the injector principle. These early acetylene torches thus incorporated the principles that are present in our modern low and medium pressure welding torches.

Until Eugène Bournonville, a French inventor, brought the first welding torch to this country in 1906 very little progress was made in any type of gas welding. With the introduction of the welding torch, however, some of the earlier users of welding began to use welding equipment for commercial purposes and a major industry was started.

Oxyacetylene welds are made by using a torch or blowpipe flame to heat the metals to be joined to the melting point. Usually some new metal is added from a welding rod which is melted at the same time and flowed together with the fused metal of the two edges of the joint. The temperature of the flame is from 5800° to 6300°F., being produced by the combustion of the acetylene (or other fuel gas) in oxygen delivered through the torch.

There are two different stages of combustion in the oxyacetylene flame. The first of these is a luminous cone at the tip of which the highest temperature is produced. One part of oxygen to approximately one part of acetylene is delivered through the torch and consumed in the luminous cone or the first reaction of the flame. This combustion produces carbon monoxide and hydrogen which burn in the secondary reaction, obtaining the oxygen from the surrounding atmosphere, and producing carbon dioxide and water vapor.

Equipment.—The apparatus for gas welding consists of a torch, two lengths of hose, and two regulators or reducing valves. One of these is attached to the oxygen cylinder, and the other to the acetylene cylinder or pipe line. When full, the pressure within the oxygen cylinders is approximately 2,000 pounds per square inch, and the pressure in the acetylene tanks about 250 pounds per square inch. Obviously these pressures must be reduced in order to utilize these gases at the torch, and this is the purpose of the regulators. Acetylene must never be used at a pressure in excess of 15 pounds per square inch.

It is important to have regulators with two gauges—one showing the pressure of the gas within the cylinder, the other showing the pressure of the gas within the hose line to the torch. These gauges should always be in good condition. Dangerous pressures in the hose lines can very easily occur through the use of broken or inaccurate gauges.

Types of Torches.—There are a number of different types of torches upon the market designated particularly by the relative pressures of the two gases. For instance, there is the low pressure or injector type torch in which the acetylene is supplied to the torch at a pressure of less than one pound per square inch. This pressure is constant for most sizes of tips. The oxygen pressure, on the other hand, is considerably higher, ranging from 10 to 30 pounds per square inch, or more, depending upon the tip size. The tip is designed with an injector nozzle through which the oxygen passes and draws the acetylene through the torch and into the mixing chamber in the tip. Because of the difference in the pressure of the two gases, it is necessary to have a very small opening for the oxygen through the injector nozzle, and a much larger opening for the acetylene situated adjacent to the mixing chamber.

Equal pressure torches are those designed with equal area inlets to the mixing chamber of the tip for both oxygen and acetylene, because with this type of torch, both gases are delivered from the regulators at equal pressures.

All torches are designed to deliver one part oxygen through the torch for each part of acetylene entering through the acetylene passage. While it is true that 2½ volumes of oxygen are required to completely consume 1 volume of acetylene, only one of these volumes is delivered through the torch, and burns at the tip of the torch to produce the luminous cone of flame; the secondary reaction, or flame envelope, obtains the remaining 1½ parts of oxygen from the surrounding air.

Tip Sizes.—Torch tips are interchangeable in a given torch, and are made in various sizes to produce larger or smaller flames as may be required for the thickness of the metal to be welded. A very light gauge sheet of steel, for instance, requires a very small flame, hence a small tip; while a piece of steel plate one inch thick requires a much larger tip. These various sizes of tips require varying pressures of both oxygen and acetylene, and these pressures are themselves important.

Technique.—As heretofore explained, oxygen and acetylene are delivered through the hose lines to the torch, and are adjusted for either neutral, oxidizing (excess oxygen), or carburizing (excess acetylene) flames, depending upon the metal being welded. The adjustment of the flame is perhaps the most important factor in this welding process.

The torch is ordinarily held in the right hand of the operator. The welding rod, of the correct diameter, depending upon the thickness of the work, is held in the left hand. The rod may be either bent to an angle or held straight. The

[1] Discovered by Edmund Davy, an English chemist, in 1836.

plates or casting to be welded should be prepared by single or double veeing of the edges to be welded, veeing in the shape of a deep U, or in the case of sheet metal, flanging the edges upward, etc.

Welding may proceed either forward (forehand technique) or backward (backhand technique) as desired—that is, away from the operator or toward him. Sometimes the flame is moved in a semicircle (weaving) and the rod is moved in a straight line back and forth immediately ahead of it in alternating motions. At other times the torch is held without side movement, but gradually progressing forward, and all puddling is done with the welding rod in the puddle. Movement will often depend upon the individual operator. The exact technique with reference to the movement of the torch and rod will also depend to a large extent upon the class of work being accomplished, and the kind of rod used. There are several well-recognized methods, all of which will produce satisfactory welds.

Welding Rods.—It is very essential that suitable welding rods be selected for the job at hand. If, for instance, cast iron is to be welded, the rods should be of a grade of cast iron conforming to the requirements of the specifications or of another suitable material (such as a bronze welding rod). If low carbon steel plate is to be welded, the welding rods should be of low carbon steel. If higher carbon or the alloy steels are to be welded, the rod should likewise be an alloy steel, chrome vanadium steel, or molybdenum steel. On the other hand, if the work is brass, bronze, copper, or aluminum, the rods should consist of alloys of these metals.

When nonferrous welding rods or cast iron welding rods are used, it is generally found advantageous to use a fluxing material to improve welding characteristics.

T. B. Jefferson,
Editor, "The Welding Engineer."

RESISTANCE WELDING

Resistance welding was first patented in 1886 by Elihu Thompson. The heat which effects the welding is caused by the electrical resistance of the contacting areas to be welded.

Fundamentals.—The equipment that is required for resistance welding consists of a rigid frame, housing a high secondary current welding transformer; the electrodes for contacting the work; the conductors connecting these electrodes with the welding transformer; means for imposing electrode pressure on the work; means of welding current regulation; a contactor to interrupt the power to the welding transformer; and a timer which is capable of properly controlling the action of the contactor.

The heat or energy being generated in the weld is expressed by the formula $W=I^2Rt$, where W is heat in watt-seconds, I is the current in amperes flowing through the weld, R is the resistance in ohms, and t is the time in seconds. Thus, resistance factors affecting the amount of heat being produced by a given welding current for a unit of time are: (1) the electrical resistance of the materials being welded; and (2) the contact resistance between weldments as determined by surface condition, scale, welding pressure, and other such factors. A great number of metal elements and alloys have been satisfactorily welded in production. Low carbon steel is easily welded. Copper and aluminum alloys are more difficult to weld because of their lower electrical resistance, which necessitates a much greater welding current to obtain satisfactory fusion.

Spot Welding.—This type of resistance welding unites two or more sheets of metal, producing a lap joint by concentrating the welding current and pressure on the materials by means of relatively small electrodes. A press type welder is one in which a slide, carrying the upper electrode holder, moves vertically on antifriction bearings when operated by an internal air cylinder. Means are provided for vertical and horizontal adjustment of the lower arm position, and for adjusting the operating stroke of the upper electrode assembly. Air Pressure regulators and gauges are built in the upper arm structure. Equipment for controlling the magnitude of the weld current and the length of the weld time are enclosed in the frame. Operation of the machine is fully automatic, closing and separating the welding electrodes at prescribed intervals as long as the foot switch is depressed by the operator. The three transformers supply the low voltage welding current to a special secondary switching device which conducts the welding current output from each transformer to the electrodes in sequence. This machine is capable of welding an assembly completely in five seconds. Usually, welding machines of this type are specially built for the welding of only one type of assembly, and are justified by their high rate of production. The electrodes of any resistance welding machine are of prime importance, because of their influence on both production quality and operating cost. Electrode materials must carry large currents without burning or blistering, and must also have considerable mechanical strength in order to withstand the high welding pressures and repeated impacts on the materials being welded. Since the face of the electrode becomes quite hot in operation, it is desirable that it have a high annealing temperature. Strong, high-conductivity copper alloys are available in many degrees of hardness.

Seam Welding.—This process is very similar to spot welding, except that, in seam welding, the stud type electrodes of spot welding are replaced with welding wheels which roll along the work and produce a series of overlapping spot welds to form a continuously closed joint. The rate of seam welding is usually from 2 to 100 feet per minute. At the higher speeds, the current application is continuous, each half cycle of alternating current producing a small weld overlapping the previously formed weld to form a continuous seam. When welding at lower speeds, it is desirable that the welding current be interrupted so as to provide a cooling time for the solidification of each individual spot. Adjustments for welding current, pressure, speed, and operating stroke are provided on the machine. By use of the insert type mandrel the machine may be converted to "circular" welding, wherein the wheels are turned 90 degrees. The same machine can thus be used for welding the longitudinal seams and end seams of a cylindrical container.

Projection Welding.—This variant type of resistance welding is one in which localization of pressure and current is accomplished by means of embossments on one or both of the parts being welded. These embossments permit the use of flat or plain electrodes, or dies, on the welding machine. It is often possible to make

all projection welds necessary to accomplish the assembly of the two "parts" or "weldments" in one operation. Projection welding usually offers the most rapid assembly method of any of the resistance welding processes.

Flash Welding.—In this process the two parts are loaded in the machine slightly separated. After clamping by the electrodes, the power is turned on, applying the welding voltage between the weldments and initiating the travel of the movable platen at the same time. When contact is established between the parts, the voltage across these parts is sufficient to cause a sparking, or flashing, which throws off molten particles of metal. This flashing continues, as the moving platen goes slowly forward, until the entire area to be welded is flashing vigorously. When the heat from this flashing has rendered the parts sufficiently plastic, they are suddenly "upset," or pushed together. This contact squeezes out any burned metal, slag, oxide, or other impurities which would otherwise weaken the weld joint. Immediately following this upset movement, the power is interrupted, allowing the weld to cool.

Resistance Welding.—*Application.*—Resistance welding processes are best suited to mass production of sheet metal assemblies less than ¼ inch in thickness. The most important factors governing the choice of welding equipment are: (1) required production speed, and (2) total quantities involved. High production justifies the use of special equipment, higher in first cost, but lower in operating cost, and producing at a higher rate of speed. Special machines are usually amortized over a short period of time ranging from one to five years. The more standard types of equipment are expected to be utilized on future welding jobs, so that their useful lives may be from five to fifteen years. The actual power cost for operation of the machine is usually insignificant in the total consideration, because of the very short time required for the performance of a weld. The power demand of the welding machine, however, at times necessitates the installation of additional power supply equipment. Because of the short welding time (as low as .01 second), discoloration, burning, and weakening of the material is largely eliminated.

Foster R. Woodward,
Sales Engineer, Taylor-Winfield Corporation, Warren, Ohio.

OTHER WELDING PROCESSES

Among the welding processes used for fewer applications, but no less important in their place are Forge Welding, Thermit Welding, Flow Welding and Induction Welding.

Forge Welding.—Basically forge welding is the method of the blacksmith shop. It involves the application of heat by a furnace and the application of pressure by hammer blows. Although quite commonly used before the advent of arc welding for certain types of pressure vessels and other similar applications, forge welding is little used today except for special applications such as the cladding of steels which is known as *roll welding* and the fabrication of pipe which is known as *die welding*. *Hammer welding,* the third process in this group, is used for some hardware manufacture and by the railroads in the safe ending of boiler flues.

Thermit Welding.—Thermit, as employed for welding, is a mechanical mixture of finely divided aluminum and iron oxide in the form of magnetic iron scale roughly in the proportion of one to three. The temperature resulting from the ignition of this thermit mixture is about 5000°F. or more. Additions are made to this basic thermit mixture to affect the temperature or to alter the chemical composition of the resultant weld.

The thermit reaction is started by means of an ignition powder containing barium peroxide. This reaction occurs in a suitably designed crucible which is tapped when the metal becomes molten. This molten metal flows into the area to be welded which has been formed by a wax pattern and around which a suitable mold has been formed. In these steps, thermit welding very largely resembles usual casting procedures.

Of the two thermit processes, *pressure thermit welding* and *nonpressure thermit welding,* the latter is by far more commonly employed. Pressure thermit welding is used mostly for the welding of pipe.

While originally used for the repair of heavy castings and forgings, nonpressure thermit welding has come to be used in new fabrication as well, particularly in the production of very large castings by welding two or more small cast sections together. During World War II, the stern frames of ships were fabricated this way. Thermit welding is also used in joining the tracks of street railways and overland railroads eliminating the existence of joints, thereby increasing the smoothness of the ride.

Flow Welding.—Except for special applications this is a relatively uneconomical process of welding and finds little general use. In this process molten filler metal is poured over the joint to be welded thereby heating the parts and at the same time providing the filler metal to fill the joint. The most common application of flow welding is the repair of cast manganese bronze propeller blades. This process is sometimes called "burning in."

Induction Welding.—This is a relatively new process and its use has not been explored too much to date. The principle involved in induction welding is the heating of metal by means of an induced electric current produced by placing the part in a magnetic field. High-frequency current ranging from 300 cycles per second up to as high as 2000 cycles per second is used. Present applications involve the welding of steel sheet and wire ranging in thickness from 0.010 inch to about ⅜ inch. Shapes welded have been generally round or oval; other shapes can be welded if provision is made in the design of the equipment to secure uniform distribution of the heat.

Simon A. Greenberg.

BRAZING

Brazing is a metal joining process, the origin of which has been lost in antiquity. Closely related to welding (q.v.), it is distinguished from the other welding processes by the following standard definition of the American Welding Society: "A group of welding processes wherein coalescence is produced by heating to suitable temperatures above 800°F. and by using a nonferrous filler metal having a melting point below that of the base metals. The filler metal is distributed in the joint by capillary attraction."

Comparing brazing and other welding processes, it will be noted that (1) brazing does not

involve melting of the base metal parts, whereas this is necessary for welding; (2) a closely fitted joint is required to enable movement of the molten brazing metal (filler metal) by capillary attraction, whereas this is absent in welding. Since brazing metals, (called brazing alloys) by themselves, exhibit low strength, closely fitted joints are used so that the film of brazing metal will be thin. Further, good practice dictates the use of lap type joints rather than butt joints.

Virtually all metals and alloys which melt above 800°F. can be brazed with one or more of the available alloys. In order to achieve low melting temperatures, alloys are generally employed except in the case of copper which is used in the commercially pure form. Some of the more common types of brazing alloys together with the approximate ranges of operating temperatures are listed herewith: magnesium brazing alloy, 800°-1000°F.; aluminum brazing alloy, 1000°-1200°F.; silver brazing alloy, 1100°-1600°F.; brass (spelter) brazing, 1600°-1900°F.; copper brazing, 2000°-2100°F. Magnesium and aluminum brazing alloys are suitable only for brazing metals of similar composition. However, the other types, because of their low melting points are frequently used for joining dissimilar metals. Careful cleaning before brazing and the use of chemical fluxes during brazing are necessary to assure sound brazed joints.

The means of heating provides the distinction between the eight common processes of brazing which are torch, induction, furnace, dip, resistance, block, flow and twin-carbon arc. In torch brazing, a gas flame, usually oxyacetylene, is used to heat the parts and flow the alloy. Induction brazing derives its heat from a high frequency electric current induced in the parts to be brazed. Furnace brazing may be performed in either electric or gas fired furnaces, with or without protective furnace atmospheres. Dip brazing involves the use of molten baths of either brazing alloys or salts; the former provides the brazing alloy while the latter merely supplies the heat (and sometimes the flux) with the alloy introduced separately. Resistance to the passage of low voltage and high currents furnishes the heat in resistance brazing; standard resistance welders, modified, are generally employed. Large massive, metal blocks, heated separately in a furnace supply the heat for block brazing. In flow brazing, molten brazing alloy is flowed over the parts to be brazed thus furnishing the necessary heat. An electric arc between two carbon electrodes develops the heat for twin-carbon arc brazing.

Brazing as an industrial production technique finds applications in such widely diversified fields as plumbing, heating, machine tools, instruments, steel mills, railroads, sporting goods, jewelry and many others.

Mechanical Engineer, Air Reduction Sales Company.

WELDON, Richard Chapman, Canadian legislator and educator: b. Sussex, New Brunswick, Jan. 19, 1849; d. Nov. 27, 1925. After practising law he was dean of Dalhousie's law faculty (1883–1914). From 1887 to 1896 he was also a member of Parliament.

WELFARE ISLAND, a part of New York City's Manhattan Borough, in the East River. Extending about a mile and three quarters, its southern point is opposite 51st Street and the northern opposite 86th Street, Manhattan. It is the site of numerous municipal welfare institutions. Gov. Wouter Van Twiller in 1637 purchased it from the Indians. Acquired in 1668 by Capt. John Manning, after his death it passed to his stepdaughter, Mrs. Robert Blackwell, and was called Blackwells Island. In 1828 the city purchased it from the Blackwell family, and in 1921 renamed it Welfare Island.

WELL-TEMPERED CLAVIER, The (Ger. *Das Wohltemperirte Clavier*), the celebrated collection of 48 preludes and fugues composed by Johann S. Bach, 1685–1750 (q.v.) to test the system of equal temperament in tuning. For this purpose he wrote a prelude and fugue in each key, the keys following one another not in relation, but in the order of chromatic ascent. See also MEANTONE; TEMPERAMENT.

Consult *Grove's Dictionary of Music and Musicians,* vol. 5, pp. 746, 747 (New York 1935).

WELLAND, city, Province of Ontario, Canada, county seat of Welland County. Incorporated as a village in 1858, two years after the erection there of the county buildings, Welland was incorporated as a town in 1878, and as a city in 1917. The Welland Ship Canal, connecting Lake Erie and Lake Ontario, runs through the center of the city, which is also served by the Canadian Pacific; Canadian National; Michigan Central; Wabash; Pere Marquette; Toronto, Hamilton and Buffalo; and Niagara, St. Catherines and Toronto (electric) railways. Industries include iron and brass foundries, boiler works, cordage works, cotton mills, and the manufacture of agricultural implements, light and heavy forgings, rubber goods, electrical equipment, steel, overalls, fertilizers, etc. The city maintains an up-to-date fire department, and has one of the most modern waterworks systems in Canada. It has an excellent public school system, including a high and vocational school; a number of banks; a public library; parks and athletic fields. There are United, Presbyterian, Baptist, Anglican and Roman Catholic churches. Welland County General Hospital is located here. Welland's growth has been steady. In 1871 its population was 1,110; in 1881, 1,870; by 1911 it had increased to 5,318 and by 1951 to 15,382.

WELLAND SHIP CANAL. See under CANADIAN CANALS.

WELLER, Reginald Heber, American Protestant Episcopal bishop: b. Jefferson City, Mo., Nov. 6, 1857; d. Nov. 22, 1935. He studied at the University of the South 1875–1877, and was graduated from the Nashotah Theological Seminary, Wisconsin, in 1884. Ordained to the priesthood, he was rector of Eau Claire, Wis., 1884–1888; of Waukesha, Wis., 1888–1890 and of Stevens Point, Wis., 1890–1900. He was consecrated bishop-coadjutor of Fond du Lac on Nov. 8, 1900, the somewhat spectacular ceremonial practiced on this occa-

sion calling forth some criticism; and succeeded as bishop Aug. 30, 1912. He died at Jefferson City, Mo., Nov. 22, 1935.

WELLES, wĕlz, **Gideon,** American political leader: b. Glastonbury, Conn., July 1, 1802; d. Hartford, Conn., Feb. 11, 1878. He studied at Norwich, Vt., in the academy which later became Norwich University, but did not complete the course there, and for a time turned his attention to the study of law. In 1826, however, he entered journalism as editor of the Hartford *Times,* which under his management became one of the leading Democratic papers of the state. He was one of the first publicly to advocate Andrew Jackson's election to the presidency, and always warmly supported him. In 1827–1835 he was a member of the Connecticut legislature, and both as legislator and editor advocated the abolition of imprisonment for debt, opposed the practice of special legislation, and succeeded in obtaining the passage of general laws for the incorporation of business corporations. In 1836 he resigned the editorship of the *Times,* but continued to write for that paper. In 1835, 1842, and 1843 he was chosen state comptroller; in 1836–1841 he was postmaster of Hartford; and in 1846 was appointed chief of the bureau of provisions and clothing in the Navy Department, which office he held till 1849.

He had always been opposed to the extension of slave territory, and on the organization of the Republican Party in 1855 became identified with it, and was Republican candidate for governor of Connecticut in 1856, and a member of the national committee. In 1861 he was appointed secretary of the navy, and conducted the affairs of his department with marked executive ability throughout the Civil War; he continued in office under President Andrew Johnson till 1869. He was later affiliated with the Liberal Republicans, and in 1876 was a supporter of Samuel S. Tilden. He was author of *Lincoln and Seward* (1874). The *Diary of Gideon Welles* (3 vols., 1911) is an important historical document.

WELLESLEY, wĕlz'lĭ, **Arthur.** See Wellington, Arthur Wellesley, Duke of.

WELLESLEY, Richard Colley (1st Marquis Wellesley), British statesman: b. Dublin, June 20, 1760; d. London, Sept. 26, 1842. He was educated at Oxford, and on his majority took his seat as earl of Mornington in the Irish House of Peers. Three years after, he was returned to the British House of Commons as member for Beeralston, and afterward sat for Windsor (1787–1796), and for Old Sarum (1796–1797). He was appointed governor general of India in 1797, and in 1799 created Marquis Wellesley in the Irish peerage. His administration was notable, both for its ability and the large accessions of territory made under it by the conquest of Mysore and the humbling of the Mahrattas. In 1809 he became foreign secretary under Spencer Perceval. In 1812 he resigned his place chiefly because he was in favor of Catholic emancipation, and did not return to office till 1821, when he became lord lieutenant of Ireland. This post he retained till 1828, when he was removed from it by his brother, the duke of Wellington, who was an opponent of emancipation and had become prime minister. In the Grey ministry he held the office of lord steward till 1833, when he again became lord lieutenant of Ireland. Displaced in the following year by the Peel ministry, he afterward held the office of lord chamberlain for a few months in 1835.

Consult Owen, S. J., ed., *Selections of Dispatches* (1877); Hutton, W. H., *Lord Wellesley* (1893); *The Wellesley Papers: Life and Correspondence of Richard Colley Wellesley,* 2 vols. (1914).

WELLESLEY, town, Massachusetts, in Norfolk County; altitude 140 feet; 12 miles southwest of Boston; on the New York Central Railroad. It is principally a residential and college town, with many broad streets and handsome residences. Wellesley College (q.v.) and Dana Hall, a preparatory school for girls, are located here. Within the boundaries of Wellesley College campus lies Lake Waban. The town has a public library. Babson Institute is located in Wellesley Hills. The few industrial establishments manufacture electrical machinery, hosiery, building supplies, and paper boxes. The first white settlement was made here about 1660. In 1704 a sawmill was set up, and later other industries were developed. Wellesley was set off from Needham and incorporated in 1881. The township includes the villages of Wellesley Hills and Wellesley Farms. Government is vested in a town meeting and a board of selectmen, elected annually. Pop. (1940) 15,127; (1950) 20,549.

WELLESLEY COLLEGE, a college for women located in Wellesley, Mass., about 12 miles from Boston. It was founded by Henry Fowle Durant to give "to young women opportunities for education equivalent to those usually provided in colleges for young men." The charter was obtained in 1870, and the college first opened to students in 1875. It is nonsectarian in control; three representatives of the alumnae serve on the board of trustees. In 1894 the system of elective courses was established, which with some modifications is still in force. The college confers one baccalaureate degree, B.A., and the graduate degrees of M.A., M.S. in education, and M.S. in hygiene and physical education. Certain courses are required in hygiene, biblical history, English and speech; in addition, each candidate for the degree must complete within the 120 semester hours, required 12 semester hours in each of three groups of subjects (art, music and language; social sciences; mathematics and science) and 42 semester hours in one field of concentration. Required courses and courses counted for distribution may be included in the concentration, in which a major of 24 to 30 hours must be in one department, 18 to 12 in one or more other departments supplementary to the major. Pedagogical courses are offered in the history and principles of education and in method of teaching; art and music are included in the curriculum. The college contributes toward the support of the American School of Classical Studies in Athens, the American School of Classical Studies in Rome, and the Marine Biological Laboratory at Wood's Hole. Scholarships are available for undergraduates, and both fellowships and scholarships for graduate students of recognized ability. In 1946 the Wellesley Institute for Foreign Students was established for the purpose of orienting those foreign students accepted by American colleges and universities. The Wellesley Summer Theater and School was established in 1947.

The campus has a particularly beautiful situation within the limits of the town; it includes a lake which affords excellent opportunity for rowing and skating. The older buildings include the Farnsworth Art Building, Whitin Observatory, Houghton Memorial Chapel, the Library, Billings Hall for Music, Mary Hemenway Hall for physical training, the President's House, Simpson Infirmary, Page Memorial Kindergarten, and 20 halls of residence. Among the newer buildings are the Recreation Building, Sage Hall for botany and zoology, and Pendleton Hall for physics, chemistry, and psychology. The library of over 200,000 volumes has the famous Plimpton Collection of Italian books and Renaissance manuscripts, the Ruskin Collection, and rare editions of English poetry. Enrollment (1947–1948) 1,723.

WELLESLEY ISLANDS, Australia, in Gulf of Carpentaria are politically attached to Queensland. Mornington, the northernmost and largest island, is 40 miles long by 15 miles broad.

WELLHAUSEN, vĕl'hou'zĕn, **Julius,** German Orientalist and Biblical scholar: b. Hameln, Westphalia, May 17, 1844; d. 1918. He studied theology in the University of Göttingen, in 1872 was appointed professor of theology in Greifswald University, but resigned in 1882 because he could no longer hold the accepted views of Scriptural inspiration. He went to Halle as extraordinary professor of Oriental languages and in 1885 was appointed to an ordinary professorship at Marburg, whence in 1892 he removed to Göttingen to occupy a similar post. In 1871 he published a text-critical work on the books of Samuel, and in 1874 appeared his treatise *Die Pharisäer und Sadducäer.* The first volume of *Geschichte Israels* was issued in 1878 and a second edition of it in 1883, under the title, *Prolegomena zur Geschichte Israels* (5th ed., 1899). *De Gentibus et familiis Judaeis* (1870); *Der Text der Bücher Samuelis untersucht* (1871). His masterly treatise on *Die Komposition des Hexateuchs und der historischen Bücher des Alten Testaments* (1885; 3d ed. 1899) originally appeared in the *Jahrbücher für Deutsche Theologie* (1876–77). Later works are *Muhammed in Medina* (1882); *Der Arabische Josippus* (1897); *Reste arabischen Heidentums* (2d ed. 1897), first published in the *Skizzen und Vorarbeiten; Die Kleinen Propheten übersetzt, mit Noten* (1892; 3d ed. 1898); different books on the evangelists (1903–08); *Einleitung in die drei ersten Evangelien* (1905; 2d ed. 1911); and *Kritische Analyse der Apostelgeschichte* (1914).

WELLING, James Clarke, American educator: b. Trenton, N. J., July 14, 1825; d. Hartford, Conn., Sept. 4, 1894. He was graduated from Princeton in 1844, was appointed associate principal in the New York Collegiate School in 1848 and in 1856–1865 was literary editor of the Washington *Daily National Intelligencer.* He was clerk of the United States Court of Claims in 1862–1867, in 1867–1870 was president of Saint John's College, Annapolis, Md.; occupied the chair of belles-lettres at Princeton in 1870–1871; and in 1871–1894 was president of Columbian College, Washington, D.C. He was a regent of the Smithsonian Institution, president of the Corcoran Gallery of Art and also of the Philosophical and the Anthropological Societies of Washington. While president of Columbian College (now George Washington University), he taught courses in history and international law. His *Addresses, Letters, and Other Papers* were published posthumously in 1903.

WELLINGBOROUGH, England, urban district and town in Northamptonshire, 10 miles northeast of Northampton. It is situated at the junction of several railway lines and serves as a market town for the surrounding agricultural area. There are metal and leather industries. Old buildings in the town include St. Luke's Church, a Norman and Gothic structure, and a grammar school founded in 1595. Pop. (est. 1947) 28,571.

WELLINGTON, Arthur Mellen, American civil engineer: b. Waltham, Mass., Dec. 20, 1847; d. New York, May 16, 1895. Defective eyesight prevented his entering a university but he studied civil engineering under Prof. J. B. Henck in Boston. He was later associated with the laying out of Prospect Park, Brooklyn, and from 1868 was a railroad engineer. In 1881–1884 he was chief engineer of the Mexican National and the Mexican Central railroads. He was the author of the plan for multiplying the traffic facilities of Brooklyn Bridge by five times, recommended by the Board of Experts in 1887. In 1884–1887 he was an editor of the *Railroad Gazette;* and from 1887 until his death he was one of the editors and owners of the *Engineering News.* He was also active as a consulting engineer in many important public works, among them the plans for the Boston subway and the abolition of grade crossings in Buffalo. In addition to numerous articles, he published *Methods for the Computation from Diagrams of Preliminary and Final Estimates of Railway Earthwork* (1874); *The Economic Theory of the Location of Railways* (1877); *Field Work of Railway Location and Laying out of Works* (1889).

WELLINGTON, Arthur Wellesley, DUKE OF, British soldier and statesman: b. 1769; d. Walmer Castle, England, Sept. 14, 1852. He was the fourth son of the 1st earl of Mornington. His mother was the eldest daughter of the 1st Viscount Dungannan. He was educated at Eton, privately at Brussels, and finally at the Military College of Angers. On March 7, 1787 he received a commission as ensign in the 73d Foot. He was gazetted under the name of Wesley, the family name till changed by his brother to Wellesley. After a rapid series of changes and promotions he attained by purchase in September 1793 the command as lieutenant colonel of the 33d Regiment in which he had attained his majority in April of the same year. In 1790 he was returned to the Irish Parliament for the family borough of Trim, in the county of Meath. In May 1794 he sailed with his regiment for Flanders to join the army of the duke of York. In 1796 he joined his regiment at the Cape, arrived at Calcutta in February 1797, and was attached to the Bengal service. Later the 33d Regiment was attached to the Nizam's contingent in the Deccan with Wellesley in command. The army

entered Mysore in March 1799. An engagement took place at Mallavelly on the 27th, in which Wellesley, who commanded the left wing, turned the right of the enemy. He was subsequently employed to dislodge the enemy from their posts in front of Seringapatam and after the capture of that capital was appointed July 1799, to its command. During his administration he was compelled to take up arms against Dhundiah Waugh, a robber chief, who styled himself "King of the Two Worlds." Wellesley overtook and routed him with a small body of cavalry 10 Sept. 1800. In April 1802 Wellesley attained the rank of major-general. Early in 1803 he was appointed to the command of a force destined to restore the Peishwa of the Mahrattas, driven from his capital by Holkar. This operation successfully performed, the other Mahratta chiefs, Scindia and the Raja of Berar, showed hostile designs against the British and Wellesley was appointed to the chief military and political command in the operations against them. After an active campaign, in which he took Ahmednagar and Arungabad, he encountered a powerful Mahratta army, assisted by French officers, at Assaye (23 September) and entirely defeated it. The parallel successes of General Lake, and the defeat of the Raja of Berar by Wellesley at Argaum on 29 November, compelled the submission of the Mahrattas and peace was restored on conditions drawn up by the successful general. The fame of Wellesley's achievements had now spread over India. Before leaving Madras he received his appointment as K.C.B., and the thanks of both houses of Parliament. He sailed for England on 10 March 1805 and arrived in September.

On 10 April 1806 Wellesley married Lady Catherine Pakenham, third daughter of the Earl of Longford. He had previously been elected and distinguished himself in the House of Commons by the defense of his brother's administration in India. In April 1807 he was appointed chief secretary for Ireland and in August received the command of the reserve in the expedition to Copenhagen under Lord Cathcart and Admiral Gambier. He took Kioge 29 April, the only land operation of importance. On returning he resumed his duties as secretary and received the thanks of Parliament for his share in the expedition. On 25 April 1808 he attained the rank of lieutenant-general.

In June, Wellesley received the command of a force destined to operate in the north of Spain and Portugal in aid of the revolt against Napoleon. On 30 July he anchored in Mondego Bay, and landed his troops at Figueira. The English began their southward march on 8 August. Wellesley moved on the coast road to Torres Vedras. At Roliça he encountered about 5,000 men under Delaborde, whom Junot had sent in advance to arrest his progress. This corps, after a spirited resistance, was driven back and retired to Torres Vedras. Wellesley now drew nearer the coast, reaching Vimeiro on the 19th, where he was reinforced by two brigades from England, raising his force to 17,000. At the same time he was superseded in the command. The government had determined to increase their army in the Peninsula, and had appointed Sir Hew Dalrymple to the chief command, with Sir Harry Burrard as second and Wellesley, Moore, Hope, Paget and Fraser as divisional commanders. Junot determined to attack the English on the land side while they were in the immediate neighborhood of the sea. The attack was made on 21 August and Junot was beaten. After the battle Junot proposed an armistice, the result of which was the famous Convention of Cintra, by which the French agreed to evacuate Portugal on condition of being conveyed to France with their arms and baggage. Public feeling in England over the excessive liberality of the terms ran so high that the generals were recalled to be examined by a board of inquiry, but their conduct was approved of and commended. Wellesley proceeded to Ireland in December as chief secretary, and early in 1809 received the thanks of both houses of Parliament for his conduct of the campaign.

In the latter part of 1808 Napoleon overran Spain with 200,000 men, and Sir John Moore, pursued by Soult, carried the British army to Coruña, where it embarked for England. Lisbon was still held by Sir John Cradock and a British force occupied Cadiz, when Wellesley was appointed to assume the chief command in the Peninsula. He arrived at Lisbon 22 April 1809. He advanced againt Soult at Oporto and the French were thrown into confusion and retreated precipitately. Soult now retired to Galicia, followed by Wellesley to the frontiers of Portugal and harassed by the insurgent Portuguese. The Peninsula was at this time occupied by about 250,000 French troops; but after the departure of Napoleon the independence or insubordination of the French marshals prevented effective co-operation of the different armies, and the French command never extended beyond the districts occupied by their armies. The British commander had a series of difficulties to contend with. First was the smallness of the armies on which he could rely. The numbers of the British were always comparatively insignificant and reinforcements were slowly and scantily supplied. Almost as formidable was the difficulty of co-operating with his allies. Spain and Portugal were without regular governments. The Portuguese officers had mostly fled to Brazil, but the Portuguese troops carefully drilled by Beresford and placed under the command of British officers, soon became a tractable and efficient force. It was far otherwise with the Spaniards. The junta and the generals were alike ignorant, incompetent and self-conceited and with the raw levies which constituted the Spanish armies it was positively dangerous to co-operate. Even with the Portuguese government, Wellington (as he must now be called) had natural but formidable difficulties to contend with. The subsistence of the armies was a constant source of danger and embarrassment both in Spain and Portugal. The resources of the country were oppressed by the armies of three nations. The French took all they wanted and wasted much more. The Spanish armies, numerous and inefficient, were a sufficient weight for the junta, which always supplied with reluctance the wants of the British who had commonly much greater

difficulty in procuring provisions for money than either of the other armies had in seizing them. Through all these difficulties Wellington adhered with undeviating patience and constancy to the strict principles of discipline he had laid down. He remonstrated with herculean labor, and with admirable spirit, as his dispatches show, with authorities of all kinds; but he never under the great temptation took, or suffered others to take, violent means to supply his most pressing wants.

By a misunderstanding between Soult, who held the command in the north of Spain, and Ney, who was under him, Galicia was evacuated by both marshals and never afterward recovered, a valuable result of Wellesley's first campaign. To co-operate with the Spanish armies, Wellesley had determined to advance into Spain, which he did in July by the north of the Tagus. Nearly every important fortress in Spain was in the hands of the French.

The victory of Talavera, 27–28 July, earned Wellesley the titles of Baron Donro and Viscount Wellington. Next day the French retreated across the Alberche and broke up their army. The first invasion of Spain had resulted in nothing but a series of movements among the French troops. Wellington at this time surveyed the lines of Torres Vedras and formed his plan of fortifications for their defense. Anticipating that invasion would come from the north, he left General Hill to guard the Tagus and fixed his headquarters at Viseu.

The French in the meantime were largely reinforced. Soult was in Andalusia with 60,000 men threatening the south of Portugal, while in the north the army of Portugal was concentrating to the extent of 70,000 to 80,000, and the veteran Masséna was appointed to command it. Wellington was able to bring into the field from 50,000 to 60,000 British and Portuguese troops. The French invested the Spanish fortress of Ciudad Rodrigo early in June and took it on 10 July. They then advanced to the Coa, from which the British retired. Almeida was captured on 27 August. Wellington fell back on the valley of the Mondego. In the middle of September, Masséna began his march down the right bank of the river. At the Sierra de Busaco, a high ridge in front of Coimbra, Wellington made a stand and repulsed the French. After the battle, Masséna turned Wellington's position, who retreated to Leiria, where he halted two days. On 8 October he entered his lines, just as the autumnal rains were beginning to fall. A powerful fleet and a flotilla of gunboats on the Tagus contributed to their defense. Masséna was wholly unprepared for his reception and after some vain demonstrations he retired from their front. The Portuguese parties had cut off his communications with Spain and sickness was rapidly diminishing his numbers. On 15 November he fell back to Santarem.

Napoleon recommended to waste the English with continual engagements of advanced guards and sent Soult instructions to co-operate with Masséna. But Soult, with the blockade of Cadiz and with the Spaniards on his hands, could only spare a sufficient force to besiege Badajoz. In March 1811 Masséna was compelled to begin his retreat, which he conducted with great skill. The French crossed the Agueda on 6 April. Wellington estimated their loss in the campaign at not less than 45,000. Wellington blockaded Almeida and cantoning his army between the Coa and the Agueda, returned to Badajoz, which had been taken by Soult and invested by Beresford. He was speedily recalled by an aggressive movement of Masséna to relieve Almeida. Wellington took up a position to cover the fortress at Fuentes de Onoro, where he was attacked by Masséna with a superior force. In this battle he performed the exceedingly critical operation of changing his front in presence of the enemy. The manœuver was successful and Masséna was repulsed. Almeida surrendered a few days after the battle and Masséna was about the same time superseded by Marmont. Soult in the meantime had been defeated by Beresford at Albuera in an attempt to relieve Badajoz. Wellington returned to prosecute the siege and Marmont also moved south to join Soult, but afterward returned to Salamanca. This induced Wellington to push the siege of Ciudad Rodrigo in preference to that of Badajoz and he returned to the Agueda. Marmont, however, advanced with a superior force and he withdrew to the Coa. Marmont returned to Salamancas.

During the winter Wellington continued to occupy himself with preparations for this siege, collecting his stores at Almeida under pretext of repairing it. On 6 Jan. 1812, he moved his headquarters to Gallegos, invested Ciudad Rodrigo on the 8th and took it by assault on the 12th. An earldom, a pension and a Spanish dukedom awarded this achievement. Wellington now went south with his principal force to take Badajoz; and Marmont, who had collected his forces to raise the siege of Ciudad Rodrigo, invaded Portugal by Sabugal and ravaged the country. Badajoz was taken on 6 April, with a heavy loss. Having secured the frontier fortresses, Wellington determined again to invade Spain. Leaving Hill on the southern frontier he moved north with his main army and on 17 June reached Salamanca, Marmont retiring to Toro. The French general, when he had concentrated his forces, attempted by a series of pretentious manœuvres to surprise the British commander, his ultimate object being to cut him off from his communications. With this purpose he crossed the Tormes, followed by Wellington, who took up his position between the river and two hills called the Arapiles. Here Marmont's overdisplay of tactics recoiled on himself. Having gained the outer Arapile, in extending his left to attack the British right, he gave Wellington the opportunity he had long desired of attacking him. Marmont was wounded and the French left and centre broken. Clausel, who attempted to re-form the army, was routed. Numerous prisoners were taken by the cavalry in pursuit and the French retired to Burgos. Wellington reached Valladolid on 31 July and turning on Joseph, who had advanced to support Marmont, followed him to Madrid, which he entered on 12 August. Hill was now advancing to join Wellington and Joseph fell back from Toledo to Almansa in Murcia. These successes compelled Soult to abandon Andalusia and an Anglo-Spanish force from Cadiz took Seville. Wellington's next movement was against the army he had defeated under Clausel, which had been largely reinforced. He left Hill in Madrid (1 September) and advanced to Burgos, being joined on his

way by a body of Spaniards. The French retired, leaving a garrison in the castle, which Wellington deemed it necessary to take before advancing. The siege, for want of proper artillery, occupied him till 21 October. In the meantime the northern army under Souham was again advancing and Soult with a powerful army marching on Madrid, which Hill had abandoned to fall back on Salamanca. Wellington abandoned the siege and retreated, closely followed by the French, who repeatedly attacked his rear. At Palencia he was joined by a brigade from England. At Tudela, Souham halted to wait for Soult and Wellington proceeded to the Tormes, where he was joined by Hill, and when the French crossed the Tormes in force he took up his old position at the Arapiles. The united armies of Soult and Souham amounted to nearly 90,000 men. Wellington's strength was over 50,000. The enemy, instead of attacking, threatened his communications, upon which he retreated to the Agueda and established his headquarters at Ciudad Rodrigo. The French, not being prepared to invade Portugal, withdrew their armies to cantonments in Castile. General Hill's corps continued to occupy Estremadura and the rest of the British were cantoned on the Portuguese frontier.

The gains of this campaign were substantial. The French had not only been compelled to reinforce their Spanish armies largely at the expense of their operations elsewhere, but had lost Andalusia and given the British a footing in Estremadura. Wellington received (18 August) the title of marquis and Parliament voted him thanks and £100,000. The failure of the Russian campaign compelled Napoleon to recall Soult from Spain and Wellington was able to open the campaign of 1813 with a force of 70,000 British and Portuguese. He had also been appointed commander-in-chief of the Spanish armies. He opened the campaign in May by an advance in the former direction and on 12 June reached Burgos, the French retreating to the Ebro. Wellington turned their position by crossing the Ebro near its source and after some unsuccessful fighting they fell back on Vittoria. In a strong position commanding the principal roads through the town they were defeated by the British on 21 June. Being driven from the town, while the British left had seized the Bayonne road, by which they retreated, they were thrown into confusion and routed. Wellington now occupied the passes of the Pyrenees and besieged Pampeluna and San Sebastian. He was created field-marshal and received the Spanish title of Duke of Vittoria. Soult was dispatched by Napoleon, with the title of lieutenant of the emperor, to restore matters in the Peninsula. He had still a powerful army (80,000), but after a series of engagements, called the battles of the Pyrenees, he retreated into France. Some time being spent in pushing the sieges of Pampeluna and San Sebastian, the former of which surrendered 31 August, the latter 31 October, Wellington crossed the Bidassoa in October and in November the whole army descended from the Pyrenees into the French plains. Some severe fighting occurred before the armies went into winter cantonments. On 27 February Wellington defeated Soult at Orthez and the French retreated to Toulouse. Suchet had abandoned Catalonia and reached Narbonne. Another engagement took place in front of Toulouse on 10 April, in which the French after severe fighting were driven into the town. Next day, Soult evacuated Toulouse and Wellington entered it on the 12th. In the afternoon news arrived of Napoleon's abdication, but Soult declined to submit to the provisional government without further advice and Wellington refused an armistice. Advices having arrived from Berthier, Soult entered into a convention on 18 and Suchet on 19 April. In a sortie of the garrison of Bayonne, before the peace was known, the British suffered severely. On 30 April Wellington, leaving his army in quarters, set out for Paris. In May he had to visit Madrid to allay political differences among the Spanish generals and on 14 June he issued farewell orders to his army. He was created Marquis of Douro and Duke of Wellington in May, with an annuity of £13,000, commutable for £300,000, afterward £400,000. He received the thanks of both houses of Parliament. In July he went as Ambassador to France and he succeeded Lord Castlereagh as British representative in the Congress of Vienna. In April he took the command of the army assembled in the Netherlands to oppose Napoleon. (See FRANCE; NAPOLEON I; WATERLOO). On his return to England after the restoration of peace he received a vote of £200,000 for the purchase of the estate of Strathfieldsaye, to be held on presenting a colored flag at Windsor on 18 June each year. Numerous foreign honors were showered upon him; among others he was made field-marshal of the armies of France, Russia, Austria and Prussia.

With the return of peace he resumed the career of politics. He accepted the post of Master-General of the Ordnance with a seat in the Cabinet of Lord Liverpool in January 1819. In 1822 he represented Great Britain in the Congress of Vienna. In 1826 he was appointed high-constable of the Tower and went to Saint Petersburgh as Ambassador on the affairs of Greece. On 22 Jan. 1827 he succeeded the Duke of York as commander-in-chief of the forces. On the accession of Canning to office (April 1828) he set the bad example of resigning this post on political grounds. He resumed it again on the accession of Lord Goderich. On 8 Jan. 1828 he accepted the premiership and, resigning the command of the forces, gave it to Lord Hill. During his first year of office he carried the repeal of the Test and Corporation Acts. In January 1829 he was appointed governor of Dover Castle and lord warden of the Cinque Ports. This year he carried the Catholic Emancipation Bill. Both this and the repeal of tests were reforms which he had steadfastly opposed and which he yielded to necessity rather than conviction. He fought a duel in defense of his conduct on this bill with Lord Winchilsea on 21 March. In 1830 repeated motions for parliamentary reform were defeated, but the growing discontent throughout the country on this subject and a defeat in Parliament caused the resignation of the government in November. His opposition to reform made the duke so unpopular that he was assaulted by a mob on 18 June 1832 and his life endangered. He accepted the office of Foreign Secretary under Sir Robert Peel, 9 Dec. 1834, and retired with him, 8 April 1835. In the Peel ministry in 1841 he took a seat in the Cabinet without office. On 10 Dec. 1842, on the death of Lord Hill, he resumed the

command of the forces, which he held until his death. On the return of Peel to office in 1846 he supported him in carrying the repeal of the corn-laws, which up until then he had opposed. From this time his general policy in Parliament was to support the government of the day.

WELLINGTON, wĕl'ĭng-tŭn, municipality, Australia, in New South Wales, situated 160 miles northwest of Sydney. It is a gold-mining center; also known for its dairy products, wool, and wheat. Pop. (1947 est.) 4,723.

WELLINGTON, urban district, England, in Shropshire, situated 10 miles east of Shrewsbury. It is in a coal-mining region; its manufactures are machinery, agricultural implements, toys and flour. Nearby is The Wrekin, an isolated volcanic hill, 1,335 feet. Pop. (1951) 11,412.

WELLINGTON, urban district, England, in Somersetshire, situated six miles west-southwest of Taunton. It is a market for agricultural products and has woolen mills; asbestos and bricks also are manufactured here. Notable is its 15th century church. Nearby is a monument to the duke of Wellington who took his title from the town. Pop. (1951) 7,132.

WELLINGTON, town, India, in Nilgiri district, southwest Madras. Formerly known as Jakatala, it is a suburb of Coonoor, a military convalescent station. Its manufactures are cordite and chemicals. It is also the site of an army college. Pop. (1951) 8,372.

WELLINGTON, city, Kansas, and seat of Sumner County, altitude 1,189 feet, is served by the Atchison, Topeka and Santa Fe, and the Chicago, Rock Island and Pacific railroads. It is located 27 miles south of Wichita, and is a railroad center with railroad repair shops. Situated in an agricultural region, it is a trade center for grain and other agricultural products, and also has grain elevators, flour mills and some manufactories. It is the seat of the Sumner County High School. Situated at a point where Chisholm Trail travelers paused to rest their teams, Wellington grew as a trading center and gained impetus with the discovery of oil in the vicinity in the 1930's. It was laid out in 1871 and incorporated in 1872. The city government is by a mayor and council. Pop. (1950) 7,747.

WELLINGTON, city and seaport, New Zealand, seat of Hutt and Makara counties, capital of Wellington provincial district, and capital city of New Zealand, altitude 10 feet, is situated on a mountainous site at the head of Wellington Harbor (formerly Port Nicholson). It is at the geographical center of the Dominion, on Cook Strait which separates the North and the South Islands. It is the southernmost railroad terminal on the North Island, and has an airport with modern transoceanic and internal service. The fine harbor, three miles wide at its mouth, and 12 miles long, has wharfage facilities, served by hydraulic machinery and railways, for ocean-going vessels. The city is situated 1,200 miles southeast of Sydney, Australia.

Industries and Manufactures.—Chief among its manufactures are woolens, rope, packed meats, matches, soap, and brick. Building stone and fish are produced, and an extensive export trade is carried on in wool, meat, hides, skins, butter, cheese, and hemp.

Principal Buildings.—The modern eight-story building which houses government departments contrasts strikingly with the old government building constructed entirely of wood in 1876 which is still in use. The parliament buildings include the Parliament House and the General Assembly Library. The fine townhall, the supreme court building, and the fine railroad terminal also are noteworthy.

Educational and Cultural Facilities.—The University of New Zealand, Victoria University College, and St. Patrick's College have faculties of arts, commerce, science and law; the Dominion Museum has rare biological collections, New Zealand antiquities, and examples of native Maori carvings; the National Art Gallery conducts a school of art and has valuable exhibits of paintings and sculpture; the public library, a fine modern institution, also has a lecture hall and music rooms; and the Alexander Turnbull Library has many rare manuscripts and books. The War Memorial of sculptured marble is the scene of annual Anzac Day commemorations. The Botanical Gardens and public parks, on elevated sites, command a splendid view of the city and port. Popular lectures on astronomical science are conducted from the Carter Observatory and the meteorological and seismological station.

Recreational Facilities.—The city has many reserves, golf clubs, and play centers for bowling, tennis, basketball and- football; also seashore facilities for boating and yachting, surfing, fishing and swimming. The scenic beauty of the harbor is particularly noteworthy.

History and Government.—The settlement of Britannia was established at Petone in 1840 by 2,000 emigrants from the United Kingdom. Out of this arose Wellington in the development of which city more than 300 acres have been reclaimed from the sea. The seat of the Dominion government, originally in Auckland, was transferred here in 1865. The city is an independent unit under a municipal government. Pop. (1945) 123,771; (1951) 133,400.

WELLINGTON, provincial district, New Zealand, one of the nine provincial districts of the dominion of New Zealand, is the southernmost of the four districts of the North Island; its area is 10,870 square miles. Parallel to the mountain range which extends through most of its length, and nearer the coast, is a series of lower ranges. Between these two mountain systems extends the Waiarapa Plain, merging northward into an undulating country. A considerable extent of fairly level country is also found along the west coast. The district is well watered by several

rivers and in the south are Lakes Waiarapa and Onoke. In the north is the Tongariro National Park, an area of 235 square miles which includes three intermittently active volcanoes: Tongariro (6,458 feet), Ruapehu (9,175 feet), and Ngauruhoe (7,515 feet).

The district is well wooded, and exports timber. Much of the surface is primarily sheep-grazing land and, in addition, cattle and horses. The main crops are grain, potatoes, and turnips. Little mineral wealth has been found in the district, but some gold has been worked. Railroads run from the capital city of Wellington to Napier and Auckland. Pop. (1945) 349,404.

WELLINGTON, village, Ohio, in Lorain County, altitude 856 feet, served by the New York Central, and the Wheeling and Lake Erie railroads, is 14 miles south of Elyria. It is located in a dairying and grain area; its manufactures are: castings, trucks, steel products, glass cloth, and livestock medicines. There is a public library. Archibald M. Willard, painter of *The Spirit of '76,* is buried here. Settled in 1818, incorporated in 1855, the village has a mayor and council form of government. Pop. (1950) 2,992.

WELLMAN, wĕl'măn, **Walter,** American journalist and explorer: b. Mentor, Ohio, Nov. 3, 1858; d. New York, Jan. 31, 1934. He was the founder of the Cincinnati *Post* (1879) and from 1884 to 1911 he was Washington correspondent of the Chicago *Herald* and *Record-Herald.* In 1892 he located the landing place of Columbus in the New World, on Watling Island (San Salvador) in the Bahamas, and built a monument on the spot as he had determined it. In 1894 he led an expedition to Spitzbergen, and in 1898–1899 to Franz-Josef Land.

WELLS, Carolyn, American writer: b. Rahway, N. J.; d. New York, N. Y., March 26, 1942. Miss Wells was the author of over 170 books, 70 of which were mystery stories. Most of her early writing was in the field of children's literature. The *Story of Betty* was the first of these to have wide success. In 1902 she published her first anthology—*A Nonsense Anthology*—which was enthusiastically received by humorous writers of the period. This was followed by *A Satire Anthology* (1905); *A Whimsey Anthology* (1906); *The Book of Humorous Verse* (1920); and the *Book of Limericks* (1925).

Miss Wells had little interest in the mystery story until 1910 but from then on the "puzzle story" captured her imagination. Many of her books in this field were noted for wit and cleverness of plot. She created the detective character Fleming Stone and in 1933 the *Fleming Stone Omnibus* was published. In 1929 she wrote a critical study—*The Technique of the Mystery Story* which writers in the field considered the most understanding study published up to that time. Her autobiography *My Life* was published in 1937.

WELLS, Charles Jeremiah (pseudonym H. L. Howard), English poet: b. probably London, Eng., about 1799; d. Marseilles, France, Feb. 17, 1879. He was a friend of William Hazlitt, noted essayist, and of John Keats, poet. His outstanding work was the pseudo-Jacobean drama in verse, *Joseph and His Brethren* (1824) which won the praise of Dante Gabriel Rossetti, and was reviewed by Swinburne. Reprinted in 1876, it brought a considerable meed of praise to the author in his last years.

WELLS, David Ames, American political economist: b. Springfield, Mass., June 17, 1828; d. Norwich, Conn., Nov. 5, 1898. He was graduated from Williams College in 1847. In 1848, on the staff of the *Springfield Republican,* he invented a folding device to be attached to printing presses. In 1851 he graduated from the Lawrence Scientific School at Cambridge, where he was a special pupil of Louis Agassiz, and appointed assistant professor. While there he collaborated with George Bliss (1850) in the publication of *The Annual of Scientific Discovery* which he continued until 1866. In 1856 he made some improvements in the manufacture of textiles.

In 1864 Wells attained distinction as a political economist by the issuance of a pamphlet entitled *Our Burden and Our Strength* of which 200,000 copies were distributed. It discussed the resources of the United States in regard to the nation's debt-paying ability. It was translated into German, French, Dutch and other languages and helped in restoring domestic and foreign confidence in greenbacks and bonds which had fallen to one half their face value. It attracted the attention of President Lincoln and brought to Wells the appointment as chairman of the national revenue commission. In 1866 he was made special commissioner of revenue and the bureau of statistics was established. *The Reports of the Special Commissioner of the Revenue,* 1866–1869, recommended the use of stamps in the collection of revenue on liquor and tobacco. In 1870 the office was abolished. Wells at first was an advocate of the protectionist policy, but after a visit to Europe and a study of the English system he changed his views and became an advocate of free trade, and the abolition of the tariff. Later, he was counsellor on tariff matters to presidents Garfield and Cleveland.

In 1870 Wells was appointed chairman of the New York State Tax Commission, and in 1878 he became a member of the board of arbitration of the Associated Railways. He took an active interest in politics; was several times a delegate to Democratic national conventions. He was also an unsuccessful candidate for Congress to represent Connecticut in 1876 and 1890. His chief interests were tariff questions, the theory of money, the currency question, and taxation. He was an effective writer against fiat money or depreciated monetary standards; in 1896 a stanch opponent of "free silver" advocated by William Jennings Bryan; and an opponent of income taxes. Always an advocate of the policy of *laissez faire,* he was adept in the adaptation of statistics to popular fancy. Throughout his life Wells was a versatile and effective writer.

In 1857–1858, while a partner in the publishing business, he compiled: *The Science of Common Things* (1857); *Wells's Principles and Applications of Chemistry* (1858); and, later, *Wells's First Principles of Geology* (1861); and *Wells's Natural Philosophy* (1863) which went through 15 editions. Among his many other writings are: *The Relation of the Government to the Telegraph* (1873); *The Silver Question* (1877); *Why We Trade and How We Trade* (1878); *Our Merchant Marine* (1882); *A Primer of Tariff Reform* (1884); *Practical Economics*

(1885); *The Theory and Practice of Taxation* (1900).

WELLS, Frederic Lyman, American psychologist: b. Boston, Mass., April 22, 1884. After taking his Ph.D. at Columbia University in 1908, he was connected with the faculty there from 1905–1907 and again in 1910–1911. He was also assistant pathological psychologist at McLean Hospital, Waverly, Mass., 1907–1910, 1918–1921. From 1921–1928 he was chief of the psychological laboratory of Boston Psychopathic Hospital and in 1931 joined the faculty of Harvard Medical School, first as instructor, then as medical adviser to the hygiene department, and from 1938 until his retirement in 1950 he was psychologist of the school. During 1941–1946 he was consultant in the Office of the Adjutant General of the United States War Department. He has carried on special research in the mental measurements of superior adults.

He is the author of *Mental Adjustments* (1917); *Pleasure and Behavior* (1924); *Mental Tests in Clinical Practice* (1927); *Mental Examiners' Handbook* (1945).

WELLS, Herbert George, English novelist, sociological writer, and historian: b. Bromley, Kent, Sept. 21, 1866; d. London, Aug. 13, 1946. Born of a lower middle class family, he was apprenticed to a draper at the age of 13. Three years later, by educating himself, he was able to become an assistant master at Midhurst Grammar School. With the aid of a government scholarship, he attended the Royal College of Science, where he studied with Thomas Henry Huxley, taking his B.Sc. degree in zoology from London University in 1888, and his doctorate in 1944. For a time he worked as a private tutor in science, but in 1893 definitely turned to journalism, and in 1895 his first book, *Select Conversations with an Uncle,* was published.

An idealist and social reformer, Wells was constantly preoccupied with the problem of how to create a better society, a world order of peace and progress under the guidance of the highest intelligence. His persuasive criticism of existing social problems and his suggestive perceptions of the possibilities of various social and scientific developments exercised a widespread influence upon his generation.

Wells' fiction may be divided into three categories: fantastic scientific romances, often with overtones of social prophecy—*The Time Machine* (1895); *The Island of Dr. Moreau* (1896); *The Invisible Man* (1897); *The War of the Worlds* (1898); *The First Men in the Moon* (1901); *The Food of the Gods* (1904); *In the Days of the Comet* (1906); *The War in the Air* (1908); *The World Set Free* (1914); realistic, often humorous and satirical, novels of character and contemporary life—*Love and Mr. Lewisham* (1900); *Kipps* (1905); *Tono Bungay* and *Ann Veronica* (1909); *The History of Mr. Polly* (1910); *Mr. Britling Sees It Through* (1916); *Christina Alberta's Father* (1925); *The Bulpington of Blup* (1933); and ideological novels, which serve mainly as vehicles for his social and political theories—*The Research Magnificent* (1915); *Joan and Peter* (1918); *Men Like Gods* (1923); *The World of William Clissold* (1926); *Meanwhile* (1927); *Mr. Blettsworthy on Rampole Island* (1928); *The Shape of Things to Come* (1933). From a literary point of view, the novels written before 1920, with their wit, invention, and vitality, are by far the most satisfactory; his later fiction became increasingly discursive and didactic. His most important work of nonfiction is *The Outline of History* (1920), which together with *The Science of Life* (in collaboration with Julian Huxley and G. P. Wells, 1929) and *The Work, Wealth and Happiness of Mankind* (1932) forms a trilogy which considers mankind historically, biologically, and economically.

Other works of nonfiction include: *Anticipations* (1901); *Mankind in the Making* (1903); *A Modern Utopia* (1905); *The Misery of Boots* (1907); *New Worlds for Old* and *First and Last Things* (1908); *An Englishman Looks at the World* (1914); *Russia in the Shadows* (1920); *The Salvaging of Civilization* (1921); *A Short History of the World* (1922); *The Book of Catherine Wells* and *The Open Conspiracy* (1928); *Experiment in Autobiography* (1934); *World Brain* (1938); *The Fate of Man* (1939); *The New World Order* (1940); *Guide to the New World* (1941); *'42 to '44* (1944); and *Mind at the End of its Tether* (1945). From his youth a Socialist, Wells joined the Fabian Society in 1903, but had broken with the group by 1906.

WELLS, Horace, American dentist: b. Hartford, Vt., Jan. 21, 1815; d. New York, New York, Jan. 24, 1848. He studied dentistry in Boston, and practiced there until 1836, when he went to Hartford, Conn. From 1840 he was interested in the anesthetic effects of nitrous oxide, commonly known as laughing gas. Gardner Q. Colton's demonstrations of the effects of nitrous oxide inspired him to use it in a dental case before the Harvard medical class (1845), but the result, because the patient was not completely anesthetized, was unsatisfactory. He nevertheless used nitrous oxide gas in his practice.

Wells' claims to priority in the discovery of anesthesia were controverted in the interest of G.Q. Colton, Charles T. Jackson, William T. Morgan, J. C. Warren, and C. W. Long (qq.v.) each of whom shared in the honors of its discovery, regarding which priority remains a moot question. Wells became mentally unbalanced while advocating his claims in New York, and committed suicide. A statue stands to his memory in Bushnell Park, Hartford, Conn. He published *A History of the Application of Nitrous Oxide Gas, Ether and Other Vapors to Surgical Operations* (1947). See also ANAESTHETICS.

WELLS, Horace Lemuel, American chemist: b. New Britain, Conn., Oct. 5, 1855; d. New Haven, Conn., Dec. 19, 1924. He was graduated from Yale in 1877, instructor there 1884–1888, assistant professor of chemistry 1888–1893, professor of analytical chemistry and metallurgy 1893–1923, and emeritus thereafter. He made numerous original investigations in inorganic chemistry, and was elected to the National Academy of Sciences in 1903. He was the author of *Studies from the Chemical Laboratory of the Sheffield Scientific School* (1901); *Chemical Calculations* (1903).

WELLS, Rolla, American capitalist: b. St. Louis, Mo., June 1, 1856; d. there, Nov. 30, 1944. He entered business in the employ of a street and railway company and became assistant superintendent and finally general manager. Giving up the latter position in 1883, he became iden-

tified with a number of manufacturing and commercial firms. A democrat in politics, Wells served as mayor of St. Louis two consecutive terms, 1901–1909. From 1919 to 1927 he was receiver for the United Railways Company of St. Louis.

WELLS, William Charles, British physician: b. Charleston, S. C., May 24, 1757; d. London, England, Sept. 18, 1817. The son of a Scottish printer who settled in South Carolina in 1753, he was graduated an M.D. at the Edinburgh University in 1780. A year later he returned to America and after 1782 he published for a time a weekly newspaper in St. Augustine, Fla. In 1784 he settled in London to practice medicine and from 1800 until his death he was chief physician at St. Thomas' Hospital. Wells was elected a Fellow of the Royal Society in 1793 and in 1814 received the society's Rumford Medal for his *Essay on Dew* (1814), the first exact explanation of the phenomenon. He wrote several medical papers, among them *On Vision* (1811). A selection from his papers and his autobiography were published in 1818.

WELLS, municipal borough of England, in Somersetshire, at the foot of Mendip Hills, 17 miles south of Bristol. The name is derived from St. Andrew's Well, thought in the Middle Ages to possess curative value. A Roman settlement, Wells was an important town of Wessex in Saxon times. In 909 it became the seat of a bishop, later transferred to Bath. Bishop Jocelin returned to Wells and after 1246 the bishop took the title of bishop of Bath and Wells. The cathedral, though comparatively small, is one of the finest in England. It is Early English and the west front, adorned with over 300 sculptured figures, is one of the finest examples of the style. Started in 1186, the church was mostly built in the 12th and 13th centuries; the central tower, 182 feet high, the chapter house in Decorated style, and the fine lady chapel are 14th-century additions. Beautiful examples of the 15th-century woodwork are the oak stalls and bishop's throne. The cathedral, the moated 13th-century bishop's palace, the deanery, the Vicar's Close consisting of two rows of medieval houses for the clergy, are all enclosed by medieval walls. A theological college is located in Wells. In the subterranean caves of Wookey Hole near Wells prehistoric remains were found. Pop. (1951) 5,835.

WELLS, town, Maine, in York county, on the coast 27 miles south-southwest of Portland. It lies in an agricultural area and includes the beach resorts of Wells Beach and Ogunquit, the latter a headquarters of a summer theater group. The town was founded about 1640 and was incorporated in 1653. Pop. (1950) 2,321.

WELLS, town, Nevada, in Elko County, 45 miles northeast of Elko, at an altitude of 5,626 feet, on the Southern Pacific and Western Pacific railroads and the southern terminus of the Union Pacific. It has an airport and lies on the transcontinental highways U.S. 40 and 93. There are limestone quarries. Wells, a supply center for the cattlemen of the upper Humboldt River Valley, was settled in 1870 and incorporated in 1927. West of Wells is the East Humboldt Range, now part of the Humboldt National Forest. Pop. (1950) 947.

WELLS COLLEGE, a private college of arts and sciences for women in Aurora, N. Y.; the 300-acre campus is located on Cayuga Lake, in the heart of the Finger Lakes District. It is undenominational and accredited by the Association of American Universities and by the Middle States Association of Colleges and Secondary Schools. The college was founded in 1868 by Henry Wells, who at that time deeded to the trustees the main building and 20 acres of land; it was chartered as Wells College for the Higher Education of Young Women, and took the present name in 1870. In 1888 the main building was destroyed by fire, but immediately rebuilt. A preparatory course, maintained at first, was abolished in 1896, when the range of elective system was also greatly increased. The A.B. and B.S. degrees are now conferred for the completion of the course, which is largely elective, specially in the last two years. The student enrollment averages 305 a year; the faculty numbers about 45; and the library contains about 110,000 volumes. The college buildings include the main hall, Morgan Hall, a dormitory, a gymnasium, a science hall, and the administration building; the College Boat Club has erected a boathouse for its members.

WELLS AND WELL-SINKING. Wells are excavations for water or other substances such as petroleum, gas, or salt; well-sinking is, therefore, the operation by which deep holes of comparatively small diameter are sunk into the earth. Similar holes are drilled in search of coal, iron ore, and other minerals; although in this case water is not the object in view, work of this character may properly be regarded as well-sinking. The process of well-sinking usually implies also the casing of the well either to guard against the choking of the well or to shut out liquids from all strata except that which the well is designed to tap. Wells are variously classified according to the method of sinking, a dug, bored, driven, drilled and jetted; a curb, case or tube wells according to the manner of lining them; as open, shallow or deep; and as artesian, flowing, non-flowing and pumping.

As regards the dug well, the method employed is to excavate it with pick, shovel, or drill shoring the sides with stout planking as the excavation proceeds.

Boring or drilling, however, differs essentially from digging in that all the operations are conducted from the surface, the hole being from 3 to 27 inches or more in diameter. Two distinct methods of well-sinking are commonly included under the terms well-drilling and well-boring by which a hole is made, viz., the grinding with a rotating motion, and the pounding or shattering of rocks with a churning motion. The two methods are represented on the one hand by the diamond drill and the rotary outfit, and on the other by the rope drill or cable tool outfit; the last two are seen in their highest development in the drilling of wells for oil and gas. The first cuts or bores a hole, either cylindrical or annual, at any desired inclination, and works under pressure, while the other two, depending on sheer weight, sink a vertical hole. The diamond drill may be used for testing formations, and finds its greatest utility in exploring the harder inclined rocks for deposits of coal, iron and copper ore, the precious metals, etc. There are variations of the diamond drill used in vertical exploration for the pur-

pose of obtaining a sample or core of the rock encountered. For drilling to shallow depths and up to 1,000-2,000 feet, with the object of securing a hole through which water or other liquids may be lifted, the common apparatus used is the drilling machine, which is a portable outfit of the rope or churn drill class. The method of operation is similar to that of the heavier drilling apparatus or string. The Standard rig for rope tools consists principally of a derrick, belt house and engine house. The derrick, which is the prominent feature of an oil field landscape is a skeleton framework from 72 to 110 feet in height. The actual drilling tools consist of a connected series of solid steel bars, the main unit of which is the stem. The stem, a long round bar fitted with a milled pin at the upper end and a complementary box at the other, is usually 40 to 60 feet in length, and 4 to 6 inches in diameter; it serves the double purpose of aligning the hole and giving weight to the blow of the bit. The bit by means of its pin is screwed into the box of the stem. At the lower end of the bit is the cutting or hammering edge dressed out to the size of the hole to be carried down. Bits themselves have considerable weight, in some cases approaching a ton. Above the stem for ordinary drilling the rope socket is attached and is itself suspended from the rope used for lowering and raising the drilling tools and constituting the drilling rope. At some stages of the drilling it may be necessary to add to the tools a set of jars, and they are placed between the stem and rope socket. The jars like two links of a chain afford some play, so that a quick lift of the rope will impart a jerk to a bit which may have become stuck in a tight formation, and ward off the necessity of fishing for tools.

The first stage in cable tool drilling is that of spudding. When the drilling tools are in position above the opening in the derrick floor, it is seen that the rope suspending them runs over a pulley, called the crown pulley, which is set in the crown block on top of the derrick, and that the rope at its free end is wound on the shaft of the bull wheels at the back side of the derrick. The spudding outfit is a jerk line connection between the drilling rope near the bull wheels and crank of the power connection. By this arrangement a pull is exerted on the drilling rope lifting the tools, followed by a slackening which permits them to fall and begin the work of making the hole. By releasing the bull wheel brakes momentarily the driller is able to let out rope as required. There is some elasticity or spring to a manila rope or cable in contrast with the stiffness of a steel wire rope or line that makes the former especially desirable for shallow drilling. As soon as the surface soil and water are gone through, a piece of pipe or casing of ample diameter is set in the hole making a seal and thereby keeping the hole dry. However, in drilling, a quantity of water is run into the hole in order that the cuttings or drillings may be mixed into a mud which can be removed from time to time by means of the bailer. The bailer is a tube ordinarily about 20 feet long which can be let into the hole by means of a wire rope called the sand line; at its upper end is the bale for attaching the line, and at the lower end a valve with a dart. The projecting dart strikes bottom and lifts the valve for the inrush of mudded water, and as the bailer begins to ascend, drops the valve into place. The sand line runs from the derrick top to the sand reel beyond the derrick floor. All power used in handling tools is derived through the medium of the band wheel, which is set about midway between the derrick and the engine in the belt house. Power from the engine pulley is transmitted by means of a belt to the band wheel which revolves on the crank shaft. The sand reel operates through a friction pulley coming into contact with the face of the band wheel. On the side of the band wheel opposite the crank is fitted a tug pulley from which the bull ropes extend into the derrick and, when in use, operate the bull wheels in order to bring the drilling tools out of the hole. The entire drilling apparatus with its belting, ropes, and general construction of wood, can be viewed as adapted to an elastic transmission of power. Of this nature is the great mounted wooden timber which forms the walking beam and comes into use as soon as the spudding operation is finished. At its outer end the walking beam is connected with the crank by means of a pitman; inside the derrick it makes connection with the drilling rope by means of a temper screw and clamps. While the clamps hold the rope, the temper screw, which is essentially a screw five to six feet long supported in a threaded box, can be let out as the hole is deepened.

When a water bearing formation is encountered in drilling for oil and the quantity of water interferes with drilling, it is customary to seal off this formation by setting pipe, called casing, in the hole. Casing is made of steel or iron usually in joints of about 20 feet in length, and about 4 inches to 16 inches in diameter. The joints are screwed together as they are lowered into the hole. For handling casing there are special pulleys and wire lines. In California where casing followed the tools closely on account of caving formations, it was customary before the rotary method became general to use a separate wheel with shaft, called the calf wheel, for operating the casing lines. Drilling was then largely a process of under-reaming, by which a special bit, called the under-reamer, expanded below the casing and enlarged the hole sufficiently to lower it. After a string of casing is set, drilling is resumed through it in a contracted hole. A string of casing is generally set just before penetrating the formation from which production is expected. If there is no suitable cap rock for insuring a perfect seal, cement is used. At this point when the rotary method of drilling has been used, a change is often made to the cable tool method, in order to avoid mudding the formation containing the oil and gas. In some localities gas pressure makes drilling impossible; the well may be allowed either to drill itself in or blow off until the pressure is reduced sufficiently. After drilling is finished, the well is tubed by means of pipe usually of two to four inches diameter; and when it ceases to flow it is operated with pumping equipment, artificial pressure, or other means.

The cable tool method has in many fields been replaced by the rotary method, which at first was adapted only to the softer formations. This objection was largely overcome by using heavier material and special cutting devices Great advantages are that it seals the formations as they are met, and thereby dispenses with considerable casing and the time and cost of

handling it. The rotary outfit consists mainly of a string of pipe rotated by means of a table on the floor of the derrick; power is transmitted to the table by means of a chain or shaft drive from the engine. The pipe is raised and lowered by means of the draw works which take the place of bull wheels. On the derrick floor is a set of pumps, which force a fine mud mixture down through the rotary pipe and up along the walls of the hole, effectually plastering them. By means of sump holes near the pumps the cuttings which are carried up in the mixture can settle out, and the consistency of the mud be regulated. The pumps work under pressures of as many hundreds of pounds as necessary to secure circulation and seal gas formations. There are water holes through the bit attached to the bottom of the lowest joint of pipe. Ordinarily the bit is one called the fishtail on account of its shape. When it becomes necessary to change bits or for any other reason to remove the pipe from the hole, the pipe is set in stands on the derrick floor. To allow for this, the rotary derrick is made 120-200 feet in height. The rotary method is generally used in the Mid-Continent, Gulf Coast and California fields, as well as abroad, for deep well drilling. In some countries, as Canada and Galicia, a string of rods took the place of the cable. Wells have also been secured by driving pipe or points to shallow depths. The deepest well in the world in 1925 fell short of 8,000 feet. Now there are wells which have passed 15,000 feet in drilling depth, and there is a constant effort to improve machinery, tools and technique, in order that lower productive horizons may be penetrated. See also ARTESIAN WELLS; PETROLEUM.

WELLSBORO, borough, Pennsylvania, Tioga County seat; altitude 1,311 feet; 38 miles north-northwest of Williamsport; on the New York Central Railroad. In addition to the products of the surrounding region of farms, timber, natural gas wells, and coal mines, it produces lightbulbs and evaporated milk. Nearby Pine Creek Gorge is a tourist attraction. Settled in 1799 and incorporated in 1830, Wellsboro is governed by a burgess and council. Pop. (1950) 4,215.

WELLSBURG, city, West Virginia, Brooke County seat; altitude 635 feet; 16 miles north-northeast of Wheeling; on the Ohio River, and the Pennsylvania, and the Pittsburgh and West Virginia railroads. It is in the coal region of the northern panhandle of the state; sheep, cattle, and apples are raised in the surrounding area. Its industries include oil cans, cement and flour bags, paper bags, and glassware. Wellsburg was founded in 1790, and is governed by a mayor and council. Pop. (1950) 5,787.

WELLSTON, town, Missouri, in St. Louis County and a suburb of St. Louis. A business and manufacturing center, Wellston was incorporated in 1949 and is governed by a mayor and council. Pop. (1950) 9,396.

WELLSTON, city, Ohio, in Jackson County; altitude 700 feet; 26 miles east-southeast of Chillicothe; on the Baltimore and Ohio, and the Chesapeake and Ohio railroads. In a region of iron, coal, limestone, and clay, it was formerly a coal mining and smelting center, but the manufacture of machinery, tools, clothing, and store fixtures is now more important. The site was first settled in 1871; the town is named after Harvey Wells who set up a blast furnace here in 1874. Incorporated in 1876, it is governed by a mayor and council. Pop. (1950) 5,691.

WELLSVILLE, village, New York, in Allegany County; altitude 1,517 feet; 20 miles southwest of Hornell; on the Genesee River, and the Erie, and Baltimore and Ohio railroads. A summer resort in an agricultural and dairying area, it is also a refining center for the Allegany County oil field. It manufactures oil and gas well supplies, turbines, and aircraft parts. Named after Gardiner Wells, one of the original settlers in 1795, it was incorporated in 1871 and is governed by a mayor and council. Pop. (1950) 6,402

WELLSVILLE, city, Ohio, in Columbiana County; altitude 708 feet; 16 miles north of Steubenville, on the Ohio River and the Pennsylvania Railroad. It is in a farming, dairying, fruit growing, and coal mining region. Valuable clay deposits in the vicinity make possible the manufacture of pottery, chinaware, and bricks, the city's chief industries. There are also machine and railroad shops. William Wells and others from Washington County, Pennsylvania, first settled here in 1797. Chartered in 1890, the city is governed by a mayor and council. Pop. (1950) 7,854.

WELSBACH LIGHT. See GAS ILLUMINATION, HISTORY OF.

WELSER, vĕl'zĕr, **Bartholomäus,** German merchant prince: b. Augsburg, 1488; d. Amberg, Swabia, 1561. Son of an important merchant of Augsburg, on his father's death he and his brother Anton formed the commercial and banking firm of Welser and Company. Their business prospered and they became bankers to the emperor Charles V, to whom they made large loans. In return, Bartholomäus was made a nobleman of the empire, given a general safe conduct and the privilege of exemption from some local courts. Finally, unable to repay his debts, Charles granted the firm (1528) exclusive rights to the exploitation of the Spanish colony of Venezuela. The Welsers monopolized the import and export trade and attempted to colonize the country. Disputes with the Spanish government, however, prevented the undertaking from proving profitable, and a legal decision in 1546 returned the colony to the Spanish crown. Bartholomäus retired from business in 1553.

WELSH, Herbert, American reformer: b. Philadelphia, Pa., Dec. 4, 1851; d. Montpelier, Vt., June 28, 1941. He was graduated from the University of Pennsylvania in 1871; studied art in Philadelphia and with Bonnat in Paris; and practiced as an artist in Philadelphia for several years. A visit to the Sioux reservation led him to begin a movement which resulted in the organization of the Indian Rights Association to secure just and consistent treatment of the Indians by the government. He was corresponding secretary for 34 years and for 11 years president of this association, which was instrumental in securing the passage of a bill providing for the individual ownership of land by Indians and for the

extension of the civil service law to the Indian service.

As an advocate of good government, he played a leading part in the revolt against "boss rule" in Pennsylvania which secured the election of Robert E. Pattison (q.v.) as governor in 1890. He lectured and wrote on municipal government and civil service reform, and in 1895 established *City and State,* a weekly periodical, which he edited until 1904. He was a champion of international arbitration, and strongly opposed the forceful acquisition of the Philippines, helping to expose the behavior of the army there.

He wrote *Four Weeks among Some of the Sioux Tribes, Civilization among the Sioux Indians, A Visit to the Navajo, Pueblo, and Hualapai Indians, The Other Man's Country,* and *The New Gentleman of the Road.*

WELSH, John, American merchant: b. Philadelphia, Nov. 9, 1805; d. there, April 10, 1886. He was educated in his native city, where he became prominent in business and was active in public affairs in many capacities, having large railroad and financial interests. He was a member of the sinking fund commission, president of the Philadelphia Board of Trade, etc., and rendered efficient service in promoting relief measures during the Civil War, especially in connection with the Philadelphia Sanitary Fair, in 1864, of which he was president, and which raised over $1,000,000 for army hospital work. In 1873 he became president of the board of finance of the Centennial Exhibition, receiving from the citizens of Philadelphia, at its close, a gold medal and the sum of $50,000, with which he endowed the John Welsh chair of history and English literature in the University of Pennsylvania. In 1878 he went as minister to England, but in the following year resigned.

WELSH, Robert E., Scottish clergyman and educator: b. New Cumnock, Mar. 20, 1857; d. Ayr, Scotland, Sept. 1, 1935. Educated at Glasgow and Edinburgh universities, he was ordained to the Presbyterian ministry in 1880. He was minister of churches in Yorkshire, London, and Hove. General secretary of the Canadian Bible Society (1905–1907), he was for many years thereafter professor of the history and philosophy of religion at McGill United Theological College, Montreal. His books include *Man to Man* (1905) and *Classics of the Soul's Quest* (1922).

WELSH CALVINISTIC METHODISTS, a designation sometimes given to the Calvinistic Methodists, because Wales is the great seat of the sect. The Calvinistic Methodists are distinguished by their Calvinistic sentiments from the ordinary Wesleyans, who are Arminian. Whitfield is regarded as the father and founder of Calvinistic Methodism. Members of this sect have been active in seeking to bring about the disestablishment of the Anglican Church in Wales. See also Presbyterian Church in the United States of America.—*The Welsh Calvinistic Methodist.*

WELSH LANGUAGE AND LITERATURE. See Celtic Languages.

WELWITSCHIA, wĕl-wĭch'ĭ-ȧ, a genus of plants of the family Gnetaceae, containing only one species, *W. mirabilis.* This species is confined to the deserts of Southwest Africa, where it was discovered in 1860 by Friedrich Welwitsch. It has a short and top-shaped stem which never grows much above the surface, but increases in thickness until it may be three feet in diameter, and bears a pair of large opposite leaves. These leaves last throughout the whole lifetime of the plant and become ultimately torn up longitudinally into long strips, which trail on the surface of the ground. Two cotyledons which are like short-lived leaves of much smaller size precede them. The flowers of the plant grow in cones like those of many conifers, the cones being arranged in panicles on the end of the stem between the two leaves. The female cones are much larger than the male ones and in fruit are of a scarlet color.

WEMYSS - CHARTERIS - DOUGLAS, Francis, 10th Earl of Wemyss: b. Edinburgh, Scotland, Aug. 4, 1818; d. London, England, June 30, 1914. Educated at Edinburgh Academy and Christ Church, Oxford, he became (1841–1846) member of Parliament for East Gloucestershire, then (1847–1883) member for Haddingtonshire. He was a lord of the Treasury 1852–1855. Thereafter, styling himself a liberal-conservative, he acted independently in the Commons, opposing the growth of state interference but championing a number of reform measures. An organizer of the volunteer movement of 1859, he was a vocal advocate and critic of military reforms until his death. He was made an aide-de-camp to Queen Victoria in 1881, and entered the House of Lords in 1883.

WEN, an encysted tumor, or sebaceous cyst varying in size, occurring in different parts of the body, but mostly on the scalp and neck; commonly situated immediately under the skin. The causes of their formation are not understood, but a strongly marked tendency to such swellings exists in particular individuals, leading to the belief in constitutional causes. At its commencement the wen is indolent, and it is often many years before it attains any considerable size. It is enclosed in a sac, its contents being sometimes sebaceous matter, in other cases serum, or a thin fetid brown or black fluid. Sometimes the sac contains cartilaginous or even osseous matter. Frequently the sac, especially when small, may be punctured, and its contents pressed out; but sometimes this gives rise to very severe inflammatory action. Another and safe mode of treatment is to dissect them out with the knife wherever their position will admit of it, care being taken to remove the whole of the cyst.

WENATCHEE, wĕ-năch'ē, city, Washington, Chelan County seat, is situated at the junction of the Columbia and Wenatchee rivers, 60 miles north-northeast of Yakima, at an altitude of 642 feet. It is served by the Great Northern Railroad and Northwest Airlines.

It is the site of Wenatchee Junior College, Chelan County Hospital, the Washington State College Fruit Tree Experiment Station, and the North Central Washington Museum. The region attracts many tourists; Wenatchee and Chelan National Forests are nearby.

Founded in 1888 and incorporated in 1900, the city has a commission form of government. Pop. (1950) 13,072.

WENATCHI. See Salishan Indians.

WENCESLAUS, wĕn'sĕs-lâs or -las, or **WENZEL,** emperor of Germany and king of Bohemia: b. 1361; d. Prague, Aug. 16, 1419. He was the son of Charles IV (q.v.), whom he succeeded in 1378. In 1394 the Bohemian nobility formed a conspiracy against him and held him prisoner at Prague, but later released him. Through the influence of the archbishop of Mainz, whose enmity he had aroused by demanding the resignation of the rival popes, Benedict XIII and Boniface IX, he was deposed by the Imperial electors, while the Elector Palatine Rupert was chosen to succeed him. In Bohemia he supported John Huss (q.v.) and the latter's party, and in 1409 compelled by a decree the departure of the Germans from the University of Prague. Shortly afterward he resigned the royal title. Consult Lindner, 'Geschichte des Deutschen Reiches unter König Wenzel' (1875–80).

WEND LANGUAGE. The language of the Wends is similar to the other branches of the northwestern stem of the Slavic languages, the Polish and the Bohemian. It is divided into the dialect of Lower Lusatia, which is but little developed, and that of Upper Lusatia. The latter is subdivided into the Evangelical dialect, near Bautzen; the Catholic dialect, near Kamenz, and in the northwest; and the northeastern dialect. The differences are mostly confined to shades of pronunciation. The stock of words in the present language of the Wends is largely mixed with German elements. Orthography has always been in a very unsettled condition. In their publications, the Wends have mostly made use of the German letters. There are eight vowels, *a, o, u, e, i,* all of which are pronounced as in German and Italian, *ó* (between *o* in *note* and *u* in *full*), *é* (like long English *e*), and *y* (approaching the German *ü*). There are 32 consonants. There is no article. Nouns ending in a consonant are mostly masculine, those in *a* and *i* feminine, and those in *o* and *e* neuter. There are seven declensions. The language has a dual number. There are seven cases. The adjectives end in *y, i* (masculine), *a* (feminine), *o* and *e* (neuter). The comparative is formed by the termination *isi,* and in order to form the superlative the syllable *naj* is placed before the comparative. The personal pronouns are irregular; the others are declined like adjectives. The verb has six tenses and five moods, besides a gerund; and three participles. Till about the middle of the 19th century Wendish literature consisted almost wholly of ecclesiastical and religious works, and works relating to the needs of peasant life, but there has since been a revival of national feeling, accompanied by a more extended literature. There are grammars of the Wendish language by Ticinus (Prague 1679); Matthäi (1721); Seiler (Bautzen 1830), and Jordan (Prague 1841)

WENDELL, Barrett, American educator and author: b. Boston, Mass., 23 Aug. 1855; d. 8 Feb. 1921. Graduated, Harvard 1877, studied, Harvard Law School, in 1880–88 was instructor in English at Harvard, in 1888–98 assistant professor, and in 1898 became professor. He was Clark lecturer at Trinity College, Cambridge, England, in 1902. Among his works are 'The Duchess Emilia' (1885); 'Rankell's Remains' (1897); 'English Composition' (1891); 'Cotton Mather' (1891); 'Stelligeri, and Other Essays Concerning America' (1893); 'William Shakespere' (1894); 'A Literary History of America' (1900; in the 'Library of Literary History), a scholarly work, though much criticized for its unjust attitude toward certain writers; and 'Raleigh in Guiana' (1902), an attempt at imitation of the Elizabethan drama; 'Liberty, Union and Democracy' (1906); 'The Mystery of Education' (1909).

WENDS, a former powerful Slavic tribe settled in Germany, now represented by the Slavic people of Upper and Lower Lusatia, who call themselves Serbs (*Serbjo*), whence the name Sorbs, often applied to them by German authorities. In the earliest historical times the Sorbs occupied the country from the Saale to the Bober, and from the latitude of Berlin south to the Erzgebirge; but the Wends are now confined to a small territory (about 1,270 square miles) in the upper Spree Valley, extending from south of Bautzen to north of Kottbus. The larger part of this Wendish region belongs to the Prussian provinces of Brandenburg and Silesia, the smaller southern part being included in the Free State of Saxony (circle of Bautzen). The Wends are completely surrounded by Germans, and being thus cut off from contact with the other Slavs, they are becoming slowly Germanized. Their language, known as Sorbian, falls into two dialects Upper and Lower Sorbian, which are spoken in the south and the north of the territory, respectively. (See WEND LANGUAGE). The total number of Wends is about 120 000, of whom about 50,000 live in Saxony and 70,000 in Prussia. About 12,000 are Roman Catholics, the remainder being chiefly Lutherans.

WENER, vā'nĕr, or **VENERN,** Sweden, the largest lake of the country, and after those of Ladoga and Onega the largest in Europe, situated centrally between the läns of Wermland, Dalsland and Wester Götland. It is 147 feet above sea-level, and of irregular shape. Its greatest length, northeast to southwest, is about 90 miles; and its breadth may average about 30 miles, though in its southern part, where two peninsulas stretch far into it from opposite directions, it is not more than 15 miles. This distance is still further narrowed by a group of small islands, and hence the part of the lake above these peninsulas is sometimes considered as Wener proper, while the part below is called Lake Dalbo. The area covered by both is about 3,000 square miles. By far the most important feeder is the Klar-elf, which pours in at its north end the accumulated water of a course of more than 250 miles. Its only proper outlet is at Wenersborg at its southwestern extremity, where its superfluous waters are received by the Göta-elf, flowing thence to the Cattegat. In summer steamers and other vessels ply regularly upon the lake; in winter it is frozen for several months, and crossed by sledges. It abounds with fish, particularly trout. The Göta Canal connects Lake Wener with Lake Wetter, and the Dalsland Canal connects it with Fredrikshald in Norway.

WENLEY, Robert Mark, American educator: b. Edinburgh, Scotland, July 1861. He

was graduated from the University of Glasgow in 1884, and later studied in Edinburgh and on the Continent. He was head of the philosophical department of Queen Margaret College, Glasgow, 1888–95 and thereafter head of the same department at the University of Michigan. Author of 'Socrates and Christ' (1889); 'Preparation for Christianity in the Ancient World' (1898); 'Kant and His Philosophical Revolution' (1910); 'The Anarchist Ideal' (1913); 'Robert Flint' (1914); 'G. S. Morris's Life and Work' (1917); 'Stoicism and Its Influence' (1924); 'Poetry of John Dryden' (1924). He was an associate editor of the 'Dictionary of Philosophy' and the 'Encyclopedia of Religion and Ethics.' Died, 29 Mar. 1929.

WENLOCK GROUP, a British formation of the Upper Silurian geological series. It includes shales and limestones, and is below the Ludlow group and above the Upper Llandovery group, these three comprising the Upper Silurian groups. The Wenlock formation is about 4,000 feet thick, and the fauna has been classed as consisting of 171 genera and 530 species, but many supposed vegetable remains are almost certainly not such. See SILURIAN.

WENSLEYDALE, wĕnz'lĭ-dāl, **James Parke,** BARON, English jurist: b. Highfield, near Liverpool, 22 March 1782; d. Ampthill Park, Bedfordshire, 25 Feb. 1868. Graduated from Trinity College, Cambridge, in 1803, he was called to the bar at the Inner Temple in 1813, went the northern circuit and became known for his wide knowledge of common law. In 1828 he was made a justice of the Court of King's Bench, in 1834 was transferred to the Court of the Exchequer. Here he remained strongly influential until his resignation in 1856, when he entered the Lords as Baron Wensleydale of Walton (Lancaster). In Parliament he spoke rarely, and chiefly on legal questions. His judgments were highly ranked. Consult Foss, 'The Judges of England' (1848–64), or the abridgment of the same, 'Biographia Juridica' (1870); Manson, 'Builders of Our Law' (1895).

WENTLETRAP, a gastropod mollusk, allied to the turret shells and of the genus *Scalaria,* in which the shell is turreted, spiral and ornamented with elevated rib-like processes, crossing the whorls lengthwise of the shell. In some species the spiral is closed; but in the "true" wentletraps the whorls are open, that is, separated. Of the former, some are found in northern seas, and the latter are all natives of warm seas. They are inhabitants of deep waters, but their shells are cast up in great numbers on sandy coasts. They are carnivorous in habits. The famous precious wentletrap, or royal staircase (*Scalaria pretiosa*), formerly brought prices ranging as high as $250 when purchased for the conchologist's cabinet, but its value in the present day is small. Its shell is about two inches long, and twisted in a wide spiral form, and is generally pale-yellow with white ribs.

WENTWORTH, wĕnt'wĕrth, **Benning,** English governor of New Hampshire: b. Portsmouth, N. H., 24 July 1696; d. there, 14 Oct. 1770. He was graduated at Harvard in 1715, became a merchant at Portsmouth, which town he frequently represented in the provincial assembly, was appointed a king's councillor in 1734, and when in 1741 New Hampshire was made a distinct province he became its governor. He so continued until 1767, when he resigned. He was authorized by the Crown to grant patents of unoccupied land, and in 1749 began making grants on the west side of the Connecticut River, in what is now southern Vermont. These grants were considered by the colonial government of New York as within its domain, and, as Governor Wentworth stoutly maintained for a time his authority, the collision so famous in the history of Vermont respecting the New Hamphshire grants ensued. (See VERMONT, *History*). Governor Wentworth exacted heavy fees for his grants of land, and thus accumulated a large property, and in all of them stipulated for the reservation of a lot for an Episcopal church. The town of Bennington, Vt., was named in honor of him. After his resignation as governor he gave to Dartmouth College 500 acres of land, on which the college buildings were erected. For an account of his second marriage, consult Longfellow's poem 'Lady Wentworth.'

WENTWORTH, Charles Watson. See ROCKINGHAM, 2D MARQUIS OF.

WENTWORTH, George, American mathematician, son of G. A. Wentworth (q.v.): b. 1868. He was graduated at Harvard University in 1888, and from 1894 was his father's assistant in the compilation of text-books. Since his father's death in 1906 he has collaborated with D. E. Smith (q.v.) in preparing the Wentworth-Smith mathematical series.

WENTWORTH, George Albert, American mathematician: b. Wakefield, N. H., 31 July 1835; d. Dover, N. H., 24 May 1906. He was graduated from Harvard in 1858, and in 1858–91 was professor of mathematics at Phillips Exeter Academy. With G. A. Hill he prepared a series of textbooks on algebra, arithmetic, geometry and physics, and he was author of the Wentworth Series of mathematical works comprising about 40 volumes, among which are 'Elements of Geometry' (1878); 'Surveying and Navigation' (1882); 'Higher Algebra' (1891), etc.

WENTWORTH, SIR **John,** English colonial governor of New Hampshire, and afterward of Nova Scotia: b. Portsmouth, N. H., 9 Aug. 1737; d. Halifax, N. S., 8 April 1820. He was a nephew of Benning Wentworth (q.v.). He was graduated at Harvard in 1755, being a classmate of John Adams, became a merchant, and in 1765 was the agent of New Hampshire to present petitions in England. While there he was appointed to succeed Benning Wentworth as governor of New Hampshire. At the same time he was made "surveyor of the king's woods" for all North America. Having landed at Charleston, S. C., in March 1767, he traveled through the colonies, registering in each his commission as surveyor, and arrived at Portsmouth in June. The office of governor was at that time an extremely difficult one by reason of the increasing discontent of the colonists. At the first, Wentworth's administration was very popular. He remonstrated against the taxes imposed by the English government, but sought to maintain the loyalty of the colony, and was successful in pre-

venting the assent of Portsmouth to the non-importation agreements until 1770. In this he was aided by the fact that the Portsmouth merchants were disinclined to forego such profits as they might still obtain despite the crippled state of commerce. When the last attempt was made to compel the colonies to receive East Indian tea, he took advantage of lack of instructions from the government, and had the consignee reship the cargo to Halifax. His authority ended, however, when it was learned that he had endeavored to comply with the request of Gen. Thomas Gage to obtain carpenters to construct barracks for the British troops at Boston, after Massachusetts workmen had refused the task. On Dec. 14, 1774, an armed attack was made on Fort William and Mary (now Fort Constitution) on Great Island, at the entrance to Portsmouth Harbor, and 100 barrels of powder and some cannon and muskets were taken. Wentworth finally found it advisable to withdraw to the fort, and then to a warship in the harbor. At the Isle of Shoals he prorogued the assembly, his last official act. He went to Boston, and thence, in 1775, to England. In 1783 he was reappointed surveyor of the king's woods, and in 1792 he was made lieutenant governor of Nova Scotia; he relinquished this office in 1808, but continued to reside in that country until his death. He was created baronet in 1795. As colonial governor, he chartered Dartmouth College in 1769, presenting it with 44,000 acres of land. His estate at Wolfeboro, N. H., was confiscated after his departure. Nine manuscript volumes of his correspondence are in the public records of Halifax, Nova Scotia.

WENTWORTH, John, American journalist: b. Sandwich, N. H., March 5, 1815; d. Chicago, Ill., Oct. 16, 1888. He was graduated from Dartmouth in 1836 and in the same year went to Chicago where for 25 years he was owner and editor of the *Democrat*. He studied law, was admitted to the bar in 1841, and in 1843 was elected to Congress, where he served six terms. He introduced the first steam fire engine into Chicago, was active in procuring the city charter, and was an earnest promoter of the public school system; and in 1857 and 1860 he was elected mayor. In 1861 he dissolved his connection with the *Democrat,* but did not retire from active life for many years. He gave $10,000 to Dartmouth College, and was president of its alumni in 1883; he wrote *Descendants of Elder William Wentworth* (1850) and *History of the Wentworth Family* (1878).

WENTWORTH, Thomas. See STRAFFORD, 1ST EARL OF.

WENTWORTH, William Charles, Australian patriot: b. Norfolk Island, New South Wales, Oct. 26, 1793; d. near Wimbourne, Dorsetshire, England, March 20, 1872. The son of the government surgeon at the penal colony on Norfolk Island, he was educated in England, after graduating at Cambridge University, studying law at the Middle Temple, and being admitted to the bar in 1822. Returning to Australia, he speedily gained a large law practice in Sydney, where he became a champion of the "emancipists" (liberated convicts) as against the "exclusivists" (officials) and "interlopers" (voluntary immigrants), and advocated self-government for Australia. In 1824 he was one of the founders of the *Australian,* a newspaper in which he put forth his views, and with others he formed the Patriotic Association, which campaigned against the colonial administration in both Australia and England. He was mainly responsible for the recall of the governor, Sir Ralph Darling, in 1831; and the Constitution Act of 1842, which secured self-government for the colony, was largely due to his efforts. In 1843 he became a member of the first legislative council, leading the "squatter" party. He founded Sydney University in 1852, and two years later he secured a new constitution for New South Wales. For several years thereafter he lived in England where, in 1857, he founded the General Association for the Australian Colonies, which advocated a federal assembly for all the Australian colonies. Visiting Sydney in 1861, he served briefly as president of the new legislative council. In 1862 he returned once more to England, where he continued to work for a federal parliament for all Australia until his death. His efforts were eventually culminated in establishment of the Commonwealth of Australia in 1901. His body was taken to New South Wales, the legislature unanimously according him a public funeral. He wrote *A Statistical Account of the British Settlements in Australasia* (1819); *Australasia,* a poem (1823).

WEREWOLF, wēr'wo͝olf, a human being transformed into a wolf, according to a belief which has prevailed in all ages among ignorant and superstitious communities. Herodotus, with great naïveté, tells us that when he was in Scythia he heard of a people which once a year changed themselves into wolves, and then resumed their original shape; "but," adds he, "they cannot make me believe such tales, although they not only tell them, but swear to them." But the lycanthropes of the Middle Ages, or *loups-garous,* as they were called by the French, were sorcerers, who during their wolfhood had a most cannibal appetite for human flesh. The Germans called them *Währwölfe.* Many marvelous stories are told by the writers of the Middle Ages of these wolf-men or *loups-garous,* and numerous authentic narratives remain of victims committed to the flames for this imaginary crime, often on their own confessions.

It is certain that faith in the power of witches to assume the shape of animals, such as wolves, dogs, cats, or horses, existed at a comparatively recent time. An old writer says that "the werewolves are certain sorcerers, who, having anointed their bodies with an ointment which they make by the instinct of the devil, and putting on a certain enchanted girdle, do not only unto the view of others seem as wolves, but to their own thinking have both the shape and nature of wolves, so lông as they wear the said girdle; and they do dispose of themselves as very wolves, in worrying and killing, and most of human creatures."

The werewolves were said to have in some instances a special hatred of religion and its devotees, and this, coupled with the charge of devouring human flesh, left no doubt as to the fate of anyone who fell under suspicion of being a werewolf. The superstition itself was doubtless due in part to the brutal and savage aspect of human beings who, owing to melancholia or other forms of insanity, went wild in the woods—an occurrence not infrequent in re-

mote districts in the Middle Ages. It was also in all probability connected with the belief, which was a prominent feature of mythology, in the power of the gods and inferior spirits to enter the bodies of animals, and with the doctrine of transmigration of souls, common alike to the ancient Egyptians, the followers of Pythagoras, and the Hindus. See WITCHCRAFT.

WERFEL, vĕr'fĕl, **Franz V.,** Austrian poet, novelist, and dramatist: b. Prague, Bohemia (later Czechoslovakia), Sept. 10, 1890; d. Hollywood, Calif., Aug. 26, 1945. The son of a wealthy Jewish industrialist, he was educated at the universities of Prague and Leipzig, and in 1910, because his father opposed his writing of poetry as foolishness, he left for Hamburg and secured work in a shipping house. It was at this time that he published his first book of poems, *Der Weltfreund* (1911), which was animated by the idea of the community of souls in all living things. Other poetical works followed, and he became recognized as the leader of Germany's militant group of youthful literary iconoclasts. At outbreak of World War I in 1914 he was employed as a reader by the Leipzig publishing house of Kurt Wolff. He fought in the Austrian army on the Russian front until 1917, when he was transferred to the war press bureau in Vienna. In 1918 he married Alma Marie Schindler, widow of Gustav Mahler, the composer, and after the war made his home in Vienna, where he turned to novel writing. His first work published in the United States was *Verdi* (1925), a biographical novel which was made into a motion picture in Italy. In 1926 two of his plays, *The Goat Song* and *Juarez and Maximilian,* were produced in New York City. His *Forty Days of Musa Dagh* (1933), a long novel of the heroic defense of a little band of Armenians against Turkish attempts to annihilate them, was a great success both in German and in English translation. Outspoken in his opposition to the Nazis, he was expelled from the Prussian Academy of Art in 1933; and when the Germans entered Austria in 1938 he moved to Paris. Delayed in leaving for Spain after the fall of France to the Germans in 1940, he found temporary haven at Lourdes, and there he first heard the story of Bernadette Soubirous, whose story he was inspired to write. Reaching the United States late in 1940, he turned out *Das Lied von Bernadette* (1941), translated by Ludwig Lewisohn as *The Song of Bernadette* (1942). It immediately won wide acclaim, the book being translated into seven languages, and the motion picture of it winning several awards. Another indirect result of his flight from the Nazis was a play, *Jacobowsky and the Colonel* (1944), written in collaboration with Samuel Nathaniel Behrman and produced in New York City.

Werfel's works of fiction translated into English include, besides those mentioned above, *The Man Who Conquered Death* (1927); *The Glass Reunion* (1929); *The Pure in Heart* (1929); *The Pascarella Family* (1932); *Twilight of a World* (1937); *Hearken Unto the Voice* (1938); and *Embezzled Heaven* (1940). Other dramas in English translation were *The Eternal Road* (1936) and *Paul Among the Jews* (1943). *Between Heaven and Earth* (1944) was a book of essays.

WERFF, vĕrf, **Adriaen van der,** Dutch historical and figure painter: b. near Rotterdam, Jan. 21, 1659; d. Rotterdam, Nov. 12, 1722. After studying in Amsterdam under Aart van der Neer he settled in Rotterdam where, in 1696, he attracted the notice of John William, the elector palatine; he became court painter, and in 1703 was ennobled. Among his celebrated paintings are the *Judgment of Solomon; Christ Carried to the Sepulchre; Ecce Homo; Abraham with Sarah and Hagar,* and *Magdalen in the Wilderness.* Van der Werff was particularly noted for his small historical pieces, which are most exquisitely finished, and are still in high request. His brother and pupil, PIETER VAN DER WERFF (1665–1718), painted portraits and domestic pieces.

WERGELAND, vĕr'gĕ-län, **Henrik Arnold,** Norwegian lyric poet and dramatist: b. Kristiansand, June 17, 1808; d. Kristiania (Oslo), July 12, 1845. He studied at Kristiania in 1836 became custodian of the university library, and in 1840 keeper of the Norwegian archives. He was one of the leaders of the Ultra-Norwegian party, waging war on all things Danish, but found opponents in Johan S. C. Welhaven and the latter's school. In 1830 he published the dramatic poem *The Creation, Man, and Messiah,* a work of formidable length and slight literary merit. His chief publications are the narrative poems, *Jan van Huysum's Flower-Piece* (1840); *The Swallow* (1841); *The Jew* (1842); *The Jewess* (1844), and *The English Pilot* (1844), which take high rank in Norwegian verse. His complete collected works appeared in 1852–1857, a selection in 1859.

WERGILD, in Anglo-Saxon law, a fine inflicted as a penalty for murder or maiming. The amount, which had to be paid to the next-of-kin or gild brethren, in case of death, varied according to status. The wergild for taking the life of the king was 7,200 shillings; for an eolderman, 2,400 shillings; a king's thegn, 600; and a ceorl, 200. In the Anglo-Saxon period an alderman or eolderman was a much more important personage than the alderman of today, the aldermen of all England being the first subjects of the realm, and other aldermen being governors of counties. Even kings were called aldermen. The thegn, or thane, was a minor noble, and the ceorl, or churl, a tenant-at-will of the thane, or he might be simply a serf or farm laborer. As the value of money, measured by its purchasing power, was far greater than today, the wergild for king and alderman, and even for thane, must have been prohibitory save for the wealthiest members of the community, or when the state assumed the burden of payment, as in the case of an enemy of high rank killed in war, whose relatives were able to wreak vengeance for his death.

WERNER, vĕr'nĕr, **Abraham Gottlob,** German mineralogist: b. near Bunzlau, Sept. 25, 1750; d. Dresden, June 30, 1817. In 1775 he was appointed inspector and teacher of mineralogy and mining in the Mining Academy at Freiberg, in which position he remained for the rest of his life. He was the first to separate geology from mineralogy, and to place the former on the basis of observation and experience. The geological theory with which his name is connected is that which attributes the phenomena exhibited by the crust of the earth to the action

of water, and is known as the Wernerian or Neptunian theory (q.v.), in contradistinction to the Huttonian or Plutonic. He was nominated counselor of the mines of Saxony in 1792, and had a great share in the direction of the Academy of Mining, and in the administration of public works. He published *Kurze Klassification und Beschreibung der Gebirsarten* (1787); *Neue Theorie über die Entstehung der Gänge* (1771).

WERNER, Alfred, Swiss chemist: b. Mulhouse, Alsace, Dec. 12, 1866; d. Zürich, Switzerland, Nov. 15, 1919. He was educated at the technical schools of Karlsruhe and Zürich, and became assistant at Zürich Polytechnic in 1889; later he was at the College of France, and from 1895 to 1919 he was professor at the University of Zürich. In 1913 he was awarded the Nobel Prize in chemistry. He developed an extension of the valence hypothesis, and introduced the concept "coordination number" of elements which led to valuable discoveries. He was joint author of *Ueber die räumliche Anordnung der Atome in stickstoffhaltingen Molekülen* (1891). His own works included *Beiträge Zur Theorie der Affintät und Valenz* (1891); *Beiträge zur Konstitution anorganishcher Verbindungen* (1893); *Lehrbuch der Stereocheime* (1904); *Uber die Konstitution und Konfiguration von Verbindungen hoherer Ordung* (1914).

WERNER, Anton Alexander von, German historical and portrait painter: b. Frankfurt-on-the-Oder, May 9, 1843; d. Jan. 5, 1915. He studied at the Berlin Academy at Karlsruhe, and later in Paris and Italy. He executed several state commissions after his return from Italy, and was commissioned to accompany the general staff of the Third Army corps in France during the Franco-Prussian War. He became professor at the Berlin Academy in 1875. His paintings, particularly those of the Franco-Prussian War, are of considerable historic value. Among his works are *The Capitulation of Sedan; Meeting of Bismarck and Napoleon III at Donchery; Proclamation of the German Empire at Versailles; The Congress of Berlin;* and several portraits of Emperor William II.

WERNERITE, an important rock forming mineral, occurring in cleavable-granular, indistinctly-fibrous or columnar masses, or often in large, coarse crystals. These are tetragonal prisms terminated by pyramids, and show good prismatic cleavage. The hardness is 5 to 6 and specific gravity about 2.7. The most common colors are white or gray; lilac is also quite abundant; occasionally greenish and brick red varieties are found. Wernerite is a member of the scapolite group (q.v.) and is intermediate in composition between meionite and marialite, being a silicate of aluminum, calcium, and sodium, with chlorine. It usually occurs in crystalline limestone. Among its many localities a few of the most important are Arendal, Norway; Bolton, Mass.; northern New York; Ontario and Quebec. The mineral was named in 1800 for Abraham Gottlob Werner (q.v.).

WERNHER, wûr'nĕr, Sir **Julius Charles,** British South African financier: b. Darmstadt, Germany, 1850; d. London, England, May 21, 1912. In 1871, after serving in the Franco-Prussian War, he went to South Africa on behalf of a German diamond merchant, and within a few years he became a leading figure in the Kimberley diamond-mining industry. His interests, and those of Cecil Rhodes and Alfred Beit, were amalgamated in a single firm which in 1889 became Wernher, Beit and Company. In 1898 he was naturalized a British subject, and in 1905 he was given a baronetcy. He was a liberal benefactor of educational institutions, including the South African University which, with Beit, he endowed with £500,000.

WERTENBAKER, Thomas Jefferson, American historian and educator: b. Charlottesville, Va., Feb. 6, 1879. He graduated at the University of Virginia in 1902, and after brief experience as journalist in Baltimore, Md., he taught history at the Agricultural and Mechanical College of Texas, 1907–1909, and the University of Virginia, 1909–1910. In 1910 he joined the faculty of Princeton University as instructor in American history, and successively became assistant and associate professor and, in 1925, Edwards professor of American history. From 1928 until 1936 he was also chairman of Princeton's department of American history. During 1939–1940 he was the Harold Vyvyan Harmsworth professor of American history at Oxford University. His historical works included *Virginia under the Stuarts* (1914); *Patrician and Plebeian in Virginia* (1916); *Planters of Colonial Virginia* (1922); *The American People—A History* (1926); *The First Americans* (1927); *The United States of America,* with Donald E. Smith (1931); *Norfolk—Historic Southern Port* (1931); *The Founding of American Civilization* (1938); *Torchbearer of the Revolution* (1940); *The Old South—The Founding of American Civilization* (1942); *The Golden Age of Colonial Culture* (1942).

WESCOTT, Glenway, American fiction writer: b. Kewaskum, Wis., April 11, 1901. He attended the University of Chicago during 1917–1919, and for some years thereafter he lived in Europe, principally in the south of France. He published *The Apple of the Eye* in 1924, and three years later he won the Harper prize novel contest with *The Grandmothers—A Family Portrait.* Volumes of short stories included *Good-Bye Wisconsin* (1928) and *Fear and Trembling* (1932). Subsequent novels were *A Calendar of Saints for Unbelievers* (1932) and *The Pilgrim Hawk* (1940). The poetic instincts which imbued him as a young man are reflected in the delicate prose of his later works.

WESEL, vā'zĕl, Germany, a town of Prussia, on the right bank of the Rhine at its confluence with the Lippe, 35 miles northwest of Düsseldorf. It is an important railroad and river traffic center. Most fortifications were demolished in 1890, and the remainder after World War I. The Berlin gate, with statues of Hercules and Minerva, dates from 1722. Wesel contains several ancient buildings. The Church of St. Willibrord, founded in the 12th century, took its present form in 1521; it was restored in 1883–1896. The town hall, with a Gothic façade, was completed in 1390. A former French church became the Lower Rhine Museum. Clothing, wire, machinery, and pianos are among the principal industries. The town, formerly known as Lippemünde, was a settlement of the early Saxons. It was incorporated in 1241, and later was a

member of the Hanseatic League. In 1540 it adopted the Reformation. The Spaniards, Dutch, and French occupied it at various periods, and in 1814 it passed into the possession of Prussia. Pop. 24,047.

WESER, vā'zĕr (Latin, *Visurgis*), a river of Germany, formed by the junction of the Fulda and Werra at Münden, Prussia. It flows tortuously first northwest, then northeast between Westphalia and Brunswick, and after a circuitous northwestern course it traverses the town of Bremen, forms the boundary between Hanover and Oldenburg, turns almost due north at Elsfleth, and falls by a wide mouth, incumbered with sandbanks, into the North Sea. With the Werra, it is about 465 miles in length; but the Weser proper has a length of 280 miles. The lower part of the river, from Bremen to Bremerhaven, has been deepened and improved for large vessels. It is navigable by barges to some distance up both head-streams; but Hameln is the practical limit of summer navigation.

WESLEY, Charles, English Methodist preacher and famous hymn writer: b. Epworth, Lincolnshire, Dec. 18, 1707; d. London, March 29, 1788. The 18th child of Samuel Wesley (q.v.), rector of Epworth, he was the youngest brother of John Wesley (q.v.). He was educated at Christ Church, Oxford, and there he began, he says, "to observe the method of study prescribed by the university," adding, "This gained me the harmless nickname of Methodist" —a word at first apparently without religious significance, and meaning one who affected method. Ordained priest in the Church of England in 1735, he accompanied his brother to Georgia to become secretary to Governor (James Edward) Oglethorpe. Failing health necessitated his return to England in 1736, and he was appointed unlicensed curate of Saint Mary's, Islington, London. On May 21, 1738, he experienced an evangelical conversion, and for some years thereafter he was an active itinerant preacher and undertook the writing of a large number of hymns. He differed from his brother on some doctrinal and other points, holding, for example, that perfection must be attained by a gradual process. Between 1756 and 1771 he labored chiefly in the vicinity of Bristol, and thereafter he lived in London. He is said to have written some 6,500 hymns, of which many came into general use; they included *Jesus, lover of my soul* and *Love divine, all love excelling.* Consult biographies by Thomas Jackson (1849) and John Telford (1866).

WESLEY, John, English evangelical preacher, founder of Methodism: b. Epworth, Lincolnshire, June 17, 1703; d. London, March 2, 1791. He was the 15th child of Samuel Wesley (q.v.), rector of Epworth, and elder brother of Charles Wesley (q.v.). From Charterhouse, he went to Christ Church, Oxford University, where he graduated in 1724. The next year he was ordained deacon in the Church of England and became a Fellow of Lincoln College, in which he was appointed Greek lecturer and moderator. He was of a serious and religious turn of mind, and books which impressed him powerfully were the *Imitatio Christi* and Jeremy Taylor's *Holy Living* and *Holy Dying.* He took priest's orders in 1728, and about the close of 1729 was called from acting as his father's curate to perform the duties of his fellowship in person. At Oxford he found an association of students of which his brother Charles was a member. It was known by various nicknames, among which were the Holy Club, the Bible Moths, the Sacramentarians, and the Methodists. It appears that all the association did at this time to earn these opprobrious epithets was to meet on Sunday evenings to read the Scriptures, and on other evenings to read secular literature. John Wesley joined this society, which gradually became exclusively religious in its object, and highly ascetic in its tone. Its members fasted twice and communicated once a week, visited prisons and the sick, and engaged frequently in prayer, meditation, and self-examination. Among the members were James Hervey and George Whitefield. At the time John Wesley joined it the society numbered very few members, but it gradually increased, though it never became a large body. This induced him to decline his father's living at Epworth, that he might continue to exercise his influence at the university. During his residence at Oxford he became acquainted with William Law, author of the *Serious Call to the Unconverted,* who exercised much influence over him. In 1735 he accepted an invitation from Governor (James Edward) Oglethorpe to preach to the colonists of Georgia. He sailed on December 10 with his brother Charles and a considerable body of German Moravians. During his visit to the colony he paid his addresses to Sophia Hopkey, niece of the chief magistrate of Savannah, or rather, as the story is told, received her advances with favor, but ultimately declined to marry her. Miss Hopkey married a Mr. Williamson, and Wesley, without assigning a reason, refused to admit her to the communion. Her husband threatened legal proceedings, which were not enforced, but Wesley, on account of this event, left the colony, "shaking the dust from his feet." He reached England Feb. 1, 1738, just as Whitefield, under whose preaching Methodism had made great progress, sailed for Georgia. At this time an important event took place in the inner religious life of Wesley. He was converted, according to his own account, about a quarter to 9 o'clock on the evening of May 24, 1738, at a meeting in Aldersgate Street, London, to which he had gone very unwillingly, while Martin Luther's *Preface* to the Epistle to the Romans was being read. On June 13 he set out for Germany to visit Herrnhut, the village in Saxony of Moravians from Bohemia. He met Count Nikolaus Ludwig von Zinzendorf at Marienborn, spent a fortnight at Herrnhut, and returned to England about the middle of September. Whitefield returned from Georgia soon after, and became intimately associated with Wesley. He began open air preaching near Bristol in the following February, and his example was soon followed by Wesley. On Nov. 11, 1739, Wesley first preached at the Foundry, a disused structure in Moorfields, London, formerly employed by the government for casting brass ordnance. This he enlarged and repaired, and until 1778 it remained the Methodist headquarters in London. Somewhat later he founded the "United Society," for week day meetings. From the beginning of this society the inception of Methodism is generally dated.

In July 1740 Wesley separated from the Mo-

ravians on account of doctrinal differences. He soon afterward separated from Whitefield, but without a permanent personal breach. Wesley had now sole control of the religious body which adhered to him, and he devoted his entire life without intermission to the work of its organization, in which he showed much practical skill and admirable method. His labors as an itinerant preacher were incessant. He had no permanent residence, and would ride horseback from 40 to 60 miles each day, never intermitting his journeys on account of the weather. Often he preached four or five times a day, using the simplest words but appealing overwhelmingly to the heart and conscience. Besides traveling throughout England, he made no less than 42 trips to Ireland and 22 to Scotland. He sent two of his preachers to the North American colonies in 1769, and two years later Francis Asbury crossed the Atlantic to become general superintendent of his work in America. In 1784 he completed a "deed of declaration" which placed the Methodist organization on a legal basis, and the same year he ordained presbyters and appointed Thomas Coke along with Asbury superintendent of the Methodist Church in America. He married in 1750 Mary Vazeille, a widow with four children, but his habits of life, which he did not attempt to accommodate to his wife, produced an alienation, and they finally separated. Wesley held strongly to the principle of episcopacy, though not a believer in the apostolic succession; and he never formally separated from the Church of England.

His writings were of the most miscellaneous character, including grammars, an English dictionary, biographies, and manuals of history, logic, and medicine. He also published 23 collections of hymns; they are included in the *Poetical Works of John and Charles Wesley* (1868–72). In 1780 he commenced a monthly, the *Arminian Magazine,* which he edited during his life and which, after his death, was merged in the *Methodist Magazine.* Against pre-Revolutionary troubles in America he directed *A Calm Address to Our American Colonies* (1775), *A Calm Address to the Inhabitants of England* (1777), and *A Serious Address* (1778). His itineraries and spiritual life were recorded in his remarkable *Journal* between 1735 and 1790; N. Curnock edited an 8-volume edition, 1909–16. E. H. Sugden edited Wesley's *Standard Sermons* (1921). Consult Telford, J., *Life of John Wesley* (1924); Simon, J. S., *John Wesley, the Master Builder* (1927); Thompson, D. D., *John Wesley as a Social Reformer* (1928). See also METHODIST CHURCHES OF THE WORLD.

WESLEY, Samuel, English clergyman and poet: b. Winterborne-Whitchurch, Dorsetshire, Dec. 17, 1662; d. Epworth, Lincolnshire, April 25, 1735. He was the father of Charles, John, and Samuel Wesley (qq.v.). He graduated from Exeter College, Oxford, in 1688, and was ordained priest in 1690; he became rector of South Ormsby, Lincolnshire, in that year, and in 1695 of Epworth in the same county. He wrote *Life of Christ: An Heroic Poem* (1693); *Eupolis's Hymn to the Creator* (1778); and other works, including the posthumous *Dissertationes in Librum Jobi* (1735). He is best known by the two hymns to be found in Methodist hymn books, *Behold the Saviour of Mankind* and *O, Thou, Who, When I Did Complain.*

WESLEY, Samuel, English classical scholar and poet: b. Spitalfields, London, Feb. 10, 1691; d. Tiverton, Devonshire, Nov. 6, 1739. He was the eldest son of Samuel Wesley (q.v.) and brother of Charles and John Wesley (qq.v.). After graduating at Christ Church, Oxford University, in 1715, he became head usher at Westminster School. He was ordained in the Church of England, and in 1732 he was appointed headmaster of Blundell's School, at Tiverton, where he served until his death. Although he did not embrace Methodism with his brothers, writing of it as "a spreading delusion," many of his hymns appear in the Methodist hymnal. His *Poems on Several Occasions* (1736) was reprinted in 1808 and 1862. Other volumes included *The Christian Poet* (1735). Consult Tyerman, *Life and Times of Samuel Wesley* (1866).

WESLEYAN COLLEGE, Macon, Ga., an institution of higher learning for women, founded in 1836 as the Georgia Female College. It is owned and controlled by the Georgia and Florida Conferences of the Methodist Episcopal Church of the South. It claims to be the first college in America to confer a degree upon a woman (1840). It offers courses for the B.A. and the B.S. degrees. About 600 enroll annually.

WESLEYAN METHODIST CONNECTION OF AMERICA, known commonly as the Wesleyan Methodist Church. See METHODIST CHURCHES OF THE WORLD.

WESLEYAN METHODISTS. See METHODIST CHURCHES OF THE WORLD, section on *Wesleyan Methodist Church.*

WESLEYAN UNIVERSITY, located at Middletown, Conn., was established in 1831 under the auspices of the Methodist Episcopal Church, being the first educational institution of collegiate grade established by that church in the United States. The institution, however, has no organic relation with any church, and its charter provides that it shall be absolutely nonsectarian. The founders of the university were offered the buildings of the American Literary, Scientific, and Military Institute (from which Norwich University, in Vermont, developed) if an endowment of $40,000 were raised; the gift was accepted and its condition complied with. During 1868–1878 the university's material resources were largely increased and several new buildings erected; and in 1903–1916 several additional buildings were erected and the endowment funds doubled; in 1919–1920 a campaign for $3,000,000 for endowment and buildings was launched. In the last decade the gifts for endowment and equipment have exceeded the total gifts received in the university's first century. Resources now exceed $15,000,000. The university offers courses leading to the degrees of B.A. and M.A. Requirements for generalization, applying in the first two years of the undergraduate course, provide that the student shall pursue introductory courses in several departments. For the work of the last two years a concentration requirement prescribes that the student shall select the major portion of his studies in a closely related group of departments in order to acquire a considerable mastery of at least one field of study. Distinction work is also

provided to encourage still greater thoroughness and to develop the student's initiative. In 1937–1938 the Honors College was established to direct and make more effective this work for distinction. There are five fellowships, and the trustees supplement the income from a large number of endowed scholarships by a special budget appropriation, making possible scholarship awards amounting to about $60,000 to students considered worthy of such assistance. There are a John Wesley Club and 12 Greek letter fraternities, which have their own houses, where many of the students live. The university has a campus of more than 50 acres on high ground at the western edge of the city, overlooking the Connecticut River. The buildings include North College, Clark Hall, Harriman Hall, and two smaller buildings used as dormitories; South College, the administration building, and the only one surviving from the old military academy; Memorial Chapel in honor of the students who gave their lives in the Civil War; '92 Theatre-Rich Hall; Olin Library; Hall Laboratory of Chemistry; Shanklin Laboratory of Biology; Van Vleck Observatory, with a 20-inch refracting telescope; Scott Laboratory of Physics; Judd Hall, which houses a valuable museum and the departments of Geology, Music, and Psychology; Willbur Fisk Hall, with recitation rooms; Fayerweather Gymnasium; Alumni Athletic Building, and Squash Racquets Building; Downey House with dining room, grill room, postoffice, Book Nook, and social rooms; Davison House, a homelike infirmary with modern medical equipment; Russell House, used by the Honors College; Winchester House, providing offices for student publications, the Alumni Council, Christian Association, modern language clubs, and the Outing Club; and other auxiliary buildings. The enrolment at Wesleyan is limited to about 900. The total resources of the university at the end of the fiscal year 1938–39 amounted to $13,475,115; the productive funds to $7,703,082; income to $864,814. Gifts for the year amounted to $452,144. Enrolment was 749 in the autumn of 1939.

James L. McConaughy,
President, Wesleyan University.

WESSEL or **WESSEL GANSFORT,** vĕs'ĕl gäns'fôrt, Dutch theologian and pre-Lutheran reformer: b. Groningen, 1420?; d. 1489. His first name may have been Johann (Johannes). He passed the latter part of his life in retirement in his native country, part of the time in convents. He was a decided opponent of the scholastic theology and was in intimate relations with some of the prominent humanists, as Agricola and Höck, yet in his own views he leaned strongly toward mysticism. He regarded Christianity as something entirely spiritual, confined to a man's own heart and God. The Scriptures, according to him, are the living source of all true faith; the church is based upon a compact; there is a general priesthood of the rational universe; faith is to be reposed only in an orthodox pope and not in every council; sin can be forgiven by none but God; excommunication has only an external influence; indulgences refer only to ecclesiastical penalties; the true satisfaction for sin is a life in God; and purgatory is nothing but the purifying influence of a longing after God. After his death some of his works were burned as heretical; his *Farrago Rerum Theologicarum* was published with a preface by Luther (1522). The most complete edition of his works is that edited by Lydius (1617). Consult Muusling, *Commentatio Historica-Theologica de Wesseli* (1831); Ullmann, *Reformatoren vor der Reformation* (1847).

WESSEX, wĕs'ĕks, a kingdom of Anglo-Saxon England, one of the most important of the heptarchy (q.v.). It covered the country between the valley of the Thames and the south coast, excepting the kingdoms of Kent and Sussex. Wessex, signifying West Saxons, was founded by Cerdic, who landed near Southampton in 495 and with the aid of his son, Cynric, established his rule in the southern part of what later became Hampshire. Later kings extended Wessex to the north and south, and Egbert, who became king in 802, overthrew the kingdom of Mercia and in 829 was recognized as bretwalda (q.v.). Attacks on England by Danes or Northmen gradually developed, until by 870 they had practically mastered the northern kingdoms and East Anglia. Then began the struggle for Wessex, in which Alfred the Great, who had become king of Wessex in 871, proved victorious. At his death in 899 the king of Wessex was in fact the master of all England west and south of a line drawn roughly from Chester to London, and his sovereignty was also vaguely acknowledged over the rest of the country, known as the Danelagh (q.v.). It remained for Alfred's son, Edward (Eadward) the Elder, to translate this sovereignty into a definite mastery, the king of Wessex becoming king of England.

The Wessex which is the scene of the novels of Thomas Hardy (q.v.) is the southwestern area of England, principally the county of Dorsetshire. See Egbert; England.

WEST, Andrew Fleming, American philologist: b. Allegheny, Pa., May 17, 1853; d. Princeton, N. J., Dec. 27, 1943. In 1874 he graduated at Princeton University, and he served there as professor of Latin from 1883 until his retirement in 1928. He was largely instrumental in establishment of Princeton's graduate school in 1901, and he was also its dean until 1928. He planned the Graduate College of Princeton, which was opened in 1913. For many years he was chairman of the board of trustees of the American Academy in Rome. He edited Terence's *Andria* and *Heautontimoroumenos* (1888) and *The Philobiblon of Richard de Bury* (1889), and his numerous books included *Alcuin and the Rise of the Christian Schools* (1893); *Stray Verses* (1931); and *American General Education* (1932).

WEST, Benjamin, Anglo-American painter: b. Springfield, Pa., Oct. 10, 1738; d. London, March 11, 1820. After some instruction from William Williams, a painter of Philadelphia, he established himself in that city, but in 1759 moved to New York. In 1760 he sailed for Europe, and there he remained for the rest of his life. For three years he was in Italy, among the paintings he executed while in Rome being *Cimon and Iphigenia* and *Angelica and Medora.* He paid a visit to London in 1763, and there was so well patronized that he made it his permanent home. He painted *Agrippina Landing with the Ashes of Germanicus* for Archbishop Drummond

of York, who introduced him to George III. The king became his steadfast patron, and in 1772 appointed West his historical painter. He was one of four artists to submit to the king a plan for a royal academy, and became an original member of the institution. After the death in 1792 of Joshua Reynolds, his close friend, he was elected to succeed him as president of the Royal Academy. In his *Death of General Wolfe* (Grosvenor Gallery, London) the figures were in modern costume, this being a departure from the practice then current of depicting characters in Greek or Roman dress. West painted a series of historical works for Windsor Castle, and for its chapel a series on the progress of revealed religion; he had finished 28 pictures for the chapel and sketched the remainder when George III became insane and the order for painting the religious series was rescinded. Other pictures of the 400 which he painted included *Christ Healing the Sick* (National Gallery, London); *The Crufixion, The Ascension,* and *Death on the Pale Horse* (Pennsylvania Academy of Fine Arts, Philadelphia); *Departure of Regulus from Rome* (Hampton Court Palace, London); *Penn's Treaty with the Indians* (Independence Hall, Philadelphia); *King Lear* (Boston Museum of Fine Arts). One of the finest of his historical pieces was *The Battle of la Hogue.*

WEST, Rebecca, pseudonym of CICILY ISABEL FAIRFIELD, English novelist, critic, and essayist: b. County Kerry, Ireland, Dec. 25, 1892. After attending George Watson Ladies' College, Edinburgh, she was on the London stage for a short time, at that period adopting as her pseudonym the name of the heroine in *Rosmersholm,* the play by Henrik Ibsen. Turning to journalism in 1911, she was first a reviewer for the *Freewoman,* and subsequently contributed literary criticism and political articles to many English and American newspapers and magazines. Her comments on books, men, and affairs were sometimes none too kindly. In 1930 she married Henry Maxwell Andrews, a London banker. Her first book was *Henry James* (1916), and this was followed by a war novel, *The Return of the Soldier* (1918), which won high praise. Later novels included *The Judge* (1922), *Harriet Hume* (1929), and *The Thinking Reed* (1936). Besides studies of D. H. Lawrence (1930) and St. Augustine (1933), her works of non-fiction included *The Strange Necessity* (1928) and *Ending in Earnest* (1931), the latter published only in the United States. She also wrote the text for two books of cartoons by David Low—*Lions and Lambs* (1928) and *The Rake's Progress* (1934). During 1937 she visited Yugoslavia, and her impressions of that country she published in the two-volume *Black Lamb and Grey Falcon* (1942). A novel, *The Fountain Overflows,* was published in 1956.

WEST, Thomas, 3D (OR 12TH) BARON DE LA WARR. See DE LA WARR, THOMAS WEST.

WEST ALLIS, city, Wisconsin, in Milwaukee County, just west of Milwaukee, on the Chicago, Milwaukee, St. Paul and Pacific and Chicago and North Western railroads. It manufactures automobiles, trucks, tractors, engines (diesel and others), machinery, steel castings, turbines, and wheelbarrows. It has a mayor and council. Pop. (1950) 42,959.

WEST BEND, city, Wisconsin, Washington County seat, altitude 910 feet, on a western bend of the Milwaukee River; the Chicago and North Western Railroad, and one federal and two state highways; 35 miles north of Milwaukee, in a farming, dairying, and stock-raising region. The chief manufactures are aluminum ware, farm machinery, pocketbooks and other leather goods. About 1845 there was a settlement here with a sawmill and a gristmill. The city has a mayor and council. Pop. (1950) 6,849.

WEST BENGAL, state of the Republic of India, formed by the partition of the old province of Bengal when India became independent in 1947. Stretching from Nepal and the Himalayas in the north to the Bay of Bengal in the south it is bounded on the northeast by Assam and on the east by Eastern Pakistan. It comprises an area of 33,945 square miles. Except in the extreme north it is a flat thickly populated alluvial plain comprising most of the Gangetic delta. Calcutta (q.v.), the capital, is the largest city in India and an important port.

The climate is hot and humid. The staple crop is rice; other crops are wheat, pulses, oilseeds, potatoes, sugarcane, jute and tobacco. The principal industries are jute, tea, coal, cotton textiles, paper, rubber, and engineering, most of which are located in greater Calcutta. There are small scale silk, metal, paper and mat industries. Pop. (1951) 26,306,602.

WEST BROMWICH, brŭm'ĭch, a manufacturing town, England, in Staffordshire, between Wednesbury and Birmingham. The principal buildings include the town hall with a massive tower; a number of fine modern churches; several chapels of different denominations; public schools; an institute, art and technical schools, a free library and a hospital. There is a fine public park. West Bromwick has a share in the mining and manufacturing industries of this busy district and has grown largely of late years, carrying on the manufacture of iron goods of various kinds, such as smelting and brass founding. It was an important center of arms manufacture during World Wars I and II. Pop. (1951) 87,985.

WEST CHESTER, borough, Pennsylvania, Chester County seat, altitude 455 feet, on the Pennsylvania Railroad and two federal and three state highways, 25 miles west of Philadelphia and 16 miles north of Wilmington. A settlement here about 1713 was originally called Turk's Head, and the Turk's Head Inn (1762) is still standing. In 1784 the county was divided and the newly named West Chester became seat of the old county—Chester becoming county seat of Delaware County. West Chester became a town in 1788 and a borough in 1799. There was fighting hereabouts in the Revolutionary War—in 1777 at Brandywine, 7 miles to the south, and at Paoli, 8 miles to the northeast. The surrounding country is rich farm land with nursery and fruit farms, dairying, stock raising, and a large production of mushrooms. West Chester has a number of manufacturing establishments, and the major products include lumber and millwork, wheels, machinery and foundry products, gas engines, air compressors, cabinets, hosiery, paper boxes, tags, lead crayons, and canned goods. The West Chester State Teachers College was estab-

lished here in 1871. The borough is governed by a mayor and council. Pop. (1950) 15,168.

WEST CHICAGO, city, Illinois, Du Page County, 30 miles west of Chicago. In an agricultural area, the city has railroad shops as well as manufactures of portable buildings, builders' supplies, rare-earth chemicals, gas mantles, and lighting fixtures. One of the Lincoln-Douglas debates was held here in 1858. Settled in 1849, it was incorporated 1906. Pop. (1950) 3,973.

WEST COVINA, city, California, in Los Angeles County; 18 miles east of Los Angeles. It is situated in a farm area producing citrus fruits and walnuts. The city was incorporated in 1923. Pop. (1950) 4,499.

WEST DES MOINES, city, Iowa, in Polk County; altitude 814 feet; 5 miles west of Des Moines; on the Minneapolis and St. Louis, and the Chicago, Rock Island and Pacific railroads. Its industrial products are cement, cement tile, and clay pipe. The present name replaced the original one, Valley Junction, in 1938, by popular vote. Pop. (1950) 5,615.

WEST FLANDERS. See FLANDERS, WEST.

WEST FLORIDA, that part of the English possessions in Florida in 1763 west of the Apalachicola River, bounded on the west by Lake Pontchartrain, the Mississippi, and Lake Maurepas, and on the north by the 31st parallel of latitude. In 1763 it was made into a separate administration district. The governor had the power of convening general assemblies. Laws were made by the governor with the approval of an advisory council and the general assembly. During the Revolutionary War, West Florida sided with the British crown; in 1780 it was attacked by the Spaniards, and by 1782 the British were driven out. By the treaty of 1783, in which England acknowledged the independence of the United States, Spain was permitted to retain Florida but a secret clause of the treaty made the southern boundary of the United States the 31st parallel instead of the line 32° 28′ as had been fixed in February 1764. Spain refused to evacuate the portion between the two lines and a bitter dispute followed with the United States which nearly resulted in hostilities. Finally Thomas Pinckney succeeded in negotiating a treaty by the terms of which the 31st parallel was acknowledged as the boundary of West Florida, while the United States assumed all claims against Spain by citizens of Georgia for spoilation. A new disagreement with Spain developed in 1803 when the United States claimed that part of West Florida west of the Perdido River as part of the Louisiana Territory which it had just purchased from France. The dispute dragged on until in 1810 the part of West Florida between the Perdido and the Mississippi declared its independence of Spain and became the Republic of West Florida. This mushroom state was seized by the United States, and law and order were restored to the distracted region. The part west of Pearl River became part of the Territory of Orleans. In 1812 West Florida was added to Louisiana and the part between the Perdido and Pearl rivers was annexed to the Territory of Mississippi. In 1812 English troops had their base in the Floridas in their operations against the United States. Andrew Jackson drove them out in 1814 and took Pensacola. During the Seminole War, Jackson again occupied a part of West Florida. The province was administered by United States officials appointed by Jackson until 1819 when it was returned to Spain. In 1819–1821 negotiations for the purchase of Florida were undertaken by the government of the United States. On July 17, 1821, Spain ceded all her claims to the United States, and in 1822 the portion of West Florida east of the Perdido was incorporated in the Territory of Florida.

Consult Fairbanks, G. R., *History of Florida* (1871); Green, E. L., *History of Florida* (1898); Fuller, H. B., *Purchase of Florida* (1906).

WEST FRANKFORT, city, Illinois, in Franklin County; 305 miles southwest of Chicago; on the Burlington; Chicago and Eastern Illinois; and Illinois Central railroads. It is the center of a large coal mining area. The United Mine Workers of America maintain a hospital here. The city has a public library, a stadium for sports, and a choral club to promote musical interests. A stone marker here bears the legend, "Last Battle of the Kaskaskia and Shawnee Indians, 1802." Pop. (1950) 11,384.

WEST HAM, a county borough of England and an east suburb of London. It covers an area of 4,683 acres. Both West Ham and East Ham are important industrial centers. Pop. (1951) 170,987.

WEST HARTFORD, town, Connecticut, in Hartford County; altitude 100 feet; adjoins Hartford on the west; served by the New York, New Haven and Hartford Railroad. It is a shipping center for the surrounding district, which is interested in tobacco culture, dairying, and truck farming. Manufactures include nipples, steel balls, burial vaults, tools and dies, and sheet metal products. The public library is a memorial to Noah Webster (q.v.), who was born here. Pop. (1950) 44,402.

WEST HAVEN, town, Connecticut, in New Haven County, altitude 27 feet, adjacent to the city of New Haven on the southwest. It is chiefly a residential center, but has several industries including elastic fabrics, pipe organs, beer, and glazed paper. West Haven, separated from New Haven in 1822 and united with North Milford to form the town of Orange, was incorporated as a borough in 1873, returned to Orange town in 1911, and was chartered as an independent town in 1921. West Haven was the home of General Tom Thumb, the famous midget. The place was raided by the British under General Tryon in July 1779. Pop. (1950) 32,100.

WEST HAVERSTRAW, village, New York, in Rockland County, directly northwest of Haverstraw, near the west bank of the Hudson River. Chemicals, textiles, and clothing are manufactured. In the village is a state home for crippled children. The area was incorporated in 1883. Pop. (1950) 3,099.

WEST HAZLETON, borough, Pennsylvania, in Luzerne County; altitude 1,680 feet; a suburb of Hazleton (q.v.); on the Lehigh Valley Railroad. It is a residential borough, with small

local industries; nearby are anthracite mining regions. The borough was incorporated in 1889. Pop. (1950) 6,988.

WEST HELENA, city, Arkansas, in Phillips County; altitude 121 feet; three miles west-northwest of Helena; served by the Missouri Pacific Railway, and located on federal highways. Lumber milling is done here, as well as manufacturing of wood products. Founded 1909, the city was incorporated in 1917. Pop. (1950) 4,499.

WEST HOBOKEN, New Jersey, part of Union City in Hudson County; formerly a separate town; merged with Union Hill and incorporated as Union City in 1925. It adjoins the city of Hoboken, and stands on a rise of land a mile back from the west shore of the Hudson River. There are numerous small factories.

WEST HOMESTEAD, borough, Pennsylvania, in Allegheny County; altitude 852 feet; on the Monongahela River; adjacent to Homestead; on the Pittsburgh and Lake Erie, and the Baltimore and Ohio railroads, with yards of the Union Railroad (of Pittsburgh). There are steel mills and factories. Pop. (1950) 3,257.

WEST IN AMERICAN HISTORY, The, In its historical context, the American West must not be viewed as a fixed area, but as a series of westerly moving zones each representing a more advanced stage in the evolution of society from primitive to complex forms. Between 1607, when the first assault on the wilderness that is now the United States was made by Anglo-American pioneers, and 1890 when the director of the census announced that an unbroken line no longer separated the settled from the unsettled portions of the continent, these zones constantly receded, leaving behind them a fully developed civilization. During these three centuries of frontier experience the American people were endowed with many of the traits and institutions that distinguish them today.

Opportunity was the magnet that drew men from Europe or the eastern United States into the sparsely settled West, for there nature's bounties were so abundant that the individual needed only his own brawn, brains, and courage to improve himself economically and socially. This was present in a variety of forms, and these in turn accounted for the nature of the zones that were discernible within the frontier area. Far to the west, along the cutting edge of civilization, roamed trappers and fur traders seeking wealth in the form of deer or buffalo hides, and shiny packs of beaver pelts. Behind them, wherever conditions warranted, came the miners, searching streams and mountain slopes for the tell-tale glint of dull metal that might spell a fortune in gold or silver or lead. Not far to the rear of the prospectors were the cattlemen in quest of lush fields where they could fatten their roaming herds without the restraint of farmers' fences. These shock troops of civilization made little impression on the wilderness; instead they succumbed so completely to the forces of nature that they reverted to a primitive way of life resembling that of the Indians.

This was not the case with the next wave of settlers: the pioneer farmers. Restless nomads impelled westward by a desire for self-improvement or the search for adventure, they viewed the wilderness as an enemy of progress; to them every tree was a barrier between themselves and civilization. So they cut away the forests or broke the prairie sod, built their cabins, raised their crops, and then succumbed to restlessness again as neighbors pressed in on them. When they moved on to begin the process anew they sold their "improvements" to "equipped farmers" who were blessed with both stability and capital. These permanent settlers completed the forest clearings, fenced their fields, built homes, and financed roads that would connect their communities with eastern markets. As commercial activity quickened a final group of frontiersmen appeared as though by magic—merchants and millers and distillers and lawyers—to scatter villages through the back country. With their coming the region automatically became part of the East; to the westward their counterparts were already wresting a new West from nature.

When this process began in the early 17th century the "East" was Europe and the "West" the strip of coastal lowlands that hugged the Atlantic. From beachheads established at Jamestown in Virginia, St. Marys in Maryland, Plymouth and Boston in Massachusetts, and at other isolated points Anglo-American pioneers began their assault on the vast forests that extended limitlessly westward. For a time they seemed destined to lose their battle with nature; Englishmen died like flies at Jamestown as they went through the "seasoning" process which gave them immunity to America's disease and knowledge of the techniques needed to combat its wilderness. Yet within half a century the battle was won and the first West conquered, for by the 1670's the coastal plain and river bottoms were occupied by sturdy farmers busily producing tobacco in the South and cereals and livestock in the North.

So persuasive was the environmental influence that even within this short span a frontier pattern had evolved. That of Virginia was typical. Far to the west, beyond the "fall-line" where waterfalls checked direct navigation from the sea, lay an unoccupied wilderness where fur traders roamed in their perpetual quest for deer hides and beaver pelts. Along the fall-line herdsmen pastured their cattle in pea-vine marshes or fields cleared by the Indians, moving, as one traveler put it, "(like unto the ancient patriarchs or the modern Bedouins in Arabia) from forest to forest in a measure as the grass wears out or the planters approach them." East of cattle frontiers lay a band of small farms where half-cleared fields produced corn and other grains. Still farther eastward was a land of larger farms, owned by prosperous planters who lived in elaborate manor houses, grew tobacco with hired labor, and invested their profits in imported luxuries that would allow them to ape the English country gentry. Hugging the coastline were bustling towns where merchants fattened on the growing trade between the interior and Europe.

By the time this first West was won pioneers were beginning the conquest of a new West that lay beyond. The occupation of the hilly upland that comprised the Appalachian Mountain system and its foothills began in the 1670's when a growing population advanced lowland prices to the point that younger sons, freed servants, and new arrivals from Europe could no longer afford land there. As they moved they found themselves in a new environment, so distant from the coast

that the influence of their European heritage rapidly waned. Thus freed from tradition, they adopted practices adjusted to the strange new world in which they found themselves; they abandoned frame houses for log cabins, clothed themselves in deer skins rather than imported fabrics, developed the "long rifle" and the ax as essential tools, and became so familiar with the forest that they seemed more at home there than in the lanes of Boston or New York. Their divorce from the past was hastened with the arrival in the back country of two alien groups—the Scotch-Irish from Ulster and the Palatines from Germany—who migrated in large numbers during the early 18th century and moved directly to the interior in quest of cheap lands. As in all frontier communities, this mingling of racial strains strengthened the social order by allowing each to contribute something to the resulting civilization. The great "Palatine barns" of the Germans and the roving "circuit-riders" of the Scotch-Irish typified the contributions of these groups to the American way of life.

Frontiersmen from the outer fringes of this West were ready to push beyond the Appalachians by the mid-18th century, but for a time they were held back as England won the region from France (1763) and English statesmen struggled to devise a settlement policy that would not provoke Indian retaliation. In the end this system broke down, as would all designed to hold frontiersmen back when good lands lay ahead, and by 1775 pioneers were pouring through the mountain gaps to build their communities about the Forks of the Ohio, in modern West Virginia, in the Blue Grass country of Kentucky, and in eastern Tennessee. For a time they were driven back by Indian fighting during the Revolutionary War, but so compulsive was their eagerness to move westward that migration began with a lull in the warfare after 1778. By the close of the revolution some 25,000 persons lived in Kentucky, while settlements straggled westward from Pittsburgh and engulfed both eastern Tennessee and lands about Nashville.

A sympathetic government paved the way for the next major migrations by drafting the Ordinance of 1785 which allowed settlers to buy surveyed lands and the Ordinance of 1787 which provided for the eventual division of the West into states. Thus assured of clear land titles and political equality, pioneers swept westward in a mighty flood between the 1790's and 1810, filling western New York, peopling Ohio, Kentucky and Tennessee with enough newcomers to justify statehood, and forming a thin line of settlements in southern Indiana and Illinois. Only another war—the War of 1812—checked the flood as Indians seized the opportunity to fight back against usurpation of their hunting grounds. In the end the red men lost more than they gained, for their decisive defeat during the war so broke their spirit that they retreated once more, opening most of the Mississippi Valley to settlement.

The "Great Migration" that resulted after 1815 flowed in two directions. One was toward the fertile "Lake Plains" country where pioneers from the upper South, the Northeast, and Germany met and mingled to create a new society that showed the stamp of all of the civilizations that contributed to its strength. By the end of the 1840's the whole area north of the Ohio had been carved into states, while Missouri and Iowa were also sufficiently peopled to earn a place in the Union. In all self-sufficient, small-scale agriculture emphasizing cereals and livestock was the rule, while all reflected the democratizing influence of these economic units by constitutions barring slavery (save in Missouri), providing for manhood suffrage, and assuring popular control of the legislative, executive, and even judicial branches of government.

The civilization evolving from the second post-1815 migration—that into the plains that bordered the Gulf of Mexico between western Georgia and Louisiana—differed markedly. There newcomers were drawn almost solely from the Southeast, as the existence of slavery deterred the coming of Northerners or Europeans. There the objective of each pioneer was not self-sufficiency but the production of salable surpluses in the form of cotton. As this profitable crop could be most economically grown on large-scale agricultural units, there was a tendency in all-good soil areas to consolidate holdings into plantations of about one thousand acres, even along the fringes of settlement. This process meant a constant displacement of small farmers who were driven westward to virgin lands. The Gulf Plains were settled rapidly as a result—Alabama, Mississippi, and Louisiana were all states before the end of the 1820's and Arkansas followed in 1836—but the social system that evolved denied the pioneer his birthright by barring him from the best lands and foisting on him an aristocratic political philosophy geared to the defense of slavery.

The westward movement in both the Gulf States and Lake Plains came to a halt when settlers reached the western edge of the first tier of states lying beyond the Mississippi, for there they encountered a physical environment that their forest-adjusted frontier skills could not conquer. The Great Plains province, stretching limitlessly away to the Rockies, was a giant grassland where wood for housing, fencing, and fuel was nonexistent, and where a semiarid climate defied farmers whose techniques had been developed in the humid East. So the orderly march westward halted before this barrier, while a few of the more venturesome pioneers explored the possibilities of the unknown lands that lay beyond. These were the men who formed caravans of covered wagons and during the early 1840's defied nature by moving westward over the Oregon and California trails to the fertile farm lands that awaited them in the Willamette and Sacramento valleys. Although few in numbers, they played yeomen's roles in paving the way for later comers. Oregon pioneers helped force the settlement that added that disputed land to the United States, while their counterparts in California precipitated the crisis which led Mexico to surrender its hold on all the Southwest.

The occupation of this distant land would still have proceeded at a snail's pace had not the discovery of gold in a stream cascading westward from California's Sierra Nevada Mountains launched the fabulous rush of the Forty-niners (q.v.). Most of the 100,000 gold seekers who reached the West failed to "strike it rich" and turned to farming or shopkeeping instead, forming a staple population that allowed California to win statehood in 1850. Others, hopelessly infected with the prospecting fever, streamed out of the state in their search for wealth. Wherever they went—in Nevada and Arizona, across Idaho and Montana and Wyoming, into Colorado and the

Black Hills of South Dakota—strike after strike was made, and each attracted an influx of starry-eyed miners. During the two decades after 1849 their isolated mining camps blossomed into permanent settlements as farmers flocked in to produce food and politicians courted their favor by dividing all the trans-Rocky Mountain West into states or territories.

With the eastward thrust of the mining frontier, only the Great Plains province remained largely unsettled at the close of the Civil War. This last great West could be subdued in one of two ways: either by adapting economic practices to its unique environment or by conquering that environment with man-made devices. Both methods were tried, the first by cattlemen who transformed the Great Plains into a giant pastureland between 1865 and 1887, the second by small farmers whose fenced fields, relentlessly intruding from the East, gradually drove the ranchers westward as the open range diminished. Their advance was made possible by technological developments stemming from the wave of postwar industrialism; barbed wire fences, windmills, railroads, and efficient farm machinery were the tools used in the conquest of America's last West. So effectively did they allow the westward-sweeping farmers to transform barren grasslands into fertile fields that by 1890 the director of the census could announce that "there can hardly be said to be a frontier line" remaining in the United States. One era in history had drawn to a close.

Reactions varied greatly as Americans during the next decades adjusted themselves to a closed-space existence. Some feared that dwindling resources and a mounting population would usher in an era of starvation; the president of one western railroad prophesied that "in twenty-five years we shall have a nation-wide famine." Others, such as President Theodore Roosevelt, sought to awaken the nation to the need of conserving what was left of its natural heritage. Still others, with Presidents Woodrow Wilson and Franklin Delano Roosevelt in the van, advocated a positive role on the part of the federal government as a means of providing individuals with the security and opportunity formerly offered by the open frontier. "Today," wrote Franklin Roosevelt in 1935, "we can no longer escape into virgin territory: we must master our environment."

Less spectacular, but nonetheless important, was the impact of the passing of the West on the nation's historians and social scientists. Inspired by the writings of the pioneer historian of the frontier, Frederick Jackson Turner of Wisconsin, they began an appraisal of both past and future as viewed in the light of this unique national experience. Their findings indicated that much which was typically American in both the characteristics of the people of the United States and their institutions was traceable to the three centuries of expansion which had marked their history.

This expansion, historians concluded, had led to a constant rebirth of civilization in the West. As pioneers moved into a wilderness environment they found that habits as well as artifacts acquired in regions of compact settlement were no longer essential. Complex political institutions proved only burdensome in sparsely settled western communities; economic specialization was valueless in a region where each man provided for his own needs; social status based on inherited prestige vanished in a land where the individual's contribution was judged by his skill with rifle or ax; cultural pursuits seemed outmoded in a primitive social organism where so many material tasks demanded completion. Hence practices and institutions common in the East were discarded as life reverted toward simpler forms. Thus did man in the virgin West forsake much of his heritage, and prepare himself to develop new traits and devices suited to the environment in which he found himself.

These slowly evolved as new settlers flocked in to thicken the population of each frontier community. With social controls increasingly necessary, governmental activities were expanded, economic specialization set in, society developed along familiar hierarchal lines, and cultural activities quickened. Eventually a full-blown civilization emerged, but this differed significantly from those of the East on which it was based. The impact of the environment, the accidental divergences natural in areas of separate evolution, and the contributions of representatives from many cultures present among the founders, all helped mold each western community into a social organism that was similar to, but differed from, the many that had contributed to its growth. As this process went on, over and over again for three centuries, an "Americanization" of men and their institutions took place. This transformation, obviously, was not alone responsible for the distinctive nature of civilization in the United States. That stemmed from the European heritage, the mingling of peoples from many lands, the continuing impact of ideas from abroad, the Industrial Revolution, and other forces. But those features of life and thought that are usually considered to be most typically American can be traced in some degree to the influence of the West during the nation's formative period.

This is the case with certain individual traits or characteristics. The Americans are a mobile people, loosely bound to any one place and ready to move when opportunity beckons; the typical frontiersman drifted westward so often that his allegiance to any locality could not be deeply rooted. They are an inventive people who accept innovation unquestioningly and prefer change to adaptation; their pioneer ancestors acquired this frame of mind by constantly facing new situations where past precedents did not apply. They are a materialistic people, with less time for culture than most peoples of the Western World; Westerners could pay little attention to the arts in a primitive land where the battle against nature absorbed all of their energies. They are an individualistic people, resenting any attempt by the government to interfere with their economic activities; frontiersmen lived amidst such abundance that each man could care for his own needs without the aid or intrusion of society. With the passing of the West, American individualism, materialism, and mobility began to diminish, but they remain as noticeable characteristics among many people.

Equally notable was the frontier's effect on many institutions. Economic practices in the United States are geared to the need of constantly replacing artifacts and machines that would be carefully preserved in other countries of the world, for Americans have a tendency to discard the old as soon as a new model appears. This habit they acquired from their pioneer fore-

bears who lived amidst such an abundance of natural resources that waste became second nature to them. Political institutions also bear the stamp of the nation's formative years in their emphasis on democratic practices. Democracy did not originate in the forests of the New World, of course; it was well developed in European theory and practice when the Anglo-American frontier was in its infancy. Yet conditions in the West tended to deepen faith in democratic practices. There poverty served as a great leveler; there nature emphasized the equality of men by diminishing the importance of wealth and hereditary privilege; there the urge to self-rule was strong among men who realized that Eastern legislators did not understand their unique problems. On the frontier, as nowhere else in the new land, was born a deep-seated faith in democracy that has remained a part of the national heritage. See also AMERICAN EXPANSION POLICY; UNITED STATES—*40. Founding of the Nation.*

RAY ALLEN BILLINGTON,
William Smith Mason Professor of History, Northwestern University.

WEST INDIES, the name given to the islands lying southeast of the United States, between southern Florida and northern Venezuela. The main island arc, from the Bahama Islands and Cuba in the north to Trinidad in the south, separates the Caribbean Sea from the Atlantic Ocean. Other islands, all of small size with the exception of Jamaica, lie in the Caribbean closer to the Middle and South American coasts. The islands are scattered over an area 2,000 miles from east to west and 1,500 miles from north to south, yet the total land area involved is only 91,300 square miles.

Various names are applied to certain groups of islands within the West Indies. The GREATER ANTILLES are the four larger islands, and the small ones adjacent to their shores, just south and east of Florida. From west to east, they are Cuba (44,218 square miles), Jamaica (4,411 square miles), Hispaniola (29,530 square miles), and Puerto Rico (3,435 square miles); geologically, the Virgin Islands (British and United States) also belong with this group. Defined in terms of geological origin, the LESSER ANTILLES are properly those islands stretching eastward and southward from Anegada Passage, the water opening just east of the Virgin Islands of the United States (64° west longitude). Among the principal islands in this group are the British Windward and Leeward Islands (excluding the Virgin Islands), St. Martin, Guadeloupe, Martinique, Margarita, Bonaire, Curaçao, and Aruba. In common usage, the Virgin Islands, Barbados, Trinidad, and Tobago are also included among the Lesser Antilles. Another grouping is that of the LEEWARD ISLANDS and WINDWARD ISLANDS. The British Leewards include the British Virgin Islands, Anguilla, Barbuda, St. Kitts, Nevis, Antigua, and Montserrat; in a broader sense, the Leewards are defined as comprising also the Virgin Islands of the United States, Guadeloupe, and neighboring islands, St. Eustatius, Saba, and St. Martin, although the Dutch designate the last three as Windward Islands. The British Windwards include Dominica, St. Lucia, St. Vincent, Grenada, and the Grenadines. The name is also applied in a broader sense to include the French island of Martinique. Dominica, transferred for administrative purposes to the Windwards in 1940, belongs geographically among the Leewards.

Geology.—The West Indies range in size from Cuba, which is slightly larger than the State of Ohio, to coral reefs only a few acres in extent. Some are mountainous; others lie barely above sea level. The Greater Antilles collectively have an area of 81,600 square miles, 89 per cent of the total for the West Indies. Structurally, they represent fragments of submerged mountains, to the flanks of which lowlands of various origins are attached. Extending westward from Anegada Passage, these mountain remnants form the backbone of Puerto Rico and eastern Hispaniola. On the latter island, the greatest elevation in the whole system occurs, the Cordillera Central of the Dominican Republic, which rises to 10,414 feet. There the mountain axis forks, one branch forming the northern peninsula of Haiti and the Sierra Maestra of southern Cuba, and the other the southern peninsula of Haiti and the Blue Mountains of Jamaica. Low limestone platforms fringe this mountain system, forming, for example, the main part of Cuba and most of the Bahama Islands.

The Lesser Antilles are primarily a string of volcanic cones. Two were violently active in May 1902—the Grande Soufrière on Guadeloupe and Mount Pelée on Martinique. While some cones are still considered to be growing actively, others are eroded away to low-lying remnants. Among the high or mountainous islands are western Guadeloupe (4,869 feet), Martinique (4,799 feet), Dominica (4,747 feet), St. Kitts (4,313 feet), and St. Vincent (4,075 feet). In contrast, low islands like Anguilla, Barbuda, and eastern Guadeloupe all have maximum elevations below 250 feet.

Farther south, the islands are of still different origins. In part, as in Tobago and northern Trinidad, they represent continuations of mainland mountain systems; elsewhere, as in Barbados, they represent upraised portions of the continental shelf. Throughout the West Indies, coral reefs in all stages of development add to the variety of island types.

Climate.—The West Indies have a tropical maritime climate. The principal controlling factors are the warm ocean currents of the surrounding seas and the easterly trade winds which blow all year off the Atlantic. Temperatures average between 70° and 85°F. in all months, and excessively high or low temperatures never occur. Rainfall varies considerably, depending largely on island elevation and exposure. The windward, or eastern, side of a mountainous island often receives from seven to eight times as much rain as the leeward, or western, side. Commonly, there are two rainy and two dry seasons; May through July and October through November are the rainy periods. The only adverse climatic features are hurricanes, most frequent in September and October. Originating east of the islands, these violent storms move westward and then re-

curve toward the northeast. Great damage and loss of life occur when they move directly onto an island.

Political Status.—There are three independent nations in the Greater Antilles: Cuba, and Haiti and the Dominican Republic on Hispaniola. The United States holds Puerto Rico, acquired from Spain in 1898, and part of the Virgin Islands, purchased from Denmark in 1916. Venezuela controls a few small islands near her northern coast. The remaining islands are possessions of European nations. Among the British islands are Jamaica, the Bahama Islands, the Leewards, the Windwards, Barbados, and Trinidad. French islands include part of St. Martin, St. Barthélemy, Guadeloupe, Marie Galante, and Martinique. Netherlands holdings include part of St. Martin (Sint Maarten), Saba, St. Eustatius, and the group close to the Venezuelan coast, Curaçao, Aruba, and Bonaire.

Population and Economy.—Total population of the West Indies was estimated (1955) as 17,532,000. The Greater Antilles supported 88 per cent of this number: Cuba with 5,807,000; Haiti, 3,506,000; the Dominican Republic, 2,347,000; Puerto Rico, 2,229,000; and Jamaica, 1,518,000. Despite this, the greatest density of population is on Barbados, where an essentially rural, dominantly Negro population of 225,000 is limited to an area of 166 square miles, a density of 1,355 per square mile.

Tropical crop production dominates the economy within the West Indies. Sugar, long the principal trade product of the islands, is still grown on many of them, though the main concentration is now in Cuba. Coffee, cacao, tobacco, bananas, and vegetable fibers, notably henequen and cotton, are among the common crops. Cuba has significant mineral wealth in chromium, manganese, copper, and iron. The Dutch islands, Curaçao and Aruba, are important refining and transshipment centers for Venezuelan petroleum. For history and other information, see separate articles on the individual islands and the island groups.

Bibliography.—Blanshard, Paul, *Democracy and Empire in the Caribbean* (New York 1947); Waugh, Alec, *The Sugar Islands* (New York 1949); James, Preston E., *Latin America*, rev. ed. (New York 1950); Jones, Clarence F., and Darkenwald, G. Gordon, *Economic Geography*, rev. ed. (New York 1954); *The West Indies and Caribbean Year Book* (London, New York, and Toronto, annually).

HENRY M. KENDALL,
Professor of Geography, Miami University, Oxford, Ohio.

WEST LAFAYETTE, city, Indiana, in Tippecanoe County; 60 miles northwest of Indianapolis, on the Wabash River, opposite Lafayette with which it is connected by bridge. The city is the site of Purdue University (q.v.), and nearby is located the state soldiers' home. Incorporated in 1924, West Lafayette is governed by mayor and council. Pop. (1950) 11,873.

WEST LOTHIAN (formerly LINLITHGOW), county in southeastern Scotland, bordering for about 15 miles on the Firth of Forth; area 120 square miles; capital Linlithgow. Besides being a good farming and dairying region, it has important coal, oil-shale, and iron mining industries. The county is noted for its historic sites which include prehistoric and Roman remains. The Forth Bridge unites the county with that of Fife. Pop. (1951) 88,576.

WEST MEMPHIS, city, Arkansas, in Crittenden County; altitude 210 feet; on the Mississippi River, 5 miles west of Memphis, Tenn. It is served by the Chicago, Rock Island and Pacific, the Missouri Pacific, and the St. Louis-San Francisco railroads. Situated in an agricultural region, its chief industries include the processing of cotton, cottonseed oil, and soybeans. There are also lumber mills and distilleries. First settled in 1914, West Memphis was incorporated as a community in 1929 and as a city in 1935. Government is by a board of aldermen. Pop. (1950) 9,112.

WEST MIFFLIN, borough, Pennsylvania, in Allegheny County; altitude 700 feet. It lies southeast of Pittsburgh and north of McKeesport, and is partially bounded by the Monongahela River. It is served by the Pennsylvania, the Baltimore and Ohio, the New York Central, and the Pittsburgh and West Virginia railroads; also a county municipal airport. There are many important industries which include steel and coal plants, and those turning out automobile bodies, cans, and luggage; also a General Electric atomic plant. The township of Mifflin was created in 1788; the borough of West Mifflin was incorporated in 1944. Government is by mayor and council. Pop. (1950) 17,985.

WEST MILWAUKEE, village, Wisconsin, in Milwaukee County. It comprises a suburban area just west of Milwaukee. The village was incorporated in 1906. Government is by mayor and council. Pop. (1950) 5,429.

WEST MONROE, city, Louisiana, in Ouachita Parish; altitude 75 feet; on the Ouachita River and located just west of Monroe; served by the Illinois Central and the Tremont and Gulf railroads. It lies in an agricultural area which specializes in fruit and livestock. Manufactures include cottonseed oil, paper and wood products, chemicals, clothing, and meat products. The city was incorporated in 1926. Government is by mayor and council. Pop. (1950) 10,302.

WEST NEW YORK, town, New Jersey, in Hudson County; on the Hudson River, four miles north of Jersey City. Its mile-long waterfront has docks and grain elevators. Manufactures include textiles, embroideries and clothing, radio parts, leather goods, and toys. The town was incorporated in 1898 and has a commission government. Pop. (1950) 37,683.

WEST NEWTON, borough, Pennsylvania, in Westmoreland County; altitude 770 feet; on the Youghiogheny River, 20 miles southeast of Pittsburgh; served by the Pittsburgh and Lake Erie and the Baltimore and Ohio railroads. Local industries produce metal products, lumber, and beverages. The borough was incorporated in 1842. It has a mayor and council. Pop. (1950) 3,619.

WEST ORANGE, town, New Jersey, in Essex County, altitude 190 feet; 5 miles northwest of Newark, on the Erie Railroad. It is at the base and on the slopes of Watchung Mountains. Eagle Rock (650 feet) affords a splendid view. Llewellyn Park (750 acres) has fine residences and scenery. Here Thomas A. Edison lived after 1887, and the main industries are those

connected with his laboratory—the manufacture of electrical equipment. Other manufactures are machinery, metal products, tiles and clothing. Separated from Orange in 1862 as Fairmount, the place was named West Orange in 1863, and was incorporated as a town in 1890. It has a commission government. Pop. (1950) 28,605.

WEST PALM BEACH, city, Florida, port of entry and seat of Palm Beach County; altitude 15 feet; 67 miles north of Miami; on the Florida East Coast and the Seaboard Air Line railroads; with airline service. The city is a distributing point for agricultural produce. Manufactures include air-conditioning equipment, prefabricated buildings, concrete products, and beverages. There are music, art, and garden clubs; a memorial library; a marine museum, and an alligator and ostrich farm. The city was incorporated in 1894; it has city manager government. Pop. (1950) 43,162.

WEST PATERSON, borough, New Jersey, in Passaic County; altitude 190 feet. It comprises a suburban area adjoining Paterson on the southwest; on the Passaic River and served by the Delaware, Lackawanna and Western Railroad. Primarily it is a residential community. It was incorporated in 1917 and has a mayor and council. Pop. (1950) 3,931.

WEST PITTSTON, borough, Pennsylvania, in Luzerne County; altitude 577 feet; on the Susquehanna River; opposite Pittston (q.v.); on the Delaware, Lackawanna and Western, and the Lehigh Valley railroads. It is mainly residential, but has silk mills and machine shops. It was incorporated in 1857 and has mayor and council. Pop. (1950) 7,230.

WEST PLAINS, city, Missouri, seat of Howell County, altitude 955 feet; 90 miles southeast of Springfield, on the St. Louis-San Francisco Railroad. It is an agricultural region in the Ozarks, and is a shipping center for livestock, dairy products, lumber, and grain. It was laid out in 1858 and is governed by a commission. Pop. (1950) 4,918.

WEST POINT, city, Georgia, in Troup County; altitude 580 feet; on the Chattahoochee River, 14 miles southwest of La Grange; served by the Atlanta and West Point and the Western Railway of Alabama, and Chattahoochee Valley railroads, and by federal and state highways. In the midst of a cotton-raising region, the city's chief manufactures are textiles, textile machinery, and dyes.

West Point was incorporated in 1831. During the Civil War it was a supply depot for the Confederate Army. Pop. (1950) 4,076.

WEST POINT, city, Mississippi, seat of Clay County, altitude 240 feet; 16 miles northwest of Columbus, on the Columbus and Greenville, the Gulf, Mobile and Ohio, and the Illinois Central railroads. It has food-processing plants, cottonseed oil and lumber mills, and it manufactures textiles, clothing, and farm machinery. The city has a Carnegie library and is the seat of Mary Holmes Seminary, a junior college for Negroes. West Point was incorporated in 1858 and is governed by mayor and council. Pop. (1950) 6,432.

WEST POINT, United States military post, located in Orange County, New York; altitude 167 feet, on the west bank of the Hudson River; about 50 miles north of New York City on the New York Central Railroad. The site is very picturesque. The eastern end of the point slopes abruptly to the river. On the northern side, the slope is more gradual. To the northwest are Crow's Nest and Storm King mountains, and to the south is the town of Highland Falls. The government reservation, including Constitution Island, contains about 15,000 acres. It was occupied as a military post by the Americans during the Revolutionary War and was strongly fortified. An iron chain was stretched across the river to Constitution Island to prevent British vessels from ascending. In 1780 the point was under the command of Benedict Arnold whose plan to betray it to the enemy was frustrated by the capture of Major John André. West Point was a military post after the revolution, and a military school was established there in 1794. On March 16, 1802, the United States Military Academy (q.v.) was authorized by Congress.

WEST POINT, town, Virginia, in King William County; altitude 16 feet; at the junction of three rivers, the Pamunkey, Mattaponi, and York; 38 miles east of Richmond; on the Southern Railroad. At the head of navigation on the York River, it has steamboat connections, and is a shipping point for the cotton growers of the surrounding area. Its industrial history includes oyster packing, cotton processing, and the manufacture of fertilizers from the phosphatic marl and potash deposits on the Pamunkey. There is a pulp and paper plant. Founded in colonial times, the place was named for the four West brothers: Thomas, Francis, John, and Nathaniel, of whom three were governors. In 1691 the General Assembly made the town a port of entry; in 1705, a free borough. George Washington frequently stopped here on his way between Mount Vernon and Williamsburg, and nearby is Martha Washington's birthplace. Pop. (1950) 1,919.

WEST POINT, or ELTHAM'S LANDING (Va.), **Engagement at.** When Yorktown (q.v.) was abandoned May 4, 1862, it was intended by Gen. George B. McClellan that William B. Franklin's division, followed by Sedgwick's, Porter's and Richardson's, should be moved in transports up York River to a place opposite West Point and, striking across to the main roads, cut off the retreat of such bodies of Gen. J. E. Johnston's army as might be below, making their way to New Kent Court House. But the day before the evacuation of Yorktown, Franklin had received permission to land his men, who had been on the transports several days, and it was not until the morning of May 6 that he could get them on board again. That afternoon he landed his men above West Point and sent the transports back for Gen. John Sedgwick's division. He had no instructions except to wait for orders. He encamped his division on high wooded ground, over which ran a road from the landing to Barhamsville and thence toward New Kent Court House. Franklin's presence threatened this road on which part of the Confederate Army was retreating from Yorktown and Williamsburg, and under General Johnston's orders Whiting's and Hampton's brigades had been put in position to

protect the road. On the morning of May 7, Whiting was ordered to advance and drive Franklin back to his landing place. By noon Franklin had been pushed back under cover of the gunboats. The Confederates then attempted to shell the transports in York River, but the range was too great, while the fire from the Union gunboats was effective, and compelled the Confederates to withdraw about 3 P.M., and resume their position near Barhamsville. Franklin's troops resumed their former position.

WEST POINT MILITARY ACADEMY. See UNITED STATES MILITARY ACADEMY.

WEST READING, borough, Pennsylvania, in Berks County; situated opposite Reading. On the Schuylkill River, it is served by Reading Company Railroad and a state highway. There are manufactures of fabrics, hats, hoisery, knit goods, and paper. Settled in 1748, West Reading was incorporated in 1907. It has a council-manager plan of government. Pop. (1950) 5,072.

WEST RIVER, China. See SI KIANG.

WEST RUTLAND, town, Vermont, in Rutland County; altitude 500 feet; in the valley of Otter Creek; 68 miles southeast of Burlington; served by the Delaware and Hudson; the Clarendon and Pittsford; and the Rutland railroads. It is the center of the state's marble industry, quarrying and working the stone. West Rutland was set off from the old township of Rutland in 1886. Its high school and library are built of local marble. Pop. (1950) 2,487.

WEST SAINT PAUL, city, Minnesota, in Dakota County, altitude 703 feet, west of St. Paul on a state highway; a residential suburb. Area six square miles. It has a mayor and six aldermen. Pop. (1950) 7,955.

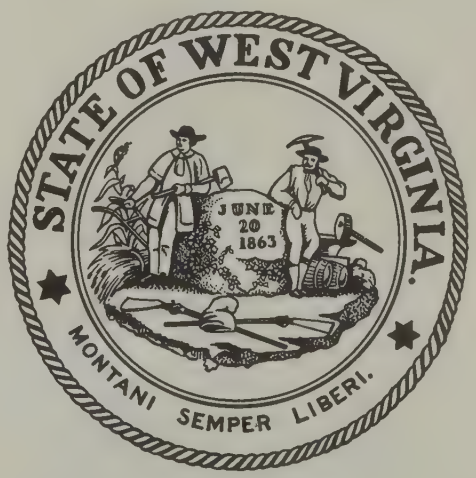
WEST SPRINGFIELD, town, Massachusetts, in Hampden County; altitude 103 feet; on the Connecticut River; on the Boston and Albany Railroad; opposite Springfield, many of whose business people have their homes here. There are several industrial establishments, among which are paper works, chemical, machine and railroad repair shops, magneto and gasoline pump manufactures, and an electric generating plant. Many of the townspeople are interested in market gardening. The Eastern States Exposition is held here. The Day House, built in 1754, is now a historical museum. Pop. (1950) 20,438.

WEST TERRE HAUTE, city, Indiana, in Vigo County, on the Wabash River, on the western outskirts of Terre Haute, on the Pennsylvania Railroad. Its industries include the working of extensive deposits of coal and clay, and there is a paving-brick plant. Pop. (1950) 3,357.

WEST VIRGINIA, one of the South Atlantic states of the United States, known as the Trans-Allegheny Region of Virginia prior to its separation from the mother state. The state is bounded on the north by Ohio, Pennsylvania, and Maryland; on the south by Virginia and Kentucky; on the east by Virginia and Maryland; and on the west by Ohio and Kentucky. The narrow strip of land at the north between Ohio and Pennsylvania is called the Northern Panhandle, and that at the east is called the Eastern Panhandle. The latter is almost entirely surrounded by Maryland and Virginia and is joined to the rest of West Virginia by a narrow neck of land only 15 miles wide.

State flag.

Because of its natural character the state boundary is perhaps the most irregular in the Union. The West Virginia-Ohio line is low water mark on the western bank of the Ohio River, thus throwing the islands within West Virginia. The center of the Big Sandy and of Tug Fork of that stream is the boundary between West Virginia and Kentucky. The Virginia-West Virginia line is made up of portions of the boundaries of border counties and generally follows the crest of meandering mountain ridges. The West Virginia-Maryland line is the south bank at low water mark of the Potomac and its North Branch to the source of the latter at Fairfax Stone, thence by a line due north about 35 miles to the Mason and Dixon line, which forms the boundary between West Virginia and Pennsylvania to its western terminus at a point about 20 miles east of the Ohio River. Thence the Pennsylvania boundary extends due north 61 miles to the northern bank of the Ohio.



State seal (obverse).

Total area (40th in national rank)	24,181 square miles
Land area	24,080 square miles
Inland water area	101 square miles
Latitude	37° 10′—40° 40′ N.
Longitude	70° 40′—82° 40′ W.
Altitude	247—4,860 feet
Population (1950)	2,005,552
Estimate, July 1, 1956	1,983,000
Capital—Charleston; population (1950)	73,501
Admitted to Union as 35th state	June 20, 1863
State bird	Cardinal
State flower (adopted Jan. 23, 1903)	Big rhododendron

State motto *Montani Semper Liberi*
(Mountaineers are always freemen)
State nicknames.."Mountain State"; "Panhandle State"; "Switzerland of America"
State song (unofficial) *West Virginia Hills*
State tree Sugar maple

State seal (reverse).

A discussion of West Virginia's geography, government, and history is presented under the following headings:

1. Physical Features and Resources
2. Population and Political Divisions
3. Government and Politics
4. Education and Social Welfare
5. Economic Activities
6. Places of Interest
7. Famous Men and Women
8. History

1. PHYSICAL FEATURES AND RESOURCES

Topography.—The average elevation above sea level of the surface of West Virginia is about 1,500 feet. The range in altitude is 4,613 feet, the lowest point being Harpers Ferry at 247 feet and the highest being the summit of Spruce Knob, Pendleton County, at 4,860 feet. The lowest point in the Mississippi Valley drainage is at Kenova (500 feet). Of the total area, over 20,635 square miles drain into the Ohio either directly or indirectly; nearly 3,500 square miles drain into the Potomac; and about 80 square miles in Monroe County drain into the James. The predominant feature of West Virginia topography is ruggedness. There are no natural lakes or pools of considerable size, and the areas of poorly drained land are few and small. The surface has been scientifically described:

". . . as an elevated, somewhat rolling plain, which has been dissected by the action of running water into an intricate system of hills and valleys. The varying degree to which this dissection has been affected, as well as differences in the underlying rocks, has resulted in the variety of topography to be seen in the State. This ranges from a slightly rolling plateau, intersected by the narrow, steep-walled valleys of scattered, swift, steeply descending streams; through regions in which the original plateau has been dissected into a series of flat-topped hills and ridges separated by narrow valleys; to a stage in which the hills are no longer flat-topped but sharply crested, while the valleys have grown wider, and the streams assumed meandering courses." (Price, Tucker, and Haught, *Geology and Natural Resources of West Virginia,* p. 13).

To the west of a somewhat irregular line called "Allegheny Front," passing from Keyser to Bluefield through Green Bank and White Sulphur Springs, the beds of rock in which the valleys have been carved lie practically horizontal. As the valleys extend in general southeast and northwest directions, they are not therefore related to these beds of rock which extend from northeast to southwest. In other words, the streams have, through countless ages, worn their beds through the Allegheny Highland of about 6,000 square miles, the Cumberland Plateau of about 6,500 square miles, and the Ohio Valley region proper of about 8,000 square miles, at respective mean elevations of about 4,000 to 2,000, 2,000 to 1,000, and 1,000 to 500 feet. East of this drainage system (the dendritic) the folds of the elevations are much sharper and control to a great extent the courses of the valleys. Here the parallel courses of the main streams contrast strongly with the irregular courses of streams in the Trans-Allegheny area, particularly in the Cumberland Plateau where they are featured by numerous rapids. Regardless of the great differences in these two drainage systems, each has its origin in a common center in the northern portion of Pocahontas County. Here are the sources of the South Branch of the Potomac, Gauley, Elk, Cheat, Greenbrier, and Tygart rivers.

In recent years the drainage system has been modified somewhat by the use of locks and dams and artificial reservoirs. Through use of the former the Ohio has a nine-foot stage throughout its entire course and the Kanawha from its mouth to the falls about 40 miles east of Charleston. Lake Lynn, otherwise known as "Cheat Lake," on Cheat River, is used primarily for power; Tygart River Reservoir near Grafton is used primarily for flood control; and Bluestone Reservoir on New River near the mouth of the Greenbrier is for a similar purpose. Still other reservoirs are being projected with a view to eliminating flood menaces.

Climate.—Because of the range in altitude, which is equivalent to about 10 to 15 degrees of latitude, West Virginia has a great diversity of climate. As only the Eastern Panhandle is affected perceptibly by the Atlantic Ocean, the climate of the major part of the state is decidedly continental and thus subject to great and frequent changes in temperature. The mean annual temperature ranges from 56°F. in the southwestern counties to 48° in the mountain counties. For the greater part of the state the mean annual temperature is between 52° and 53°F., and the range is from —15° to 100°F., but temperatures as low as —35° and as high as 107°F. have been recorded. In the low counties the growing season is about six months and in the highest about five months. The prevailing winds are from the southwest. The annual precipitation varies from well over 50 inches in a few of the highest counties to 35 and 40 inches in counties of the panhandles. The mean for the greater part of the state is between 45 and 50 inches and is usually fairly evenly distributed, but some seasons are very dry.

Natural Resources.—*Plant Life.*—Before the first white settlers came, present West Virginia was almost completely covered by a mixed hardwood growth known to botanists as the "Appalachian Hardwood Forest." About 1800 it was visited by André Michaux (from France) and other botanists who generally agreed that this forest was then richer than that which had covered China five to six thousand years before. Among the growths which they found that were unknown to either modern Europe or China were tulip or "poplar," locust, hickory, ash, oak, maple, walnut, beech, chestnut, cherry, sycamore, elm, birch and mulberry. These and other growths, including about 130 varieties, grow in West Virginia, which 30 years ago contained more different

◉ County Seat

kinds of hardwood than any other state in the United States. In the year 1953, West Virginia forests yielded approximately 382 million board feet of lumber, largely hardwood. Some idea of the primeval forest of West Virginia may be had from the Mingo Oak, located near the Mingo-Logan county line. At the time of its death in 1938 this tree was said to be the largest and the oldest living thing in the state. It was about 600 years old and had attained a height of 145 feet and a circumference of 30 feet and 9 inches.

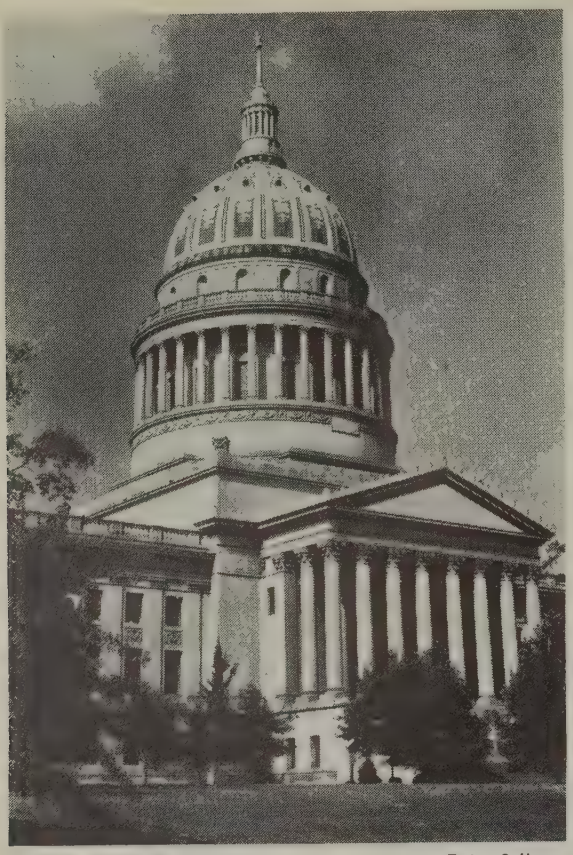
Because of the greed of the "lumber kings" and the absence of a conservation policy, very little of the virgin forest is now standing. Meanwhile blights, rusts, and insects took their toll. Consequently the chestnut and certain kinds of pines are all but gone. Until recently little was done toward reforesting the cutover and waste timber lands. Much is now being done to that end in both the state and the national forests. In 1949 the maple was adopted as the state tree. The oaks, the elm, and the walnut are also favorites.

Because of its abundant plant life, West Virginia is a botanist's paradise. Among rare plants are coltsfoot, sundew, and bog rosemary. Because of the varied climate and wide drainage system, the more common plants include many of those found in Canada and in the subtropical areas of the Appalachian Highlands. Among favorite shrubs are azalea (wild honeysuckle), rhododendron (big laurel), kalmia (laurel), and the American wisteria. Box huckleberry may be older than the Mingo Oak, and a lone hawthorn tree in the Cranberry Glades of Pocahontas County has attained a height of 40 feet.

Animal Life.—Animal remains found here and there indicate that West Virginia was once inhabited by many kinds of huge, clumsy sloth-like animals. They indicate also that the climate has at times been much colder and at other times much hotter than at present. Otherwise neither the musk ox nor the peccary, former inhabitants, could have lived here. The first white settlers found deer, wolves, bears, pumas, beaver, and elk in large numbers, and there were a few buffalo in the Kanawha Valley. Except protected deer, these animals are now almost extinct, but smaller animals, such as foxes, skunks, raccoons, and opossums, are tending to increase in numbers, and beavers are being rehabilitated and trapped under regulations.

In recent years wastes from mines and sawmills have destroyed most of the game fish, but, through restockings, many streams still contain bass, trout, and pike of several varieties. There are several kinds of frogs, toads, waterdogs, turtles, and snakes, but only two species of snakes, rattlers and copperheads, are poisonous. There are about 300 species and subspecies of birds, and in 1949 the cardinal became the state bird. The robin, the wren, and the tanager are favorites.

Much is being done to conserve fish and game



Ewing Galloway

The State Capitol at Charleston.

life through the use of hatcheries and refuges. Of the former the state conservation commission maintains five: Ridge Bass Hatchery of 31.30 acres in Morgan County; Palestine Bass Hatchery of 127.40 acres in Wirt County; Marlinton Trout Hatchery of 28.612 acres in Pocahontas County; Petersburg Trout Hatchery of 9 acres in Grant County; and Spring Run of 41.03 acres in Grant County. In addition, there are two federal hatcheries, one at White Sulphur Springs and one at Leetown. There are also six game refuges: State Game Farm, of 329.85 acres in Upshur County; Hornor, of 189 acres in Lewis County; Elk River, of 6,908.78 acres in Braxton County; Nathaniel Mountain, of 8,876 acres in Hampshire County; Short Mountain, 7,754 acres in Hampshire County; and Bear Rock Lakes, of 173.18 acres in Ohio County.

Minerals.—Coal, a carbonaceous substance formed from vegetable remains, first as peat, then as lignite, and then as bitumen, is found in large quantities in the last named stage, but there is little in the still more final form of anthracite. There are 17,280 square miles of coal area, and the total minable acreage, including all seams, is 24,015,381. West Virginia ranks first among the states in bituminous coal production.

West Virginia also ranks high in the production of oil and gas and their byproducts. Other minerals found include salt brine and rock salt, which are widely distributed west of the Alleghenies. The former is now used extensively in the Kanawha Valley for the manufacture of a variety of products. Among still other minerals are barite, found in Mercer County and used in making white lead; bromine, found in Mason County and used as a medicine, and in the synthetic chemical and color industries; celestite, found on the western slope of Knobly Mountain and used in making fireworks and in medicine; various cement materials used in construction works; clays (brick, fire, and stoneware); dolomite, found in the Eastern Panhandle and in Monroe County, used as a substitute for limestone; fluorspar, found in Jefferson County, used in the manufacture of chemicals, preservatives, and opalescent glass; grahamite; gravel; grindstone; hematite, both red and fossil; limestone; niter (saltpeter); ocher; Devonian black shale; sand (building, glass, and molding); shale; and siderite. The state is famous for its mineral springs, those at White Sulphur and Berkeley Springs (formerly Bath) being widely known. See also sect. *5. Economic Activities.*

Soils.—From the northeast corner of the state, extending south and southwest to the Big Sandy River, the country is mountainous, with narrow valleys. The soil is generally fertile and the land productive. Clay soil is found in some of the higher sections, alluvial soil in the upland valleys, and sandy soils in the northeast. In the extreme northeastern counties the soil is of rich limestone. The surface near the Ohio River is gently rolling and there, too, the soil is rich.

2. POPULATION AND POLITICAL DIVISIONS

In 1950, the population was 2,005,552, as compared with 1,901,947 in 1940. Of the 1950 total, 114,867 were Negroes, McDowell County having the largest number. Other counties with large Negro populations were Kanawha, Fayette, Raleigh, Mercer, Logan, Mingo, Jefferson, and Ohio. Among the foreign-born white residents (34,586), Italians (8,557) outnumbered all others. The next largest numbers, in the order named, were Poles, English, Hungarians, Germans, Greeks, Yugoslavians, Czechoslovakians, Austrians, and Russians. Of the state's 55 counties, 49 gained in population between 1930 and 1940, but only 27 between 1940 and 1950. All but two of the counties losing population between 1940 and 1950 were predominantly rural, and 19 had no urban population at all. In 1950, West Virginia's 214 incorporated places comprised 60 cities, 149 towns, and 5 villages.

The Capital City.—The present capital, Charleston, with a population of 73,501 (1950), has not always been the seat of government. From June 20, 1863, to April 1, 1870, and again from May 23, 1875, to May 1, 1885, it was Wheeling. As the removals were made by steamboat, the seat of government was frequently described as the "Capital on Wheels." Because of the several removals, and the fire of Jan. 3, 1921, there have been several capitol buildings. The present one, as designed by Cass Gilbert and dedicated on June 20, 1932, is one of the most beautiful in the United States.

Other Cities.—In the order of their population (1950) the other leading cities are Huntington (86,353), Wheeling (58,891), Clarksburg (32,014), Parkersburg (29,684), Fairmont (29,346), Morgantown (25,525), Weirton (24,005), Bluefield (21,506), Beckley (19,397), South Charleston (16,686), Martinsburg (15,621), and Moundsville (14,772). South Parkersburg (10,808) is the state's largest unincorporated place. (For populations of other places, see back of state map.)

Reversing a consistent trend from 1870 to 1930, the percentage of the state's urban population de-

clined from 28.4 in 1930 to 28.1 in 1940, owing largely to populational movements into suburban areas. However, the urbanization of population resumed in the 1940's, and in 1950 urban residents numbering 694,487 represented 34.6 per cent of the total population.

Counties.—The counties of the state, with their respective seats of government, are:

COUNTY	COUNTY SEAT	COUNTY	COUNTY SEAT
Barbour	Philippi	Mineral	Keyser
Berkeley	Martinsburg	Mingo	Williamson
Boone	Madison	Monongalia	Morgantown
Braxton	Sutton	Monroe	Union
Brooke	Wellsburg	Morgan	Berkeley Springs
Cabell	Huntington	Nicholas	Summersville
Calhoun	Grantsville	Ohio	Wheeling
Clay	Clay	Pendleton	Franklin
Doddridge	West Union	Pleasants	St. Mary's
Fayette	Fayetteville	Pocahontas	Marlinton
Gilmer	Glenville	Preston	Kingwood
Grant	Petersburg	Putnam	Winfield
Greenbrier	Lewisburg	Raleigh	Beckley
Hampshire	Romney	Randolph	Elkins
Hancock	New Cumberland	Ritchie	Harrisville
Hardy	Moorefield	Roane	Spencer
Harrison	Clarksburg	Summers	Hinton
Jackson	Ripley	Taylor	Grafton
Jefferson	Charles Town	Tucker	Parsons
Kanawha	Charleston	Tyler	Middlebourne
Lewis	Weston	Upshur	Buckhannon
Lincoln	Hamlin	Wayne	Wayne
Logan	Logan	Webster	Webster Springs
McDowell	Welch	Wetzel	New Martinsville
Marion	Fairmont	Wirt	Elizabeth
Marshall	Moundsville	Wood	Parkersburg
Mason	Point Pleasant	Wyoming	Pineville
Mercer	Princeton		

3. GOVERNMENT AND POLITICS

State Constitution.—The present constitution went into effect in 1872. Amendments must be passed by a two-thirds vote of the legislature and ratified by a majority of voters voting on an amendment at election.

Executive.—The executive branch of the government consists of a governor, secretary of state, superintendent of schools, treasurer, auditor, attorney general, and commissioner of agriculture, all of which positions are elective. The governor is elected for a term of four years and may not serve more than one consecutive term. He is invested with the power of the veto, may convene a special session of legislature, and make appointments with the approval of the Senate.

GOVERNORS

Arthur I. Boreman	Republican	1863–1869
Daniel D. T. Farnsworth[1]	"	1869
William E. Stevenson	"	1869–1871
John J. Jacob	Democrat	1871–1877
Henry M. Mathews	"	1877–1881
Jacob B. Jackson	"	1881–1885
E. Willis Wilson[2]	"	1885–1890
A. Brooks Fleming	"	1890–1893
William A. MacCorkle	"	1893–1897
George W. Atkinson	Republican	1897–1901
Albert B. White	"	1901–1905
William M. O. Dawson	"	1905–1909
William E. Glasscock	"	1909–1913
Henry D. Hatfield	"	1913–1917
John J. Cornwell	Democrat	1917–1921
Ephraim F. Morgan	Republican	1921–1925
Howard M. Gore	"	1925–1929
William G. Conley	"	1929–1933
H. Guy Kump	Democrat	1933–1937
Homer A. Holt	"	1937–1941
M. Mansfield Neely	"	1941–1945
Clarence W. Meadows	"	1945–1949
Okey L. Patteson	"	1949–1953
William C. Marland	"	1953–1957
Cecil H. Underwood	Republican	1957–

[1] As president of the Senate, Farnsworth became governor and filled the unexpired term of Boreman who resigned to become a United States senator.

[2] The election of Governor Fleming was contested, and Governor Wilson served until the contest was determined by the legislature.

In the event of a vacancy before the expiration of the first three years of the term, a new election is held; otherwise, the president of the Senate acts as governor in the event of death, disqualification, resignation, or removal from office.

Republicans administered the state from 1863 to 1871. Without interruption but sometimes by close contests, as in 1888, the Democrats administered it from 1871 to 1897. From 1897 to 1933, Republicans were in complete control, except during 1917–1921 when John J. Cornwell was governor. In 1911 the Republicans lost each of the United States senatorships. Since 1933 the Democrats have been in control, but they lost a United States senatorship to the Republicans in 1942. The Republicans elected the governor, state superintendent of free schools, and a United States senator in 1956.

Legislative.—There are six congressional districts. The state legislature, which convenes annually on the second Wednesday of January (for a possible 60-day session in the odd years and a possible 30-day session in the even years) is composed of 32 senators and 100 delegates. For the purpose of choosing senators the state is divided into 16 districts, each of which elects one senator every two years for a term of four years. Delegates, the number from each county determined by population, are elected by counties for two-year terms, each county having at least one delegate, and one county, Kanawha, having eleven.

Judicial.—West Virginia is a part of the fourth circuit of the United States Circuit Court of Appeals and is divided into two districts (northern and southern) which are served by three judges. The state is divided into 24 judicial circuits which are served by 25 judges, the first circuit composed of Ohio, Brooke, and Hancock counties, having two judges. Cabell, Harrison, Kanawha, Marion, Mercer, McDowell, Ohio, and Raleigh counties have intermediate or criminal courts, each served by one judge, and all of the important cities have police courts.

Local Government.—West Virginia towns and cities determine their own forms of government from a number of legislature-prescribed systems. A few of them are mayor-council governed but most of them function under city managers. Local government is of county-township form with increasing emphasis upon the county. This was notably true after 1933 with the adoption of the county unit for the administration of the public free schools.

Taxation.—Tax revenue of $145,364,245 in the 1955–1956 fiscal year included $75,811,775 from a general sales tax (1 per cent on purchases from 6 to 50 cents; 2 per cent on those from 51 cents to $1) and selective sales and gross receipts taxes, and $18,343,352 from licensing. The state does not impose individual or corporate income taxes but does levy a $2 poll tax per male person.

Suffrage and Elections.—The suffrage is extended in general to all citizens who have attained the age of 21 years. Special classes of persons barred from the exercise of voting rights include paupers, people of unsound mind, and those under conviction of treason, felony, or bribery in an election. Residence within the state for one year and within the county for 60 days next preceding the election is required. A permanent voter registration law is in operation, and voters must be properly registered in order to cast their ballots.

Under this law in 1956, 702,062 Democrats and 450,320 Republicans were registered. General elections are held on the Tuesday after the first Monday in November in every even-numbered year. Closed primary elections for the nomination of state and national candidates and the selection of delegates to the national party conventions are held in the month of May in presidential election years, and in August in the nonpresidential election years.

The Greenbrier

The Greenbrier, White Sulphur Springs. A plaque in the foreground is in memory of an older and equally famous hotel of the same name which stood on this spot from 1858 to 1921.

4. EDUCATION AND SOCIAL WELFARE

Elementary and Secondary Education.—Education is free to all persons between the ages of 6 and 20 and compulsory for all those between the ages of 7 and 16.

Largely as an emergency measure all the magisterial and independent districts were abolished in 1933 and merged into 55 county units for the administration of both the elementary and the secondary schools, but the new system worked so well that there is no present desire to change it. Each county is controlled by a single board which functions through a county superintendent and his assistants. There are no independent city systems. Outstanding among the secondary schools are Linsly Military Institute, Wheeling; DeSales Heights Visitation Academy, Parkersburg; and Mount De Chantal Academy, Wheeling. The state maintains schools of elementary and secondary grade at Romney for deaf and blind children.

Higher Education.—Primarily for the training of teachers, the state maintains seven colleges: Bluefield State; Concord, at Athens; Fairmont State; Glenville State; Marshall, at Huntington; Shepherd, at Shepherdstown; and West Liberty State. The state also maintains four other institutions: West Virginia University, Morgantown; West Virginia State Institute; Potomac State College of West Virginia University (a junior college at Keyser); and West Virginia Institute of Technology, Montgomery. There are eight private and denominational colleges, namely: Alderson-Broaddus, Philippi; Bethany, Bethany; Davis and Elkins, Elkins; Mason College of Music and Fine Arts, Charleston; Morris Harvey, Charleston; Salem, Salem; Wheeling, Wheeling; and West Virginia Wesleyan, Buckhannon. There are also three junior colleges: Beckley, Beckley; Greenbrier, Lewisburg; and Greenbrier Military, Lewisburg. There are 14 business colleges—3 of them in Huntington. In 1956 there were 18 accredited schools of nursing, most of them in hospitals.

Libraries.—Public libraries, in most cases tax-supported, operate in 44 of the state's 55 counties. These institutions possess collectively more than 762,000 bound volumes, and attain an annual circulation of more than 2 million volumes. In the state capitol at Charleston the Department of Archives and History maintains an extensive library collection which features files of public records, official reports of state departments and officials, newspapers, and other materials bearing upon the history and development of the state. There are also within the state 20 college libraries, headed by that of West Virginia University, which affords more than 300,000 volumes and possesses numerous valuable manuscript and archival collections. In some of the libraries, both public and college, small museums are maintained in conjunction with the library collection. The largest and most important of these is operated by the Department of Archives and History in the state capitol.

Public Welfare.—State charitable institutions include the Children's Home at Elkins for whites and the Industrial Home for Colored Girls at Huntington; hospitals for the mentally handicapped at Barboursville, Huntington, Lakin, Spencer, and Weston; and four state-maintained hospitals for tuberculars. There are also four industrial schools: two for whites and two for Negroes. Adult delinquents are housed in the State Penitentiary at Moundsville and in the Medium Security Prison at Huttonsville; there is also a State Prison for Women at Pence Springs. All executions under the capital punishment law take place in the state penitentiary. White Sulphur Springs was an army hospital during World War II, as was also Newton D. Baker Hospital in Martinsburg. Veterans Administration hospitals are located at Beckley, Clarksburg, Huntington, and Martinsburg. A United Mine Workers of America Memorial Hospital is located at Beckley.

Public Safety.—Since 1919 West Virginia has maintained a Department of Public Safety invested with statewide police powers of a general nature. Although it is concerned with general law enforcement and the identification and apprehension of criminals, the department assumes as its primary responsibility the patroling of the state highways and the enforcement of the traffic laws. Detachments are located in every county of the state, and officers of the department cooperate with local law enforcement agencies. In addition to its other duties the department operates a State Police Academy, a Bureau of Criminal Identification and a network of 14 radio stations. There is, in addition to the Department of Public Safety, a National Guard under command of the governor in time of peace, available for use in the event of a major disaster, serious rioting, or other disturbance too extensive to be handled by the ordinary police agencies.

Social Agencies.—State social agencies cooperating with the general program of the United States Department of Health, Education, and

Ewing Galloway

The Potomac and Shenandoah rivers meet at Harpers Ferry, scene of John Brown's famous raid. On the left is Maryland; Virginia is on the right.

Welfare include a Department of Public Assistance, a Department of Employment Security, and a Division of Vocational Rehabilitation. A Department of Labor is the enforcement agency for all labor legislation except that pertaining to mines and mining. The latter is the province of a separate Department of Mines, which also directs training in mine rescue work.

Matters pertaining to sanitation, immunization, sewage disposal, and water supply are controlled by a Department of Health, and in 1957 a new Department of Mental Health was provided to supervise the state's five mental hospitals and to implement a research and training program in the field of mental health.

A State Conservation Commission directs the maintenance and development of state forests, the protection of wild life, and the general beautification of the state. There is also a State Water Commission which concerns itself with the causes of stream pollution and their abatement.

Other social agencies are a Bureau of Negro Welfare which collects statistics on all matters pertaining to the Negro citizens of the state and endeavors to facilitate harmonious relations between the races, and a Department of Veterans Affairs whose primary purpose is to furnish aid and counsel to veterans and to the widows and orphans of deceased veterans.

5. ECONOMIC ACTIVITIES

The economic activities of the people of West Virginia are widely diversified, but manufacturing, commerce, and mining furnish the major portion of the state income. General manufacturing activities, with chemical production and the fabrication of metal products heading the list, supply approximately 22 per cent of the state's income. Trade, commerce, and service activities supply another 22 per cent of the total income, while mining, which in 1956 produced more than 137 million tons of bituminous coal, is productive of an additional 17 per cent.

Farming, although widely practiced, is no longer an important source of income, the net return from agricultural activities constituting in fact only 3 per cent of the state total. Forest industries are still important; nearly 10 million acres of commercial forest lands are located within the state.

Although in earlier times the economy of the state was based almost exclusively upon coal mining, forestry, and petroleum, the trend since 1940 has been toward economic diversification. In keeping with this trend some portions of the state, particularly the Ohio and Kanawha valleys, have experienced extensive industrial development and are today the seats of important chemical and metal industries.

The state possesses many advantages of natural resources, transportation, and location in proximity to large market areas which will undoubtedly result in a continuation of the process of industrialization. Despite these favorable fac-

tors and the progress already made, per capita income lags somewhat below the national figure, having been only $1,257 in 1952.

Manufacturing Industries.—The largest industrial groups are, by value of production: chemicals and allied products; iron and steel products; stone, clay, and glass products; food and kindred products; petroleum and coal products; fabricated metals; electrical machinery; lumber and timber products; and apparel. Many new plants were added during World War II making salt, chlorine, caustic soda, bromine, ammonia, and synthetic rubber.

MAJOR MANUFACTURES, 1955

	Persons engaged	Payroll and profit income (millions of dollars)	Value of output
Chemicals	25,000	$236	$ 665
Primary metals	27,000	250	585
Stone-clay-glass products	27,000	174	286
Food products	8,000	36	182
Petroleum and coal products	3,000	26	164
Fabricated metals	11,000	33	101
Electrical machinery	6,000	29	66
Lumber	10,000	20	64
Paper and pulp	2,000	10	48
Apparel	5,000	11	41
All manufactures	146,000	889	2,375

[1] Source: *Manufacturers' Record,* 1956 blue book directory edition.

Banking.—On June 30, 1956, there were 105 state banks with combined assets of $579,509,018.24, and deposits totaling $437,716,552.68. At this same date, there were 76 national banks with total assets of $659,491,000, and deposits totaling $601,868,000.

Finances.—Following is a statement of finances for the fiscal year 1955–1956:

Balance in treasury, beginning of fiscal year 1955–1956	$ 44,440,522.71
Receipts, all sources, 1955–1956	361,800,585.95
Total	$406,241,108.66
Disbursements, 1955–1956	356,833,759.24
Balance beginning of fiscal year 1956–1957	$ 49,407,349.42

The total state indebtedness on June 30, 1956, was $135,212,000.

Transportation.—West Virginia is traversed in general easterly and westerly directions by three trunk-line railroads: the Baltimore and Ohio, the Chesapeake and Ohio, and the Norfolk and Western. Among other important railroads having access to the state are the Western Maryland, the New York Central, and the Virginian. In 1955, there were 21 railroads with 3,713 track miles. Highways, state and federal, aggregated 36,053 miles, of which 11,720 miles were improved. Including state, municipal, commercial, private, auxiliary, and emergency, West Virginia contains 43 land airports and 6 seaplane bases. Since the completion in 1929 of the nine-foot stage in the Ohio, and the later completion of that in the Kanawha, these rivers have become increasingly important in the transportation of heavy freight, mainly coal and fabricated steel.

Communications.—Communications media included (1955) 43 AM and 11 FM radio stations; 7 television stations; (1956) 30 daily newspapers (circulation, 499,430); and (Jan. 1, 1956) 110,200 business and 323,000 residential telephones.

6. PLACES OF INTEREST

Forests and Parks.—In 1955 the forests, together with their respective locations and acreage, were Seneca, Pocahontas County, 11,049 acres; Cabwaylingo, Wayne County, 6,321 acres; Kumbrabow, Randolph County, 9,424 acres; Greenbrier, Greenbrier County, 5,004 acres; Cooper's Rock, Monongalia and Preston counties, 13,348 acres; Kanawha, Kanawha County, 6,705 acres; Calvin Price, Pocahontas County, 10,776 acres; Camp Creek, Mercer County, 5,580 acres; Sleepy Creek, Morgan and Berkeley counties, 21,114 acres; and Panther Creek, McDowell County, 7,724 acres. At the same time the state parks, together with their location and acreage, were Audra Tract, Barbour County, 316 acres; Babcock, Fayette County, 3,227 acres; Blackwater Falls, Tucker County, 911 acres; Bluestone, Summers County, 278 acres; Booker T. Washington, Kanawha County, 7 acres; Cacapon, Morgan County, 5,814 acres; Carnifex Ferry Battlefield, Nicholas County, 156 acres; Cathedral, Preston County, 126 acres; Cedar Creek, Gilmer County, 2,037 acres; Droop Mountain Battlefield, Pocahontas County, 269 acres; Grand View, Raleigh County, 878 acres; Hawks Nest, Fayette County, 94 acres; Holly River, Webster County, 7,592 acres; Lost River, Hardy County, 3,841 acres; Mont Chateau, Monongalia County, 42 acres; North Bend, Ritchie County, 1,369 acres; Pinnacle Rock, Mercer County, 33 acres; Tomlinson Run, Hancock County, 1,387 acres; Tygart River State Park, Taylor and Barbour counties, 1,803 acres; Watoga, Pocahontas County, 10,057 acres; Watters Smith Memorial, Harrison County, 270 acres.

Monongahela National Forest, comprising parts of nine counties (Grant, Greenbrier, Nicholas, Pendleton, Pocahontas, Preston, Randolph, Tucker, and Webster), lies almost entirely within West Virginia. In 1956 it contained 806,139 acres and 580,036 additional acres within the Monongahela purchase boundary area had been designated for possible inclusion. At the same time 97,419 acres of the George Washington (Shenandoah) National Forest were in West Virginia and about 63,817 additional acres had been designated for possible inclusion. It comprised parts of Hampshire, Hardy, and Pendleton counties.

Other Points of Interest.—Blennerhassett Island, in the Ohio River just south of Parkersburg, is interesting historically. Here was the home of Harman Blennerhassett (q.v.), a wealthy Englishman who had come to America to pursue his interests in the natural sciences without family interference. In 1805, Aaron Burr persuaded him to join in schemes, the nature of which he seems not to have understood. As a consequence, Blennerhassett lost his home and fortune.

Two towns of West Virginia became renowned through John Brown, the antislavery leader from Kansas. His raid upon Harpers Ferry in 1859 resulted in the death of several men, and his capture. He was tried, sentenced, and hanged in Charles Town (then Charlestown, Va.).

Moundsville, in Marshall County, contains Grave Creek Mound, the largest conical burying mound known to exist in this country. The excavated interior, thought to be 3,000 years old, is open to visitors.

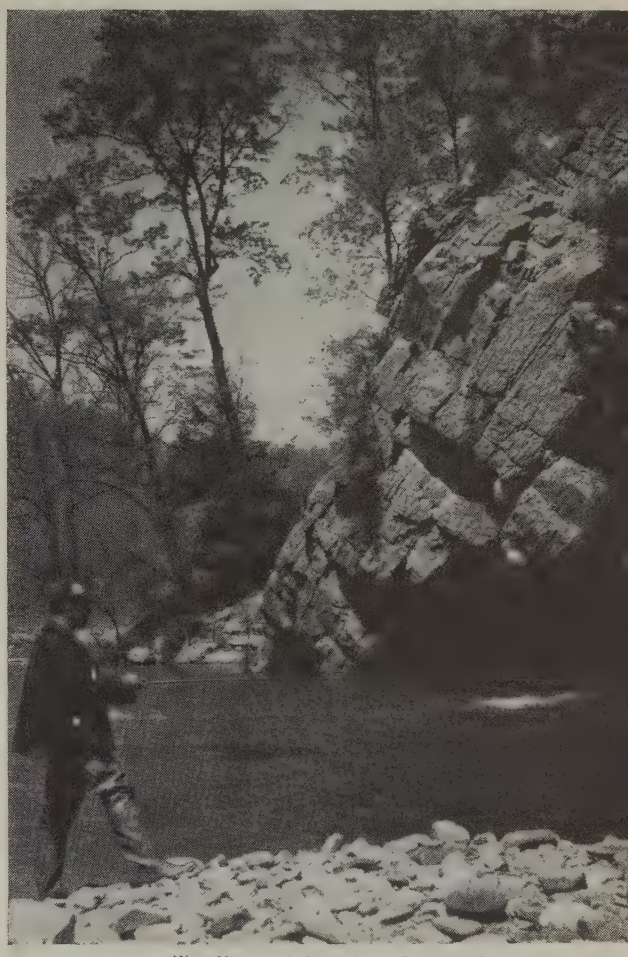
7. FAMOUS MEN AND WOMEN

Among those who have attained fame and were born in the state, or in sections of Virginia which are now a part of West Virginia, are: Ebenezer Zane (Hardy County, 1747–1812), pio-

neer; Thomas Worthington (Charles Town, 1773–1827), governor of Ohio; Robert Lucas (Shepherdstown, 1781–1853), territorial governor of Iowa; John Miller (Berkeley County, 1781–1846), congressman and governor of Missouri; Charles Bent (Charleston, 1799–1847), frontiersman; William Gregg (Monongalia County, now W. Va., 1800–1867), cotton manufacturer; David Waldo (Clarksburg, 1802–1878), physician and banker; Waitman Thomas Willey (Monongalia County, now W. Va., 1811–1900), United States senator; Martin Robinson Delany (Charles Town, 1812–1885), first Negro major in the United States Army; Philip Pendleton Cooke (Martinsburg, 1816–1850), poet and story-writer; David Hunter Strother (Martinsburg, 1816–1888), soldier, author, and illustrator; Edmund Burke Fairfield (Parkersburg, 1821–1904), educator; Jesse Lee Reno (Wheeling, 1823–1862), soldier; Thomas Jonathan Jackson (Clarksburg, 1824–1863), Confederate soldier, best remembered as "Stonewall" Jackson; John Caldwell Tidball (Ohio County, 1825–1906), soldier; William Lukens Elkins (near Wheeling, 1832–1903), capitalist; Daniel Bedinger Lucas (near Charles Town, 1836–1909), author, known as "poet of the Shenandoah Valley"; Henry Kyd Douglas (near Harpers Ferry, 1838–1903), lawyer and soldier; John Fletcher Lacey (near New Martinsville, 1841–1913), soldier and congressman; Charles Erastus Vawter (Monroe County, 1841–1905), educator; Ehrman Syme Nadal (Greenbrier County, 1843–1922), author; William Lyne Wilson (1843–1900), educator, cabinet member, congressional representative; French Ensor Chadwick (Morgantown, 1844–1919), naval officer; David Hummell Greer (Wheeling, 1844–1919), bishop; Franklin Reuben Carpenter (Parkersburg, 1848–1910), mining engineer; Lloyd Lowndes (Clarksburg, 1845–1905), governor of Maryland; Israel Charles White (Monongalia County, now W. Va., 1848–1927), geologist; Christopher Harrison Payne (near Red Sulphur Springs, 1848–1925), Negro clergyman, lawyer, federal official; William Dixon (Ohio County, 1850–1913), frontiersman, known as "Billy" Dixon; Charles Wells Russell (Wheeling, 1856–1927), lawyer, diplomat, and government official; Jonathan Prentiss Dolliver (near Kingwood, 1858–1910), statesman; George Burman Foster (Alderson, 1858–1918), clergyman; Michael Joseph Owens (Mason County, 1859–1923), inventor and glass manufacturer; Melville Davisson Post (near Clarksburg, 1871–1930), novelist and lawyer; Dwight Whitney Morrow (Huntington, 1873–1931), lawyer, banker, and diplomat; John Barton Payne (Taylor County, 1855–1935), lawyer, cabinet member, Red Cross official; Johnson N. Camden (Lewis County, 1828–1908), industrialist and United States senator; Hubert Skidmore (Webster County, 1909–1946), novelist; Harley M. Kilgore (Harrison County, 1893–1956), United States senator; Margaret Preston Montague (Greenbrier County, 1873–1955), novelist; Newton D. Baker (Berkeley County, 1871–1937), lawyer, mayor, cabinet member; and John W. Davis (Harrison County, 1873–1955), lawyer and diplomat.

8. HISTORY

The pioneer history of present West Virginia is replete with stories of personal adventure and daring. Outstanding among the participants was George Washington, who first crossed the Alleghenies in 1753. In the quest for lands and adventure which he and Christopher Gist initiated, countless thousands came and went. Among them were Daniel Boone, Lewis Wetzel, Jesse Hughes, Daniel and Levi Morgan, and the Poe brothers, Adam and Andrew. But more important than any of these were those who came to establish homes, to build churches and schools, and to record the history of the new society. One recalls Morgan



West Virginia Industrial and Publicity Commission

Trout fishing in the south branch of the Potomac River near Petersburg.

Morgan, the reputed first settler; Bishop Francis Asbury, the itinerant founder of the Methodists; and the Rev. Joseph Doddridge, author of *Notes on the Settlement and Indian Wars* (1824); and Alexander Scott Withers, author of *Chronicles of Border Warfare* (1831). For all such the Battle of Fallen Timbers (1794), the purchase of Louisiana (1803), and the coming of the steamboat (1811) were events of major importance.

During the evolution of the Jacksonian program of democracy and expansion, the interests of present West Virginia were largely political and economic. Located at the crossroads of the United States and favored by boundless resources, the area was chiefly concerned, after the War of 1812, with banks, internal improvements, and industry. When these, particularly the banks, and the internal improvements, were not provided by the federal government, the local inhabitants generally sought to increase their influence in the Virginia state government as a

means of providing them. To this end they demanded white manhood suffrage, equal representation in the General Assembly for equal numbers of white residents, and reforms in the local government. Finally, most of these demands were conceded in the reform convention of 1850.

Following 1851 the chief differences between eastern and western Virginia were economic. Although representation in the General Assembly was still arbitrarily apportioned, the question of reapportionment on the basis of white population was, under a constitutional requirement, to be submitted to the voters in 1865, and the westerners felt confident of its approval. But they had paid a high price for the concessions of the east, made in 1851. Among other things, that section demanded and secured a property classification under which Negro slaves under 12 years of age were exempt from taxation and those over that age, however valuable, could not be valued in excess of $300. Moreover, through their control of the General Assembly, the easterners had appropriated unto themselves all the state institutions and a fairly adequate system of railroads, financed in part by the state, whereas the westerners were given only macadam and dirt roads and two asylums for the insane. Worse still, the eastern-controlled assembly had refused the Baltimore and Ohio Company a franchise for a track to extend from Harpers Ferry to the Ohio River by way of the Shenandoah, New, and Kanawha valleys. The question of slavery was not, in itself, an issue between east and west. The middle class white residents of the west tended to abhor abolitionists and, without notable exception deplored John Brown's attempt to incite slaves to revolt against their masters.

Nevertheless, when the Virginia state convention voted (April 17, 1861) to secede from the Union, the westerners, in the First Wheeling Convention (May 13–15), repudiated the action, naming a central committee which proceeded at once to put the northwest in a state of defense. The state authorities in Richmond meanwhile proceeded to make a formal alliance with the Confederate States of America and to prepare for the removal of its capital from Montgomery, Ala., to Richmond, Va.

Under the circumstances, loyal leaders in the northwest abandoned their long-cherished desire for separate statehood and joined President Lincoln in his efforts to preserve the Union. To that end it was considered necessary to reorganize the government of Virginia on a loyal basis. The initial steps were taken in the first session of the Second Wheeling Convention (June 11–25). Acting as a constituent assembly, that body elected Francis H. Pierpont governor of the restored government of Virginia and authorized such changes in the wording of the existing constitution as were considered necessary to permit him and the other state agencies, particularly the General Assembly, to function. The work of reorganization was then completed by the General Assembly, which elected John S. Carlile and Waitman T. Willey to the United States Senate to fill vacancies caused by the withdrawals of R. M. T. Hunter and James M. Mason to cast their lots with the Confederacy. As expected, the new senators were seated, and the reorganized government was accepted as sufficient for any contingency, even the approval of the dismemberment of Virginia and the formation of a new state.

The Confederate defeat at Rich Mountain (July 11, 1861) and Gen. Henry A. Wise's retreat from the Kanawha Valley had meanwhile given impetus to a new state movement. Fortunately for those who wished it, the Second Wheeling Convention had only recessed. For the purpose of dealing with the altered situation it was reconvened on Aug. 6, 1861, and on August 20 it adopted a dismemberment ordinance which provided also for the formation of a new state to be called Kanawha. With only "Black Republicans" and abolitionists voting against the proposed new state, the ordinance authorizing it was approved by the participating voters on October 24. An attempt, directed by Gen. Robert E. Lee, to recover northwestern Virginia for the Confederates having failed meanwhile, the makers resolved to widen the bounds of the proposed new state. In fact, some of them wished to include all western Virginia. As a consequence, a constitutional convention, meeting Nov. 26, 1861, extended the boundary to the south so as to make a "well-rounded-out state" and to the east so as to include all of Virginia traversed by the Baltimore and Ohio Railroad. At the same time, the name was changed from Kanawha to West Virginia.

With the sole provision that the proposed state change its constitution so as to provide for the gradual abolition of Negro slavery, the constitution, ratified April 3, 1862, was accepted by the Congress as drafted. As this was a political matter wholly within the province of the Congress, its legality has never been questioned by the courts. Governor Pierpont having agreed to transfer the capital of the reorganized government from Wheeling to some available point in Virginia, Lincoln approved the separate statehood bill as a war measure and West Virginia was admitted as the 35th state on June 20, 1863.

Since Statehood.—Following the Civil War, West Virginia experienced a reconstruction not unlike that to which the former Confederate states were subjected. In 1872 this was ended in part through a new constitution (ratified August 22) drafted by ex-Confederates and liberal Democrats. Thereafter the best efforts of its leaders were directed largely to solving transportation problems and to developing the state's natural resources. For a time the new state led the entire country in developing a progressive free public school system. Later the leadership became preoccupied with material things, and the state fell behind in educational development on both the lower and the higher levels.

From 1871 to 1897 West Virginia was controlled by the Democratic Party. Of the six Democratic governors, E. Willis Wilson alone was a reform liberal. Throughout this period the state rarely exercised its regulatory powers, and reform was at a standstill. In 1882 certain exemptions from taxation accorded to the railroads and the farmers were nullified by court decision.

The Republicans controlled the state administration from 1897 to 1933, with the exception of the administration of Democrat John J. Cornwell (1917–1921). Like their predecessors, the Republicans were economy-minded, and eager to attract non-resident capital. They were more interested in business promotion than social reform. But the impact of the progressive movement with its demand for better schools, conservation of natural resources, improved highways, public health programs, and fair labor practices did not go

unnoticed. The chief problems of state and local governments were inadequate tax revenues, obsolescent administrative machinery, and strained relations between capital and labor.

From the great railway strike of 1877, which had its inception at Martinsburg, to the enactment of the National Labor Relations Act in 1935, West Virginia was the scene of industrial strife which on occasion erupted into open warfare. On the one hand there were the West Virginia coal operators resisting unionization of their mines; on the other, the United Mine Workers of America (aided and abetted by the operators of Pennsylvania, Ohio, Indiana, and Illinois), asserting their right to bargain collectively. The last citadel of resistance was the southern West Virginia "smokeless" field where the operators were a law unto themselves during the "Golden Twenties." But with the paralysis of the coal industry in the 1930's operators and miners alike welcomed the labor legislation of the New Deal, and unionization was effected by default.

Since statehood, West Virginia has had major disputes with neighboring states as follows: the suit brought by Virginia to recover Berkeley and Jefferson counties, settled in favor of West Virginia (1871); the action growing out of the abduction by Kentucky authorities of West Virginia citizens during the Hatfield-McCoy feud, resolved in favor of Kentucky (1888); the litigation initiated by Maryland for the adjustment of common boundaries, settled in 1910 in favor of West Virginia; the Virginia debt issue, finally settled in favor of Virginia (1911–1919); and the successful effort by Ohio and Pennsylvania in enjoining the state from restricting the exportation of natural gas (1923).

From 1933 to 1957 the political history of the state belonged to the Democrats, whose problems stemmed chiefly from depression, war, transition from war-time to peace-time economy, the coal depression, and the need of constitutional reform. As the Republicans assumed control of the executive branch of the government in 1957, they continued the state's effort to keep abreast of neighboring states in conservation, education, highway improvements, industrial expansion, and the promotion of the tourist trade.

CHARLES H. AMBLER,
Revised by FESTUS P. SUMMERS,
History Department, West Virginia University.

WEST VIRGINIA UNIVERSITY, a coeducational state institution located at Morgantown, 100 miles south of Pittsburgh. The university grounds, with an outlook upon the Monongahela River, have an attractive natural site.

The university originated from the national land grant act of June 2, 1862, and from the subsequent action of the state legislature in accepting and carrying out the provisions of the act. Its location at Morgantown was largely determined by the foundation of an educational institution which had already been laid at Morgantown through an academy first established in 1814 and re-established in 1832. On Jan. 30, 1867, the legislature accepted the property of the old Monogalia Academy and on February 7 passed an act permanently establishing the Agricultural College of West Virginia and authorizing the governor to appoint a board of visitors. A department of military science was organized soon thereafter. By an act of Dec. 4, 1868, the name of the college was changed to West Virginia University.

In addition to the original college (arts and sciences) the university maintains colleges of agriculture, commerce, education, engineering, law, and pharmacy; schools of dentistry, journalism, medicine, mines, music and physical education; divisions of military and air science, and agricultural extension; and agricultural and engineering experiment stations. There is also a graduate school. In 1951 the two-year school of medicine was expanded into a four-year school.

The first notable increase in attendance occurred between 1889 and 1897 when women were admitted as students, after a long struggle against conservative opposition.

In 1909 the financial and business affairs of the university were placed under direction of a state board of control appointed by the governor. In 1919, academic control, hitherto exercised by a bipartisan board of regents, was vested in the state board of education. In 1927 the financial and business affairs of the university were vested in a seven-member board of governors (increased to nine members in 1947).

WEST WARWICK, town, Rhode Island, in Kent County, 11 miles south-southwest of Providence at an altitude of 135 feet, on the Pawtuxet River, two state highways, and the New York, New Haven, and Hartford Railroad. The town is noted for its textile manufactures which include woolen, cotton, rayon, and silk goods, and lace, yarn, and braid. It also manufactures metal products and its agricultural industries include poultry, dairy, and truck farming.

West Warwick was separated from Warwick and incorporated in 1913. It comprises the villages of River Point, its administrative center, Arctic, its railroad station, Crompton, Centreville, Natick, and Phenix. Pop. (1950) 19,096.

WEST YORK, borough, Pennsylvania, just west of the city of York in York County, at an altitude of 370 feet, served by the Pennsylvania and the Western Maryland railroads and state and federal highways. Chiefly an industrial community, West York manufactures machinery, pottery, hosiery, and furniture. The borough was incorporated in 1905 and the government is administered by mayor and council. Pop. (1950) 5,756.

WESTBOROUGH or **WESTBORO,** wĕst'bûr-ô, town, Massachusetts, in Worcester County, nine miles east of Worcester at an altitude of 298 feet, served by the Boston and Albany Railroad. Surrounded by a farming region, yielding apples, peaches, and poultry products, Westborough is chiefly an industrial community. Among its manufactures are abrasives, cotton and woolen articles of clothing, and narrow fabrics. The town also has tanneries and machine shops. Located here are a high school, the Lyman School, which is a state correctional school for boys, and a public library.

Westborough was settled around 1675, and received its first charter in 1717. Its government is administered by a board of selectmen and New England town meeting. Pop. (1950) 7,378.

WESTBROOK, city, Maine, in Cumberland County, six miles east of Portland on the Presumpscot River at an altitude of 85 feet, served by branches of the Boston and Maine Railroad and bus lines connecting it with Portland. The river furnishes considerable water power which is used by the leading industries, the manufacture of textiles and paper. Cotton goods were first manufactured here about 1830 and in 1874 the manufacture of silk was begun. In 1854 Samuel D. Warren purchased a paper factory here and the same concern had a daily output of over 400 tons in 1951. The city also has flour mills and machine shops, and its chief cotton and silk products are dress goods, cotton warp, and seamless bags. The Walker Memorial Library was erected here in 1894.

In 1814 sections of this region called Ammoncongin and Saccarappa were incorporated into the town of Westbrook, in honor of Col. Thomas Westbrook. It was chartered as a city in 1891. The principal sections of the city are West End, East End or Cumberland Mills, Pride's Corner, and Highland Lake. The government is administered by mayor and council. Pop. (1950 12,284.

WESTCHESTER, village, Illinois, in Cook County, 14 miles west of Chicago, of which it is a suburb. It is served by the Illinois Central and the Indiana Harbor Belt railroads and two federal highways. Westchester was incorporated in 1925 and is chiefly a residential community. Pop. (1950) 4,308.

WESTCOTT, wĕs(t)'kŭt, **Brooke Foss,** English bishop and theologian. b. Birmingham, Jan. 12, 1825; d. Bishop Auckland, Durham, July 27, 1901. He was graduated from Trinity College, Cambridge, in 1848, was elected a Fellow of his college in 1849 and in 1851 was ordained in the English Church. He was assistant master at Harrow 1852–1869, and here he remained till 1869, when he became a residentiary canon of Peterborough. He became canon of Westminster in 1883 and on the death of his friend, Lightfoot, bishop of Durham, was appointed his successor in 1890, and in this see he remained until his death.

Westcott showed a deep interest in the lot of the miners in his diocese, which won him their genuine esteem, and he was very successful in preventing and settling industrial disputes. From 1870 to 1890 he was regius professor of divinity at Cambridge and during his tenure of the office exercised a powerful and abiding influence on undergraduates and scholars.

As a scholar and theologian Westcott's position was a very high one. As a textual critic he is best known for his share in the revision of the Greek text of the New Testament, which occupied him and J. F. A. Hort for 28 years, and resulted in the publication of their important work, *The New Testament in the Original Greek,* in 1881. The text formed the basis of the Revised Version of the New Testament. His other published works include *General Survey of the History of the Canon of the New Testament During the First Four Centuries* (1855), which has gone through many editions; *Introduction to the Study of the Gospels* (1860); *A General View of the History of the English Bible* (1868); *The Paragraph Psalter* (1879); *The Revelation of the Risen Lord* (1882); *Social Aspects of Christianity* (1887); *Essays in the History of Religious Thought in the West* (1891); *The Gospel of Life* (1892); *The Incarnation and Common Life* (1893); *Lessons of the Revised Version of the New Testament* (1894); *Christian Aspects of Life* (1895); *Lessons from Work* (1901), and *Words of Faith and Hope* (1902).

WESTCOTT, Edward Noyes, American writer and banker: b. Syracuse, N. Y., Sept. 26, 1846; d. there, March 31, 1898. He was educated in the schools of Syracuse and at 16 became a bank clerk. From 1866 to 1868 he lived in New York City but returned to his native place where he worked for various banks.

In June 1895 tuberculosis forced his retirement, and during the summer at Lake Meacham in the Adirondacks and the following winter in Italy, he wrote his well-known novel, *David Harum* (q.v.). His manuscript was refused by several publishers. It was only accepted in January 1898, two months before his death, and Wescott did not live to see his book printed in September of that year. Its subsequent success was manifested in the sale of over a million copies.

WESTERLY, town, Rhode Island, in Washington County, 69 miles east of New Haven on the Pawcatuck River and the Connecticut boundary, and served by the New York, New Haven, and Hartford Railroad. It is at an altitude of 15

feet and comprises several villages. In environment and character it combines rural, seaside, and industrial elements. Summer resorts and Long Island Sound beaches are nearby. Granite is quarried in the county and the town manufactures textiles and metal products and has a food canning industry.

In the late 17th and the 18th centuries, shipbuilding was an important industry. The first permanent settlers in the area were John and Mary Babcock, in 1648. Westerly's charter dates from 1669. Pop. (1950) 12,380.

WESTERMANN, wĕs'tĕr-măn, **William Linn,** American historian: b. Belleville, Ill., Sept. 15, 1873. With degrees from the University of Nebraska and the University of Berlin, he taught Latin, Greek and history in several American schools and universities and was professor of history at Columbia University from 1923 to 1948. He was the author of *Story of the Ancient Nations* (1912), the editor of *Westermann's Classical and Historical Map Series* (1918), and a collaborator in the publishing of three series of *Greek Papyri* (1926, 1931, 1933).

WESTERMARCK, Edward Alexander, Finnish philosopher and anthropologist: b. Helsingfors, Nov. 20, 1862; d. Lapinlahti, Finland, Sept. 3, 1939. He was educated at the University of Finland, and he became professor of moral philosophy there in 1894. From 1907 to 1930 he occupied the Martin White professorship of sociology at the University of London; and thereafter he was professor of philosophy at Turku University until his retirement in 1935. He was an authority on the history of marriage, morals, and the social customs of mankind. His works included: *The History of Human Marriage* (1891; 5th ed. 3 vols. 1921); *The Origin and Development of the Moral Ideas* 2 vols. (1906–08); *Marriage Ceremonies in Morocco* (1914); *A Short History of Marriage* (1926); *Ritual and Belief in Morocco* (1926); *Wit and Wisdom in Morocco* (1930); *Ethical Relativity* (1932); *Early Beliefs and Their Social Influence* (1933); *The Future of Marriage in Western Civilization* (1936); *Christianity and Morals* (1939).

WESTERN AUSTRALIA, largest of the states of the Commonwealth of Australia. On the north, west, and south it is bounded by the Indian Ocean, and on the east by the Northern Territory and South Australia. The greatest length is 1,480 miles, north to south; and the greatest breadth is almost 1,000 miles. The area is 975,920 square miles, and the population in June 1944 numbered 485,407 (252,508 males and 232,899 females). The capital is Perth (pop. 1941, 230,000), and Fremantle (28,169) is the principal port; other cities are Kalgoorlie (10,500) and Bunbury (5,700).

The coastline measures about 3,000 miles, and except on the south is indented by numerous bays, creeks, and estuaries. The chief rivers are the Ord and Fitzroy, on the north; and De Grey, Fortescue, Ashburton, Gascoyne, Murchison and Swan, on the west. Perth is situated on the banks of the Swan River. Few of the rivers are large and navigable. The greater part of the seaboard is separated from the interior by a low range of hills running parallel to it, and covered with forests. To a large extent, the country is an alternation of ridges and hollows, sandy, without grass, and clothed with bushes and scrubby timber. The fertile land exists in patches, and some of it is of a very rich character. Large forest areas are covered with jarrah, a species of eucalyptus in great request for building purposes. Another eucalyptus is the karri, found principally in the southwest, where, also, are numerous forests of sandalwood trees. Pearl oysters, bêche-de-mer, and tortoise shell are obtained off the northwest coast. Western Australia is the principal gold-producing state in the Commonwealth; 45,588,000 fine ounces of gold were mined there down to 1939. Coal is also produced in considerable quantity, and other minerals of commercial importance comprise silver, lead, copper, tin, iron, zinc, and wolfram.

The pastoral and agricultural industries are of great importance. Sheep are raised in considerable numbers in the southeast and center of the state, and cattle in the north, where the rainfall is heavier. Horses and hogs are relatively fewer than in other parts of the Commonwealth. Wheat is by far the largest cereal crop, and oats rank second in importance. Other crops include barley, hay and green forage; vines and orchard fruits do well.

Although the first settlement was made in 1826, Western Australia was not constituted a colony until June 1829. From 1850 to 1868 it was a place for the transportation of convicts. The colony obtained responsible government in 1890; and on Jan 1, 1901, it became an origin-constituent state of the Commonwealth of Australia (q.v.)

WESTERN EMPIRE, The, the western portion of the Roman empire, consisting of Italy, Illylricum, Spain, Gaul, Britain and Africa, as distinguished from the Eastern or Byzantine empire, comprising the eastern half of the Balkan Peninsula, Greece, Egypt, Syria and Asia Minor, so far as Persia. This partition of the Roman empire occurred in 364 when Valentinian I shared the imperial authority with his brother Valens, who ruled in Constantinople as emperor of the East, while Valentinian ruled in Rome as emperor of the West. The partition became final in 395 when Theodosius the Great divided the Roman world between his two sons Honorius, who became emperor of Rome and the West, and Arcadius, who became emperor of Constantinople and the East. The Western empire terminated in 476. See Byzantine Empire; Rome.

WESTERN INDIA STATES AGENCY, a grouping of 16 Indian States, west of Bombay Province, in direct political relations with a British Resident whose headquarters are at Rajkot. The States, which have internal autonomy, comprise Bhavnagar, Cutch, Dhrangadhra, Dhrol, Gondal, Jafrabad, Junagadh, Limbdi, Morvi, Nawanagar, Palitana, Porbandar, Radhanpur, Rajkot, Wadhwan, and Wankaner. The area of the Agency is 37,894 square miles; at the census of 1941 the population totaled 4,904,156.

WESTERN ISLANDS. See Azores; Hebrides.

WESTERN MARYLAND COLLEGE, located at Westminster, Md. It was founded under the auspices of the Methodist Protestant Church, and was first opened to students in 1867.

It was the first college in the South to offer equal educational privileges to both sexes. The preparatory school, established in 1899, has been discontinued, and its quarters, Levine Hall, converted into a men's dormitory. The campus is situated on elevated ground in the western part of the city. The degree of A.B. is conferred for the completion of a four years' course in the classical, scientific or historical field. Courses are also given in music, art and elocution. The enrollment for the year 1949–1950 was 825 and the faculty numbered 55.

WESTERN ONTARIO, University of, Canadian university, situated at London, Ontario. It was founded in 1878 as a college in connection with the Church of England. In 1949–1950 there were 3,323 students and 230 teachers. In the same year the library had 187,000 volumes. Degrees and diplomas up to, and including, Ph.D. are given.

WESTERN RESERVE, or CONNECTICUT RESERVE, that portion of the Northwest Territory (q.v.) reserved by Connecticut when, in 1786, that state ceded to the United States other parts of the territory claimed under the charter of 1662, which granted to Connecticut lands limited east and west by the sea. This section of land is what is now included in the northeastern part of Ohio; it was all the territory between lat. 41° and 42° 2′ N., and extending 120 miles from the western boundary of Pennsylvania. In 1795–1796 Connecticut sold this land, except 500,000 acres, to a number of men who established what was known as the Connecticut Land Company. At first settlers hesitated about purchasing any of the land on the "Reserve," fearing the validity of the title, but when the State of Connecticut yielded all claim to the government, there was no longer any doubt about the titles. There were a large number of colonists from Connecticut who settled on this "Reserve"; counties were organized, 13 in all, which were in whole or in part from lands of the "Reserve." (See NORWALK, OHIO.) The people were characterized by their thrift, industry and the manner in which they established schools. A large part of the money received by Connecticut for the sale of the lands was set aside "as a perpetual fund, the interest of which should be appropriated to the support of schools." This school fund was the means of influencing in Ohio a unique system of education, in some respects different from that of any other state.

WESTERN RESERVE UNIVERSITY, an endowed, independently controlled university, located in Cleveland, Ohio, was the first institution offering higher education in Connecticut's Western Reserve, having been chartered in 1826 as Western Reserve College, and located at Hudson, Ohio, twenty miles southeast of Cleveland. The Cleveland Medical College was organized in 1843 and became the medical department of Western Reserve College in 1844.

The institution was moved to Cleveland in 1882, and the name was changed to Western Reserve University. The undergraduate college for men took the name of Adelbert in recognition of a substantial gift from Amasa Stone whose son, Adelbert, died while a student at Yale University.

In 1888 undergraduate instruction in arts and sciences was made available to young women by the organization of a coordinate college for women which is now known as Flora Stone Mather College.

The university now consists of eleven schools and colleges, three offering degrees in arts and sciences and business, and eight offering graduate or professional degrees as follows: Adelbert College and Flora Stone Mather College, for men and women, respectively; Cleveland College, located on the Public Square, and enrolling both full-time and part-time students, the majority of whom are adults; Graduate School; the School of Medicine; the School of Dentistry; the School of Library Science; the School of Applied Social Sciences; the Frances Payne Bolton School of Nursing; the School of Architecture; and the Franklin Thomas Backus School of Law.

From its founding in 1826, the college, and then the university, adopted and maintained high standards of scholarship with the result that by 1840 its faculty was recognized as being superior to any in the Middle West, and equal to that of many of the older institutions in the East. Western Reserve College was the pattern to be followed in the founding of many other colleges in Ohio and in other parts of the Middle West. Frequently it was referred to as the "New England college of the West" and also as the "Yale of the West." In its early days the institution played a leading part in the cultural, educational, and religious development of Connecticut's Western Reserve. In later years, its graduates occupied positions of great influence and leadership in the industrial development of northeastern Ohio.

During the 20th century Western Reserve University has developed as an urban university, placing more and more emphasis on serving the educational and cultural needs of an urban community based on an industrial economy. The development of Cleveland College, located in the heart of the city, has made available a great variety of educational opportunities to citizens of all ages. At the same time the university has continued its tradition of small undergraduate colleges, thus making available to its students the opportunities both of the small college and of the large university.

The university has grown more rapidly than the community which it serves and by which it has been supported. The population of Cleveland has increased from 381,768 in 1900 to 914,808 in 1950, an increase of 139 per cent. In the same period the number of students has grown from 717 to 17,980, an increase of 240.7 per cent. The university's assets have increased from $2,634,427 in 1902 to a total of $35,175,174.94 in 1950.

The university works in close cooperation with the other educational institutions of the community. The Cleveland Museum of Art, the Cleveland Symphony Orchestra, the Cleveland Institute of Art, Case Institute of Technology, the University Hospitals are all located in the University Circle area and have arrangements for the interchange of personnel and facilities with the university.

JOHN SCHOFF MILLIS,
President, Western Reserve University.

WESTERN SPRINGS, village, Illinois, in Lyons Township, Cook County, is a residential community (altitude, 670 feet), situated 17 miles southwest of Chicago on the Chicago, Burlington & Quincy Railroad, and on federal and state highways. Its name derives from mineral springs which once abounded in the vicinity and were

notable in that, during dry weather, they raised mounds of earth from which the water jetted forth. On the grounds of the Western Springs Country Club there was located in 1843 one of the stations of the Underground Railroad where slaves were sheltered on their flight to Canada.

The village was settled by Quakers (about 60 families), and was incorporated in 1886. It is governed by an elected president and six trustees. It has a public library; private, parochial (Lutheran), and public schools; five Protestant churches, a newspaper, a Little Theater group, symphony orchestra, and a number of clubs including branches of the American Association of University Women and the League of Women Voters. Pop. (1950) 6,120.

WESTERNPORT, town, Maryland, in Allegany County; altitude 922 feet; on the north branch of the Potomac River; at the head of navigation; 27 miles southwest of Cumberland; on the Western Maryland Railroad. It was once a prosperous coal-mining town. Pop. (1950) 5,439.

WESTFIELD, city, Massachusetts, in Hampden County, altitude 154 feet, on the Westfield River, the Boston and Albany, and New York, New Haven and Hartford railroads; and one state and two federal highways, 9 miles west of Springfield. There is a city airport. Westfield was famous for its whips in the 19th century; at one time 40 establishments here made whips. Finally this became a premium and carnival trade only. Now the main manufactures are bicycles, boilers and radiators, textile machinery, envelopes and other paper products, brushes and mops, thread, bricks, wood and paper boxes. Here are Massachusetts State Normal School (1844); a state sanatorium for tuberculosis and cancer; the Atheneum (1864) which houses a good library; the Edwin Smith Historical Museum; and the Jasper Rand Art Museum. Fowler Tavern was frequented by George Washington; its front door is now in the American Wing of The Metropolitan Museum in New York. An Indian trading post here in 1640 was called Woronoco (now the name of the city park). In 1669 Westfield separated from Springfield, and remained a town till 1921, when it was chartered as a city. It has a mayor and council. Pop. (1940) 18,793; (1950) 20,961.

WESTFIELD, residential town, New Jersey, in Union County; altitude 130 feet; 18 miles southwest of Jersey City; on the Central of New Jersey Railroad; skirted by State Highway 29. Many residents commute to business in New York and other nearby cities. Places of interest include Mindowaskin Park, and Scudder House, headquarters of Gen. William Alexander during the Revolutionary War. It has excellent public and parochial schools; mayor and council government. Pop. (1940) 18,458; (1950) 21,335.

WESTFIELD, village, New York, in Chautauqua County; altitude 748 feet; two miles from Lake Erie, and six miles from Lake Chautauqua; on the New York Central, and New York, Chicago and St. Louis railroads. It is in the Chautauqua grape belt, and the manufacture of unfermented grape juice is the leading industry. It is known as the grape juice capital of the world. Other products include tomato juice and canned fruits. Fisheries are important. Pop. (1940) 3,434; (1950) 3,649.

WESTFORD, town, Massachusetts, in Middlesex County; altitude 160 feet; 25 miles northwest of Boston; on the Boston and Maine Railroad. First settled in 1653, it was incorporated as a town in 1729. It is in an agricultural and fruit-growing section. Industries include the manufacture of worsteds, machinery, and foundry products. Old Fletcher Tavern, dating from 1713, is interesting. Pop. (1940) 3,830; (1950) 4,240.

WESTINGHOUSE, George, American inventor: b. Central Bridge, N. Y., Oct. 6, 1846; d. New York, March 12, 1914. He entered the machine shop of his father, a manufacturer of agricultural implements, when very young and early evinced an inventive genius, designing at 15 a rotary engine. He served in the Union Army in 1863–1864, and in 1864–1865 was assistant engineer in the United States Navy, after which he studied at Union College for two years. He continued his interest in mechanics, his first invention of importance being a railway frog. In 1868 he introduced the famous Westinghouse brake (see AIR-BRAKE), which has since been developed to a remarkable degree of efficiency, and has come into international use. At first his invention was scouted as impracticable. The story is told that he interviewed Commodore Vanderbilt, and explained his designs. The Commodore is said to have replied, "If I understand you, young man, you propose to stop a railroad train with wind; I have no time to listen to such nonsense." A few years later the "impossible" device was operating on all the Commodore's lines. Mr. Westinghouse was one of the pioneers in introducing alternating-current machinery, and he succeeded in securing the use of this method at the Chicago Exposition in 1893. He had also made numerous improvements in railroad signaling, and through his devices the safety of high-speed railway traveling has been greatly increased. He erected extensive works in this country and abroad for the manufacture of his various inventions, was president of over 30 corporations, and proved to be as good a businessman as he was a skilled mechanician. He received the Order of Leopold from the Belgian king in 1884, and in 1889 the Royal Order of the Crown from the king of Italy. He was also decorated with the French Legion of Honor.

WESTLAKE, Nathaniel Hubert John, British painter, designer and writer in art: b. Romsey, 1833; d. London, May 9, 1921. He studied painting and design under the British artists, William Dyce and J. R. Herbert, also at Antwerp and Paris. At a friend's suggestion he became associated with a firm of glass painters as designer, and about 1880 became art manager and partner of the firm. He was a frequent exhibitor at the Royal Academy, Arts and Crafts, and other art centers. Examples of his paintings are in St. John's Church, Richmond; Portsmouth Cathedral; St. Augustine's Church, Tunbridge Wells; Bute Memorial Chapel, Cardiff Castle, Wales; and the chapel of Maynooth College, Ireland. Notable examples of his glass work in England and the United States are in St. Paul's Cathedral, London, the cathedrals of Peterborough and Wor-

cester, the Gate of Heaven Church, South Boston, Mass., the Via Crucis of Saint Francis's, Notting Hill, London. He designed Salviati's mosaic of Blessed James of Ulm at the South Kensington Museum, London, the apse mosaic in the Newman Memorial Church, Birmingham, and collaborated with many famous architects. His publications include 'Outlines of the History of Design in Mural Painting' (3 vols.); 'History of Painted Glass' (4 vols); 'True Portraiture of St. Francis'; 'Sketches at Malines Exhibition.' He edited 'Reproduction of Royal Manuscripts, 2 B VII, British Museum'; 'Queen Mary's Psalter,' etc.

WESTLAKE, William, American inventor: b. Cornwall, England, 23 July 1831; d. Brooklyn, N. Y., 28 Dec. 1900. He came to the United States in 1847, settled in Milwaukee, Wis., and there was employed in a printing office. He was subsequently an apprentice to a tinsmith, and in 1853 made for Captain John Ericsson the models for his first hot-air engine. He entered the employ of the La Crosse and Milwaukee Railroad Company in 1857, and soon after began the series of inventions which made him famous. Among them are the Westlake car heater, the globe lantern, the first practical car lamp, the oil cook stove, the stoveboard, etc.

WESTLAND, New Zealand, a provincial district in South Island, bounded north by Nelson district, south by Otago, west by the ocean and east by Canterbury, from which it is separated by the chain of the Southern Alps. It is about 200 miles long and about 25 miles in average breadth, its area being about 4,881 square miles. It consists principally of hills branching off from the great alpine system, intersected by narrow bush-clad valleys, and merging coastward into undulating plateaus, river valleys and shelving coasts. The streams are numerous but short. Practically the whole of the district is covered with forest. Large tracts can be prepared easily for pastoral purposes, but there is little ground suitable for agriculture. Gold is found in the valleys of the rivers, especially in those of the Arahura and Waiho, and gold-bearing quartz is also worked in some places. Silver, copper, iron and tin are among the other metallic treasures of the district, which has also yielded much coal, especially from the valley of the Grey. The climate is equable and temperate. The rainfall is heavy, and snow lies on the high mountains during much of the year. The capital is Hokitika, the other chief towns being Greymouth, Brunnerton, Kumara and Ross. Railways connect Greymouth with Hokitika, Jackson and Reefton (in Nelson district). Westland was formerly part of Canterbury district. Pop. about 15,025.

WESTMACOTT, wĕst'mą-kŏt, **Richard,** English sculptor, son of Sir Richard Westmacott (q.v.): b. London, 1799; d. there, 19 April 1872. He studied under his father and also in Italy 1820–26, and after returning to England rose to prominence in his art. In 1857 he succeeded his father as professor of sculpture at the Royal Academy, having become associate member of the academy in 1838 and a full member in 1849. His style resembled that of his father in many respects He published a 'Handbook of Sculpture' (1864) and a pamphlet 'On Coloring Statues.'

WESTMACOTT, Sir **Richard,** English sculptor: b. London, 1775; d. there, 1 Sept. 1856. He was the son of Richard Westmacott, also a sculptor, and was early trained to a knowledge of art by his father. In 1793 he was sent to Rome to study his profession under Canova, and there gained the annual gold medal for sculpture given by the Pope at the Academy Saint Luke. He also obtained a first prize for sculpture at Florence, and was elected a member of the Academy there. In 1798 he returned to England and rose rapidly in estimation as an artist. Many of the monuments in Saint Paul's Cathedral are by him, and that building forms, in some respects, a gallery of his works. The figure of a Welsh girl in a monument to the memory of Lord Penrhyn, at Penrhyn, in North Wales, is considered by many as his best creation. He designed also the statue of Nelson in Birmingham, besides figures of Addison, Pitt and many others. He became an associate of the Royal Academy in 1805, a full member in 1811 and in 1827 succeeded Flaxman as lecturer to the academy on sculpture. He was knighted in 1837.

WESTMEATH, Irish Free State, county of the province of Leinster, having Meath on the east, Roscommon on the west, Cavan on the north and King's County on the south; greatest length, east to west, about 40 miles; greatest breadth, north to south, about 35 miles; its area is 708 square miles, or 453,468 acres, of which 111,752 are under tillage. The surface is generally level, the land is chiefly in pasture. Mullingar is the chief town, but Athlone is the great manufacturing centre. Pop. 56,796.

WESTMINSTER, London, England, a metropolitan and Parliamentary borough, formerly the ancient city and Liberty of Westminster, which still retains its civic title and certain privileges. Area, 2,502 acres. It is bounded on the south and east by the river Thames; east by the city of London, from which it was separated by the former Temple Bar; north by Holborn, Marylebone and Paddington, and west by Kensington and Chelsea. It is connected with Lambeth by Vauxhall, Lambeth, Westminster and Waterloo bridges. It has the highest valuation of any of the London boroughs (£10,728,957 in 1936) not excepting the City of London. The city contains some of the finest and most imposing buildings in London and teems with historical and literary associations. All the metropolitan royal palaces are within its limits and also Westminster Abbey, the Houses of Parliament, a fine modern Roman Catholic cathedral, the principal government buildings, the headquarters of the metropolitan police force, the National Gallery and the Tate Gallery, Burlington House, Somerset House and the principal theatres and opera-houses. It is divided into three Parliamentary constituencies, each returning one member, Saint George's, Hanover Square, the Abbey and Strand.

The History of Westminster goes back to a very early period. It became a city when, in 1540, Henry VIII made it the see of a bishop, and even though the see was suppressed 10 years later it retained the right to the style of city. The only (Anglican) bishop of Westmin-

ster was Thomas Thirlby. Since 1831 a branch of the Grosvenor family has borne the title of marquis, and since 1874 of duke of Wesminster. Pop. (1951) 98,895. See also LONDON.

WESTMINSTER, city, Maryland, Carroll County seat, altitude 744 feet, on the Western Maryland Railway and a federal highway, 28 miles northwest of Baltimore, on Parr's Ridge. The city is in an agricultural section and holds weekly auction markets of livestock, eggs, and poultry. Vegetables and fruits from the surrounding country are canned here, and canning and poultry equipment are manufactured. Clothing, shoes, flour, fertilizer, upholstery, meat packing, floor covering are other factory products. The county courthouse and County Historical Society are housed in colonial buildings.

In the western part of the city, on College Hill, are the Western Maryland College (Methodist Protestant, coeducational, 1866) and the Westminster Theological Seminary, of the same denomination, which also has a home for the aged here. The government is vested in a mayor and five councilmen, elected annually on a nonpartisan basis. Westminster was settled in 1764 and became a center for the nonepiscopalian Methodist organization that grew up in Maryland about 1830. Pop. (1940) 4,692; (1950) 6,140.

WESTMINSTER ABBEY. See LONDON —*Ecclesiastical London.*

WESTMINSTER ASSEMBLY OF DIVINES, a celebrated assembly held in the middle of the 17th century for the settlement of a general creed and form of worship throughout Great Britain, at a time when Presbyterianism had gained a strong position in England as well as in Scotland. On the 23d of Nov. 1641 the House of Commons (Long Parliament) addressed to the king a remonstrance desiring a synod of the most learned and pious men throughout the island for the settling of the government of the church; but it was not until 1643, after the civil war had begun, that an ordinance was passed (on June 12) convoking the long-proposed assembly of divines. By this act 121 clergymen, with 10 lords and 20 commoners as lay assessors, were nominated as constituents of the assembly. The assembly began its sittings on July 1, 1643 in Henry VII's Chapel, at Westminster Abbey, but in the meantime a proclamation forbidding the assembly to meet had been issued by the king on June 2, which had the effect of inducing the greater part of the Episcopal members to absent themselves, and Episcopacy was thus almost entirely unrepresented. The majority of those who remained were Presbyterians, but there was a powerful and energetic minority of Independents. A deputation was now sent along with commissioners from the English Parliament to the general assembly of the Scottish Church and the Scottish Convention of Estates, soliciting their cooperation in the proceedings of the Westminster Assembly, and accordingly on September 15, four Scottish clergymen, Alexander Henderson, George Gillespie, Samuel Rutherford and Robert Baillie, with two laymen, Lord Maitland and Sir Archibald Johnston of Warriston, were admitted to seats and votes by an act of the English legislature. The assembly continued to hold its sittings until Feb. 22, 1649. Among the results of its deliberations were the *Directory of Public Worship,* which was presented to Parliament on April 20 and ratified on Oct. 2, 1644; the *Confession of Faith* presented to Parliament in October and November 1646 and ratified with a few verbal alterations in March 1648; the *Shorter Catechism,* presented to the House of Commons on Nov. 5, 1647 and the *Longer Catechism* on Sept. 15, 1648. In the latter period of the sittings of the assembly the growing power of the Independent party in Parliament presented a serious obstacle to the carrying into effect of its recommendations, though in 1648 an order of Parliament was pronounced declaring "all parishes and places whatsoever," with the exception of chapels for the king and peers, to be under the Presbyterian form of church government. The accession of Cromwell to power destroyed the hopes of the Presbyterians, and on the Restoration the whole proceedings of the Westminster Assembly, with the ratification of Parliament, were annulled as invalid.

While this celebrated convocation was thus allowed, as regards England, to remain almost inoperative, its deliberations have left on Scotland and on Presbyterianism, as established in the United States, an impress which will never be effaced. The present standards of the Presbyterian churches are made up of the various formularies above enumerated. They were ratified by the Scottish General Assembly as follows: The *Directory of Public Worship* in February 1645; the *Confession of Faith* in August 1647, and the *Longer and Shorter Catechism* in July 1648. See also PRESBYTERIANISM.

WESTMINSTER COLLEGE, located at Fulton, Missouri. It was founded in 1853 by the Missouri Synod of the Presbyterian Church. Though badly crippled during the Civil War by reduction in numbers and loss of endowment, the college continued its work throughout the war. In 1901 an amendment of the charter placed the college under the joint control of the southern and the northern synods of Missouri. The college formerly conferred the three degrees of A.B., B.L. and B.S. for the completion of the classical, literary and scientific courses respectively; but recently arranged its course in three groups corresponding to the former three courses, and confers the single degree of A.B. Each group includes required and elective studies. Bible study is required and Hebrew is among the electives. There is also an academy offering a classical and a literary and scientific course and commercial courses. The campus comprises over 40 acres of ground on a wooded slope bordering on Stinson Creek. More than one-third of the students regularly work all or part of their way through college. Enrollment annually is about 400 men.

WESTMINSTER COLLEGE, located at New Wilmington, Pennsylvania. It was chartered in 1852, as Westminster Collegiate Institute under the auspices of the United Presbyterian Church. The board of trustees now consists of 40 members, the majority of whom are elected by two synods of that church. The name was changed to Westminster College in 1892. The college offers two four-year courses, leading to degrees, the classical and the scientific, and confers the degrees of A.B. and B.S. The work of the scientific course is mostly required; that of the classical course largely elective in the junior and senior years. Greek is required for

the A.B. degree. There are also a three years' preparatory course, a department of music and an art department. The college has a pleasant situation on elevated ground, some parts of the campus commanding a fine view. The buildings are the main building, scientific hall, the ladies' hall and the gymnasium. The average annual enrollment is about 900.

WESTMINSTER CONFESSION OF FAITH. See CONFESSION OF FAITH, WESTMINSTER.

WESTMINSTER PALACE, London, England, an alternative name for the Houses of Parliament, perpetuated from the ancient palace built by Edward the Confessor as a royal residence and which contained the various national administrative and judicial offices. With the exception of the great hall, the building was destroyed by fire in 1834. The site is occupied by the new palace of Westminster or Houses of Parliament. See LONDON—*Historic Buildings and Other Points of Interest.*

WESTMINSTER SCHOOL, an ancient English public school established in Westminster Abbey by Henry VIII, and refounded in 1560 as St. Peter's College by Queen Elizabeth. The school buildings closely adjoin the abbey, several of them having once been a part of the domestic buildings of the abbey, the great schoolroom being originally the monks' dormitory; others, such as Ashburnham House, belonging to the Post Reformation period. The institution was reorganized in 1868 as one of the seven principal public schools of England. The Westminster play, for which this school is noted, is a yearly performance by the pupils of some Latin comedy. Many eminent Englishmen have been educated at this school.

WESTMINSTER STANDARDS. See PRESBYTERIANISM.

WESTMOUNT, wĕst'mount, Quebec, Canada, on Montreal Island, a residential section of Greater Montreal. It is situated immediately to the west of the city proper on the southwestern slope of Mount Royal commanding extensive views. Incorporated as a town in 1873 and as a city in 1908, it has a public library, the Herbert Reddy Memorial Hospital, seven banks, a weekly newspaper, and a "business association." The lower level of the city is traversed by the Canadian Pacific and Canadian National railways, and there are 15 industries the largest of which is a manufactory of medical and pharmaceutical preparations. The city is administered by a mayor and five aldermen elected for a two-year term. Pop. (1941) 26,047; (1951) 24,388, about 74 per cent of English-speaking origin.

WESTON, Edward, American electrician: b. London, England, May 9, 1850; d. Montclair, N. J., Aug. 20, 1936. He came to the United States in 1870 and engaged as chemist to a nickel-plating company. He devised various improvements in the process of nickel-plating and invented several dynamo-electric machines, establishing at Newark, N. J., in 1875, the first factory in America devoted exclusively to the manufacture of the latter class of machines. After the consolidation of his plant with another company in 1881 he continued as its electrician until 1888 when he formed the Weston Electric Instrument Co., Waverly, N. J., becoming president. He improved appliances for lighting by electricity. He was one of the founders of the American Institute of Electrical Engineers and president in 1888.

WESTON, Edward Payson, American pedestrian: b. Providence, R. I., March 15, 1839; d. Brooklyn, N. Y., May 13, 1929. In his youth he was a reporter on the New York *Herald* and was valued because of his ability to bring his night copy back to the office on foot quicker than could others traveling on the horse-cars of the period. He attracted attention in 1861 by walking 443 miles in 208 hours to attend the inauguration of Abraham Lincoln. His professional career began in 1867, when he walked 1,326 miles from Portland, Me., to Chicago, in 26 days. Later he engaged in six-day races, first in the effort to make 500 miles in a week, and when that record was passed he learned to run and created higher records. Some years later he again took to long walks on the highway, and in 1907 repeated his trip from Portland, Me., to Chicago, bettering the time 29 hours. Next he walked from New York to San Francisco, 3,895 miles (1909), in 104 days, 7 hours. The following year he walked back to New York, 3,500 miles, in less than 77 days. He lectured on pedestrianism and temperance in cities of the United States and England.

WESTON, wĕs'tŭn, town, Ontario, in York County, immediately northwest of Toronto on the Canadian National and Canadian Pacific railways. Electric railway communication with Toronto is supplied by the Toronto Transportation Commission. Though largely a residential suburb of Toronto, amid pleasant surrounding country, it has 45 industrial establishments of a diversified character which employ 2,438 persons and produce to the value of $20,012,274 (1949). Heating and cooking apparatus, bicycles, automobile supplies and stone products are the principal manufactures. There are seven churches, six primary schools, high and vocational schools, a public library of 10,937 volumes, a weekly newspaper and a board of trade. The immediate neighborhood was settled early, but the municipality was not incorporated until 1881. Pop. (1941) 5,740; (1951) 8,646.

WESTON, town, West Virginia, and Lewis County seat; altitude 1,100 feet; on the Monongahela River, here not navigable; 25 miles southwest of Clarksburg; on the Baltimore and Ohio Railroad. It is in a hilly region, where sheep and cattle are raised. The county has coal, oil, and gas; great quantities of the gas are piped to large cities. The manufacture of glass tableware is the principal industry. There is a public library and the high school library is also well equipped. The city is governed by a council, composed of a mayor and four councilmen elected by the people. Weston was incorporated in 1818 and received its charter in 1847. Pop. (1950) 8,945.

WESTPHALIA, wĕst-fāl'yà; -fā'lĭ-à, Germany, a name originally given (1) to a large region of Germany; (2) to a duchy; (3) to an ancient imperial circle; (4) to a kingdom; (5) to a province of Prussia. These various divisions will be described in the above order.

1. The name of Westphalia was given from the second half of the 8th century to the west-

ern part of the ancient Duchy of Saxony incorporated by Charlemagne in the kingdom of the Franks, that is, to all the country between the Weser and Rhine while the territory between the Elbe and Weser was called Eastphalia (Ostfalen). The latter name was lost after the dissolution of the Duchy of Saxony in 1180; the former was retained and was applied in the first place to a newly-erected duchy.

2. **Duchy of Westphalia.**—This was formed out of the part of the old Duchy of Saxony, then called Süderland or Sauerland, on the Upper Ruhr and Lenne. When Henry the Lion, the last of the old dukes of Saxony, was put under the ban of the empire, this territory was taken possession of by Philip of Heinsberg, archbishop of Cologne, who obtained the title of duke from Frederick Barbarossa. Cologne remained in possession of it until the dissolution of the archbishopric in 1801, upon which it was given, by way of indemnity, to Hesse-Darmstadt. In 1815 it was ceded by this power to Prussia and was united with the Prussian province of Westphalia.

3. **Circle of Westphalia,** one of the 10 circles into which the empire of Germany was divided by Maximilian I in 1512. It comprised the region between Lower Saxony, the Netherlands, Thuringia and Hesse, as well as considerable tracts on the left bank of the Rhine; but the proper Duchy of Westphalia, as an appendage of Cologne, was considered as belonging to the electoral circle of the Rhine. Its total area was 22,175 square miles.

4. **Kingdom of Westphalia.**—The Peace of Tilsit, now Sovetsk (July 1807), had made Napoleon master of all the Prussian territory west of the Elbe and he also kept possession of the territories of the electors of Hesse and Hanover and the Duke of Brunswick. Out of the countries just mentioned he created by decree of Aug. 18, 1807 a kingdom of Westphalia, with an area of 14,712 square miles and a population of nearly 2,000,000. Napoleon gave the kingdom to his youngest brother, Jerome, and on Nov. 15, 1807 a constitution similar to the French was granted to it. The insurrections that broke out in several parts in 1809 occasioned the adoption of various severe measures, and the introduction of an oppressive system of police. At the same time the king was required to bring his army up to a strength of 30,000 men, which produced great disorder in the finances. In 1810 a part of Hanover was added to the kingdom, the whole area of which was now 17,540 square miles. After the Battle of Leipzig (1813) the kingdom was dissolved. On October 26, Jerome was obliged to quit his capital (Cassel) and make his escape from the kingdom, whereupon the territories of which it was composed returned to their former possessors.

5. **The Prussian Province of Westphalia** was formed in 1815 out of some of the provinces which Prussia formerly possessed in the circle of Westphalia. It is bounded on the north by the province of Hanover; on the east by Hanover, Schaumburg-Lippe, Lippe-Detmold, Brunswick, Hesse-Nassau and the principality of Waldeck, south by the province of Hesse-Nassau, and west by the province of the Rhine and the Netherlands. Its area is 7,805 square miles. The chief cities are Münster, Bielefeld, Hamm, and Paderborn. The province in the south and northeast is generally mountainous. The northwest spreads out into extensive plains and belongs to the basin of the Ems; the northeast and a small part of the east to the basin of the Weser; the remainder, constituting the far larger portion of the whole, belongs to the basin of the Rhine. Livestock are numerous, particularly horned cattle, sheep and swine; the hams made from the latter have long been famous. The staple manufacture is linen, but that of iron is also very extensive. Mineral wealth is very great, especially coal and iron, mainly in the Ruhrgebiet. Other minerals mined include copper, lead, zinc and salt.

WESTPHALIA, Peace of, the treaty concluded in 1648 at Münster and Osnabrück, Westphalia, which ended the Thirty Years' War and established a new political system in Europe. After preliminaries had been settled at Hamburg toward the end of 1641 the actual negotiations were begun in 1644, at Osnabrück, between the empire, Sweden and the Protestant states, at Münster between the empire, France and other foreign powers. Two treaties were drawn up, one at Osnabrück, signed Aug. 6, 1648, and one at Münster, signed Oct. 24, 1648. Peace was restored with the signing of the latter. By this peace the religious and political state of Germany was settled. The sovereignty of the members of the empire was acknowledged. They received the right of concluding treaties among themselves and with foreign powers, only not against the emperor and empire. Their consent was made necessary to enable the emperor to put any of the members under the ban. The concessions that had been made to the Protestants since the religious peace in 1555 were confirmed. The form of public worship and the right to secularize ecclesiastical benefices were to return to what they were at the beginning of the so-called normal year 1624. The Calvinists (Reformirten) received equal rights with the adherents of the Augsburg Confession or the Lutherans. The elector-palatine had the palatinate of the Rhine and the electorate restored to him; Alsace was ceded to France; Sweden received western Pomerania, Bremen, Verden, Wismar and a sum equal to $3,750,000; Brandenburg, Mecklenburg, Hanover and Brunswick were compensated by the secularization of numerous ecclesiastical foundations. Germany lost altogether more than 40,000 square miles of territory and about 4,500,000 inhabitants. The independence of the United Provinces was recognized by Spain, and that of Switzerland by the empire. The solemn protest of Pope Innocent X against these terms, particularly in respect of the secularization of bishoprics and abbeys, etc., was not regarded; but the complete execution of the treaty was obstructed by many difficulties.

WESTPORT, town, Connecticut, in Fairfield County, on Long Island Sound at the mouth of the Saugatuck River and on the New York, New Haven and Hartford Railroad, and a federal highway, 4 miles east of Norwalk. The town has a total area of 22 square miles and contains three villages. Many artists and authors live here. Bedford High School has murals by John Steuart Curry. Four miles to the east, in the Great Swamp Fight of July 1637, the Pequot Indian War was ended. Westport's factory products are soap, disinfectants, embalming fluid, twine and cordage, woolen goods, and boats. It is governed by representative town meeting and three selectmen. Pop. (1940) 8,258.

WESTPORT, town, Massachusetts, in Bristol County; altitude 60 feet; on the Atlantic Ocean; 7 miles southeast of Fall River. Its Horseneck Beach is one of the finest beaches on the coast. There are manufactures of textiles, the first mill having been built in 1812. Pop. (1940) 4,134; (1950) 4,989.

WESTVIEW, town, British Columbia, Canada, about 100 miles north of Vancouver, incorporated 1942. It is the largest of three municipalities that are mainly residential and business adjuncts to Powell River the company town of the Powell River Paper Company whose local plant has a capacity of 1,000 tons of newsprint and 300 tons of pulp daily—the largest of its kind in Canada. There is a Dominion Government dock and airport. Pop. (1951) 3,507.

WESTVILLE, village, Illinois, in Vermilion County; altitude 671 feet; 132 miles south of Chicago; on Chicago and Eastern Illinois and the Big Four railroads. Industries include coal mining, an overalls factory and chick hatchery. Pop. (1940) 3,446; (1950) 3,196.

WESTVILLE, wĕst'vĭl, mining town, Nova Scotia, Canada, on the Middle River in Pictou County, 11 miles south of the town of Pictou and 130 miles northeast of Halifax via the Canadian National Railway. There are bus services to the neighboring towns of New Glasgow, Trenton and Stellarton. The town has four churches, three schools and two banks. Pop. (1941) 4,115; (1951) 4,261.

WESTWARD HO, one of the best known historical novels of Charles Kingsley, was begun in the spring of 1854 while Kingsley was living at Bideford and appeared the following year. The scene, laid chiefly in Bideford and at Plymouth and neighboring parts in the west of England, deals with the sea-faring English about the time of the Spanish Armada. The attempt is to picture the spirit of the English in their warfare against Spain. Historical characters, as Drake and Raleigh, are introduced, but the particular story is that of Amyas Leigh, his brother Frank and other members of the League of the "Rose of Torridge," so called from the beautiful heroine for whose hand these chivalrous and high-minded youths were rivals. Their individual rivalry was merged in the common cause against Spain, in which several, including Frank Leigh and the Rose, met their deaths. Finally Amyas, a stout-hearted young giant who had been particularly successful in vanquishing Spaniards, losing his eyesight, was obliged to pass the long remainder of his life in helplessness. The picture is a spirited one, though by no means in all respects historically accurate. The character and achievements of the English and the wiles and wickedness of the Spanish are painted with unstinting hands. As is usual in Kingsley's best-known works, like *Alton Locke* and *Hypatia,* even such chivalrous achievements do not constitute the best end of life. Only when Amyas Leigh, blind and helpless, can turn from an active to a spiritual life, is his highest happiness won.

WILLIAM T. BREWSTER.

WETASKIWIN, wĕ-tăs'kĭ-wĭn, city, Alberta, Canada, 42 miles south of Edmonton on the Canadian Pacific Calgary-Edmonton line at its junction with the line from Saskatoon. It is in an excellent mixed farming district which also yields timber, coal, natural gas and oil. A creamery, a flour mill, and a stock and poultry feed establishment are the principal local industries. There are five local grain elevators of a total capacity of 273,000 bushels. The town has churches, public and high schools, two weekly newspapers, the Wetaskiwin Community Hospital, a public library, a park and banks. The name is derived from a Cree word meaning "Hill of Peace" from a treaty which was concluded here between the Crees and Blackfeet. Pop. (1941) 2,318; (1951) 3,813.

WETHERALD, Agnes Ethelwyn (BEL THISTLEWAITE), Canadian poet: b. Rockwood, Ontario, April 26, 1857; d. Fenwick, Ontario, Canada, March 9, 1940. She was educated at Pickering College, Ontario. For some time she edited the women's department of the Toronto *Daily Globe,* and she was subsequently connected with the staff of the *Ladies' Home Journal.* Author *The House of Trees* (1896); *Tangled in Stars* (1902); *The Radiant Road* (1904); *The Last Robin* (1907); *Tree Top Morning* (1921); *Lyrics and Sonnets* (1931).

WETHERELL, wĕth'ĕr-ĕl, **Elizabeth.** See WARNER, SUSAN.

WETHERELL, Emma (Abbott), American soprano opera singer: b. Chicago, Ill., Dec. 9, 1849; d. Jan. 5, 1891. She first sang in public at the age of nine. Through the patronage and friendship of Clara Louise Kellogg she was enabled to go to New York in 1870, where she was engaged in the choir of the Church of the Divine Paternity, a number of whose members in 1872 contributed to send her abroad, and she studied for four years in Paris. She made her début in London in 1876 as Marguerite. For refusing to take the part of Violetta, in *La Traviata,* on moral grounds, her engagement was cancelled. In 1874 she was married to Eugene Wetherell. She made her first appearance in New York in 1877.

WETHERSFIELD, wĕth'ĕrz-fēld, town, Connecticut, in Hartford County; altitude 40 feet; 4 miles south of Hartford; on the New York, New Haven and Hartford Railroad. Once it had regular steamer connections with New York and intermediate ports but now is connected with Hartford and other nearby places by passenger and freight bus lines. It has manufactures of agricultural implements. Important industries of the town are the cultivation of seeds and packing and shipping of them. John Oldham, from Watertown, Mass., settled here with 10 men in 1634; the town was thus one of the first places in the state to be colonized. It has a famous elm tree 40 feet in circumference. The first church (Congregational) dates from 1761. A historic building is the Webb house where, in 1781, Washington and Rochambeau met. A state prison is located here. The educational institutions include public and private schools and a public library. Pop. (1950) 12,533.

WETMORE, Alexander, American biologist: b. North Freedom, Wisconsin, June 18, 1886. He was graduated from the University of Kansas in 1912, and later attended George Washington University and the University of Wisconsin. His

early positions were with the University of Kansas Museum, the Colorado Museum of Natural History, and with the Biological Survey of the United States Department of Agriculture. In 1924 he was superintendent of the National Zoological Park, Washington, D.C., and from 1925 to 1944 he served as assistant secretary, Smithsonian Institution, in charge of the United States National Museum. He has been secretary of the Smithsonian Institution since 1945.

His writings include *Observations on Birds of Argentina* (1926); *Fossil Birds of North America* (1931); *Systematic Classification for Birds of the World* (1940). He has also contributed numerous papers on ornithology and avian paleontology.

WETMORE, Edmund, American lawyer: b. Utica, New York, 1838; d. July 11, 1918. He was graduated at Harvard University in 1860, and at the Columbia University Law School in 1863. He was thereafter engaged in law practice in New York and became one of the most prominent lawyers in the city. He was senior member of the firm of Wetmore and Jenner. In 1900–1901 he was president of the American Bar Association. The degree LL.D. was conferred upon him by Yale University in 1906.

WETMORE, Elizabeth Bisland, American author: b. Fairfax Plantation, Louisiana, Feb. 11, 1861; d. near Charlottesville, Virginia, Jan. 6, 1929. She was privately educated, and was for a time on the staff of the New Orleans *Times-Democrat.* She later established herself in New York, became one of the editors of the *Cosmopolitan Magazine,* and was known as a magazine writer. She was married to C. W. Wetmore in 1891, and lived much in England.

Her work, published under her maiden name, includes *A Flying Trip Around the World* (1892); *A Candle of Understanding* (1902); *At the Sign of the Hobby Horse* (1908); *The Case of John Smith* (1916). She edited *Life and Letters of Lafcadio Hearn,* 2 vols. (1907); and *Japanese Letters of Lafcadio Hearn* (1910).

WETTERHORN, vĕt'ĕr-hôrn (peak of tempests), peak, Switzerland, one of the most striking of the Bernese Alps; has three summits —the west, called Jungfrau, 13,653 feet high; the middle, known as the Mittelhorn, 12,163 feet; and the east, the Rosenhorn, 12,114 feet. These were ascended first in 1844 and frequently since, the ascent being made from Grindelwald. The contrast between the bright fresh pastures and the black precipices and dazzling snow ridges of the Wetterhorn is particularly striking, making the valley of the Reichenbach a favorite resort of artists.

WEWOKA, wē-wō'kȧ, city, Oklahoma, Seminole County seat, 60 miles east-southeast of Oklahoma City. Agricultural products include corn, wheat, and cotton. Manufactures are gasoline, carbon black, petroleum products, brick, tile, oil well supplies, chemicals, and mattresses. Lake Wewoka, about 3 miles long, is nearby. It is popular as a recreation spot.

Wewoka was settled in 1902, incorporated as a town in 1907, and as a city in 1925. Pop. (1950) 6,747.

WEXFORD, wĕks'fĕrd, county, Ireland, in the province of Leinster, bounded north by the county of Wicklow, east by St. George's Channel, south by the Atlantic, west by the counties of Waterford, Kilkenny, and Carlow. Its greatest length, north and south, is about 60 miles; greatest breadth, east and west, 34 miles; area about 907 square miles. Its capital is the borough of the same name. Occupations of the inhabitants include livestock raising, agriculture, fishing, and dairy farming. Industries are also tanning, woolen milling, brewing, bacon and ham curing, and iron founding. Mt. Leinster, the highest point in the county, rises to 2,610 feet. Pop. (1946) 91,855.

WEXFORD, seaport and municipal borough, Ireland, capital of the county of Wexford, situated on the west shore, and in the upper part of Wexford Harbour. It is 93 miles due south of Dublin. The town, which is on the river Slaney, is irregularly built and the streets are narrow. Its chief manufactures are agricultural machinery and implements. The fisheries also employ many persons. It is a market town and exports grain, cattle, poultry, and butter. There are two newspapers in the town, the *Wexford Free Press,* and the *Wexford People.*

The name, Wexford, is a corruption of the Danish *Weis-Fiord,* meaning West Haven. Wexford was one of the main harbors used by the Norsemen in the 10th century. It was here also that the Anglo-Norman chiefs made their first invasion of Ireland in the 12th century. Wexford has always been a rebellious town; it not only fiercely resisted Cromwell in the 17th century, but in the 18th century it staged a revolution so successful that it is remembered in popular ballads. Pop. (1946) 12,296.

WEYBURN, wā'bĕrn, city, Province of Saskatchewan, Canada, 65 miles southeast of Regina, on the Canadian Pacific and Canadian National railways. It is a distributing point for a fertile mixed farming area. A flour mill and a creamery are the chief local industries. The Saskatchewan provincial mental hospital is located there. The town, which was incorporated in 1913, has five churches, three public schools, a collegiate institute, a public library, a municipal general hospital, a weekly newspaper, three banks, and an airport. Pop. (1951) 7,148.

WEYDEN, vī'dĕn, **Rogier van der** (French Roger de La Pasture), Flemish painter: b. Tournay, 1399?; d. Brussels, June 16, 1464. In 1426 he was apprenticed to learn painting, in 1432 became master in the painters' guild of Tournay, and in 1436 was chosen town artist of Brussels. His four works illustrating justice, executed for the golden chamber of the Hotel de Ville, were destroyed by fire in 1695. In 1499 he journeyed to Italy where he worked at Ferrara for Leonella d'Este, and painted also for the Medici and the Sforzas. He was the founder of the Brabant school. Among his principal extant works are a triptych in the Belvidere of Vienna; a triptych, *The Last Judgment;* and *The Descent from the Cross.*

WEYGAND, vā-gäN', **Maxime,** French army officer: b. Brussels, 1867. He trained at St. Cyr in 1888. He was chief of Foch's general staff, 1914–1923, and reorganized the Polish Army to resist the Bolshevik attack in 1920. In

1923 he was French high commissioner in Syria; chief of the army general staff in 1930, and vice president of the Higher Council of War in 1931. He was general inspector of the French Army from 1931 to 1935. General Weygand was commander in chief of all Allied forces, succeeding General Gamelin, at the time of the French collapse in the summer of 1940. He remained in France with the Vichy government until early September when he was dispatched to Africa to deal with the colonial situation. In November 1942, he was arrested by the Germans and held as hostage for Gen. Henri Giraud who had escaped from a German prison and joined the Allies. On May 5, 1945, with several other prominent Frenchmen, he was liberated from his Itter Castle prison in Austria by American troops. The investigating committee of the French High Court of Justice acquitted him of the charge of collaboration with the Nazis on May 6, 1948. Two days before the official announcement the committee's Communist members resigned in a body, enraged at the forthcoming exoneration of a general whose brilliant strategy in the Russo-Polish War of 1920 stalled the Soviet plan for Poland's conquest for 20 years.

WEYLER Y NICOLAU, wĕ'ĕ-lĕr ē nē-kô-lä'ŏŏ, **Valeriano,** MARQUIS OF TENERIFE, Spanish general: b. Palma, Island of Majorca, Dec. 17, 1838; d. Oct. 20, 1930. He was governor of the Philippines, 1888, and corps commander at Barcelona, 1892. He succeeded Martinez Campos as captain general of Cuba 1896 where his severe measures caused much adverse comment. Recalled in 1897, he was several times minister of war in Spanish Cabinets, and was president of the supreme war council in 1910. As captain general of Catalonia he suppressed the riots following the execution of Francisco Ferrer (q.v.) in 1909.

WEYMAN, wā'măn, **Stanley John,** English novelist: b. Ludlow, Shropshire, Aug. 7, 1855; d. Wales, April 10, 1928. He was educated at Shrewsbury School and Christ Church, Oxford, studied law, and was called to the bar in 1881. For nine years he practiced on the Oxford circuit and then began a literary career in 1890 by publishing a romance entitled *The House of the Wolf.* It was succeeded by *The New Rector* (1891) and *The Story of Francis Cludde* (1891), but it was his brilliant story, *A Gentleman of France* (1893), that first brought him into prominence and on his historical novels his reputation rests. His later works include *My Lady Rotha* (1894); *The Red Cockade* (1895); *The Man in Black* (1896); *Shrewsbury* (1897); *Under the Red Robe* (1899); *The Castle Inn* (1899); *Sophia* (1900); *Count Hannibal* (1901); *In Kings' Byways* (1905); *Wild Geese* (1908); *The Great House* (1919); *Ovington's Bank* (1922); *Traveller in the Fur Cloak* (1925); *Queen's Folly* (1925); and *The Lively Peggy* (1928). His tales are well constructed, with plenty of incident and adventure.

WEYMOUTH, town, Massachusetts, in Norfolk County; altitude 42 feet; on Boston Harbor; 12 miles southeast of Boston; on the New York, New Haven and Hartford Railroad. Weymouth contains a half dozen villages, each one a compact industrial center with its own residential section and post office. It has factories for boots and shoes, shoe counters, paper boxes and paper tubes. The educational institutions are grammar and primary schools; private schools; Tufts Library, which contains about 47,000 volumes; the Fogg Library; and a high school at Weymouth Center. The first permanent settlement was made in 1623 by Capt. Robert Gorges, but the place had been visited often before this time, notably in 1622 by Thomas Weston. The place was first called by the Indian name Wessagusset, until it was incorporated Sept. 2, 1635, when the present name was adopted. It is the second oldest settlement in the state. Abigail Adams, wife of President John Adams, was born here. Pop. (1950) 32,690.

WEYMOUTH AND MELCOMBE-REGIS, contiguous towns which form the municipal borough, England, in Dorsetshire, on a beautiful semicircular bay, seven miles south-southwest of Dorchester. Melcombe-Regis is separated from Weymouth by the small river Wey. It is well built; has two parish churches; several other places of worship, a general and an eye infirmary, townhall, reading room, Victoria jubilee hall, and libraries. There is a considerable coasting trade and an active traffic, passenger and other, with the Channel Islands and France. There are shipbuilding, sail-making and rope-making establishments. Portland stone is exported from the neighboring isle of Portland (q.v.). Both Weymouth and Melcombe-Regis, particularly the latter, from the beauty of the bay and its smooth, firm sands, attract numerous visitors. There is a fine esplanade about one mile in length. Pop. (1951) 37,097.

WEYPRECHT, vī'prĕĸt, **Karl,** German polar explorer: b. König, Odenwald, Germany, Sept. 8, 1838; d. Michelstadt, Hesse, March 29, 1881. He joined the Austrian Navy as a cadet in 1856, received his commission as an officer in 1861, and was promoted in 1866 for distinguished conduct in naval action off the island of Lissa in the Adriatic. He voyaged to the Orient, to America, and surveyed the coast of Dalmatia for two years. He explored the Barents Sea with Julius von Payer, Austrian polar explorer and painter, on an expedition which reached the high latitude of 78° 48′ N., 41° E. In 1873, again accompanied by von Payer, he commanded the expedition which discovered Franz Josef Land, the archipelago east of Spitsbergen and north of Novaya Zemlya. The expedition spent the winter and part of the summer of 1874 exploring the islands, and returned in the fall to Novaya Zemlya. At a meeting of German naturalists held at Graz in 1875, Weyprecht suggested that concerted scientific work at selected stations, undertaken by all interested nations, replace isolated excursions. His proposal, after being debated at the International Meteorological Congress and at two international polar conferences held at Hamburg and Berne, was accepted, and ten nations agreed to cooperate. Eventually all countries participated, and 15 expeditions were sent out.

Weyprecht's published works included *Die Metamorphosen des Polareises, Astronomische und geodätische Bestimmungen der österreichisch-ungarischen arktischen Expedition, Praktische Anleitung zur Beobachtung der Polarlichter und der magnetischen Erscheinungen im hohen Breiten.* Von Paver's account of the

Franz Josef Land expedition, *New Lands within the Arctic Circle,* has been translated. Consult A. W. Greeley, *Three Years of Arctic Service* (New York 1886).

WEYR, vīr, **Rudolf,** Austrian sculptor: b. Vienna, 22 March 1847. A pupil of Bauer and Cesar at the Vienna Academy, he won the Reichel prize with his *Samson and Delilah* (1870) and in 1878 was commissioned to execute the decorations of the Grillparzer monument. His reliefs and experiments in polychrome sculpture won for him a considerable reputation. Besides numerous decorations for the university and museum buildings at Vienna, his works include the *Triumphal Procession of Bacchus and Ariadne* for the pediment of the Burgtheatre, and the great fountain before the imperial palace. D. 1914.

WHALE. Dolphins, porpoises, and whales all belong to the order Cetacea. The classification is as follows:

Order *Cetacea.* Cetaceans.
  Suborder *Mystacoceti.* All cetaceans with whalebone.
    Family *Balaenidae.* Right whales.
    Family *Neobalaenidae.* Pygmy whales.
    Family *Rachianectidae.* Gray whales.
  Suborder *Odontoceti.* All cetaceans with teeth.
    Family *Physeteridae.* Sperm whales.
    Family *Ziphiidae.* Bottlenose whales.
    Family *Delphinidae.* Porpoises or dolphins.
    Family *Phatanistidae.* River porpoises.

The Cetacea are not fish but true mammals. They give birth to their young, nourish them with milk, and have warm blood. There are many indisputable evidences to show that whales once lived upon the land and walked on four legs like ordinary quadrupeds, but now they have assumed a completely aquatic life. In consequence, their body structure has been radically changed. Some of these modifications are listed below.

Externally the body has become long and streamlined. The fore limbs have been overlaid with tissue and blubber to form a paddle and have no articulations except at the shoulder; all other joints of the fore limb are stiffened. These «flippers» are used only in turning and ascending to the surface; not in forward movement. The hind limbs have completely disappeared, externally, and exist only as rudimentary bones buried deep within the body, some specimens showing vestiges of the pelvis, femur, and tibia. (Andrews records a «sport» humpback whale in which one of the hind limbs projected like a club for nearly two feet.) The flat propeller-like tail is horizontal and thus all Cetacea may be readily distinguished from fish in which the tail is verticle. The tail, called the «flukes,» is the sole means of propulsion. In some species there is a special erect longitudinal fold of skin, the dorsal «fin.» The skin of the Cetacea is comparatively thick and, except in the porpoises, very soft. It has lost the temperature-regulating sweat glands but there is a thick layer of fat or blubber directly beneath the skin which acts as an insulating blanket to prevent the animal's bodily heat from being absorbed by the water. The body temperature of a whale has been given as 31.1°, 36.6°, and 36.9° C. which is a little lower than that of a horse (38.2° C.) and a sheep (40.2° C.). Hair has entirely disappeared except for a few scattered bristles on the top of the head and chin. In all Cetacea the neck is short and immovable. The water pressure has not only greatly flattened the skull but also modified the soft parts of the face. Most important, is the migration of the nasal opening to the top of the head. In the baleen whales this is double; in toothed whales, single. The reason for this shifting of position is to allow the nostrils to be first exposed when the animal rises to the surface. The instant the whale's head appears, a blast of air is exhaled through the nostrils. This has been under pressure in the lungs, is highly heated and saturated with water vapor. It condenses upon striking the colder outer air forming a column of spray called the «spout.» This has given rise to the still widespread belief that a whale spouts out water through its nostrils. Since a whale is merely a land mammal that has become adapted for an aquatic existence, if water were taken into its lungs it would die as would a horse or cow. When the whale is beneath the surface, the nostrils are tightly closed, and the animal «holds its breath.» The length of time whales can remain submerged varies with the species. Andrews records 20 minutes for humpbacks; 50 minutes for blue whale; finback 23 minutes. All these species can doubtless remain under much longer if necessary. A bottlenose is reported to have stayed below for over an hour. The toothed whales descend to greater depths for their food and can remain submerged longer than baleen whales. The olfactory organs are so reduced that the whale has no sense of smell. The external ears have disappeared, and the auditory openings situated a few feet behind the eyes are very minute; about the size of knitting needles. The eyes are comparatively small with no nictitating membranes or lachrymal apparatus. Thus a whale cannot shed tears. The lungs are very large, and the diaphragm in Cetacea extends farther forward ventrially and farther backward dorsally than in land mammals. Thus the buoyant air is not confined to the forward part of the animal but much of it is disposed more caudally. This contributes to the balancing effect. Whales are subjected to great pressure when they make deep dives, and the sperm whale is known to go deeper than any other species except the bottlenose. Kellog (1940) records that in April 1932, the cable repair ship *All America* hoisted to the surface a dead sperm whale, 45 feet long, from a depth of 3,240 feet off the coast of Colombia. The cable was twisted about the lower jaw of the animal and an additional 180 feet was wrapped around the body. At such a depth the whale was subjected to a pressure of approximately 1,400 pounds per square inch.

Since none of the toothed whales chew their food, the dentition has degenerated. There is no differentiation into incisors, canines, premolars, and molars as in land mammals. The dentition consists of simple peglike teeth ideally suited for grasping slippery fish which form the greater part of the diet of most odontocetes. In the large killer whale the teeth are of the same type but much more powerful and are not only used for grasping fish but in tearing the flesh of seals and other whales. In the white porpoise (*Delphinapterus*) the teeth are few and weak and all in the front part of the jaws. The narwhal of the Arctic has no teeth in the lower jaw, but, in the upper, two maxillary teeth have developed as tusks. In the female these usually

grow to a length of 8 or 10 inches but remain unerupted. The male, however, has a straight, spirally-twisted tusk, 7 or 8 feet in length. In the ziphioid whales the teeth usually are reduced to two and are of no use in feeding. In one group of whales (Mystacoceti) the teeth are replaced with the so-called «whalebone.» This is not bone, but a series of horny plates or laminae, an epidermal growth which in reality is merely an exaggeration of the transverse ridges present in the mouths of land mammals. They hang in two parallel rows from the upper jaw. The inner edges are frayed out into hair-like bristles which are useful in straining out the minute crustaceans upon which these whales live. The animal feeds by swimming with open mouth into large shoals of crustacea. The water passes into the front of the mouth and out at the sides between the baleen plates. The food is left on the whalebone bristles. The tongue, which is a great fibrous mass weighing a ton, squeezes out the water when the mouth is closed. In order that a whale may feed beneath the surface without getting water into the breathing passages, an elongation of the arytenoid cartilages and the epiglottis fits into the soft passage between the nostrils and the trachea, entirely shutting off the nasal passages from the mouth. In the baleen whales the throat is small; in the toothed whales, large. The sperm is the only species with a throat large enough to swallow a human being. No man, however, could possibly live in a whale's stomach as he would be immediately smothered. A whale's stomach is complex and unlike that of any other mammal. The first, and largest, compartment, appears to be a dilatation of the oesophagus. The second is the true digestive part which contains the gastric glands. Then follow from one to five more compartments corresponding to the pyloric portion of the ordinary mammalian stomach. The intestinal canal is extremely long and narrow. In the odontocetes there is no caecum; the mystacotes have a caecum. The liver is small, not much divided, and has no gall bladder. In the reproductive system there are many adaptations to life in the water. Chief among these is the incomplete descent of the testes. They descend to the body wall in some cases but never appear externally. The penis is conical and pointed and normally is entirely retracted within a preputial sheath. In a large blue whale the penis was 9 feet 6 inches in length. In the female the mammary gland teats are only three or four inches in length. They are concealed in slits on either side of the vulva but are protruded during nursing. By means of a special compressor muscle the milk is injected into the calf's mouth. The milk itself looks exactly like cow's milk.

The blue whale, or sulphurbottom, is not only the biggest animal existing today on the earth or in its waters, but so far as is known is the largest animal that has ever existed. It exceeds in size and weight even the greatest dinosaurs. The three largest blue whales recorded from South Georgia Island in the South Atlantic, according to C. A. Larson, were 103 feet, 108 feet, and 111 feet in length measured on a straight line. Undoubtedly the principal reason why whales grow to such enormous size is because their bodies are supported by the water in which they live. A bird is limited to the weight its wings can bear up in the air; a land mammal to what its legs can hold off the ground. The 111 foot blue whale must have weighed about 90 tons. In 1903 Dr. Frederic A. Lucas weighed in sections a blue whale taken at Newfoundland. The animal was 78 feet long and 35 feet around the shoulders. The total weight was 63 tons; flesh 40 tons; blubber 8 tons; blood, viscera and baleen 7 tons; bones 8 tons.

The size of the young at birth varies with the species and size of the mother. Andrews records a 25-foot foetus from an 80 foot blue whale. The baby weighed about 8 tons. Off the Japan coast a 32-foot sperm whale contained a foetus 14 feet 8 inches long. In Alaska a 65-foot finback gave birth to a 22 foot baby as she was being hauled out of the water. The great size of the calves is due, of course, to the fact that whales live in a supporting medium. It is impossible to determine how long whales live. By examining the ovaries and counting the scars on the outer surface, or more precisely the number of *corpora lutea,* an idea of the age of the females can be obtained. A. H. Laurie, of the *Discovery* expeditions to the South Atlantic, concludes that the blue whales there breed at the rate of once every two years at best; the oldest females were 30 years of age; the young nurse for 6 to 7 months. The blue whales were physically mature at from 10 to 11 years; fin whales, at 6 to 8 years.

A short diagnosis of the principal species of whales follows.

Humpbacks (*Megaptera nodosa*).—The humpback is in many respects the most remarkable of all whales. It reaches a length of about 55 feet. The anterior part of the body is very massive, but the posterior quite slender and at the same time so irregularly shaped and so awkwardly joined to the thorax that the animal appears misshapen. This effect is heightened by the dorsal fin, which is low and thick. Not less striking are the immense crenate-margined pectoral fins, like the wings of a bird, and about one third as long as the body. The broad abdominal ridges nearest the median line join below the throat, forming a chinlike protuberance. Humpbacks are infested by large barnacles of the genus *Coronula,* which fasten on the head, fins, flukes, and abdominal ridges. Where they settle on the black skin but are afterward rubbed off, or otherwise got rid of, they leave behind distinct white marks, in the form of disks, circles, crescents, etc., which add to the singular appearance of these whales. Fastened to the large barnacles, are often bunches of stalked barnacles, genus *Otion,* which hang down like fringes on the fins. Humpbacks occur in all seas, from the Arctic to the Antarctic. They are very irregular in their movements and indulge in all manner of uncouth actions. When they dive or sound they throw the flukes out of the water. Like other cetaceans they engage in seasonal migrations northward and southward. They feed chiefly on a small shrimp.

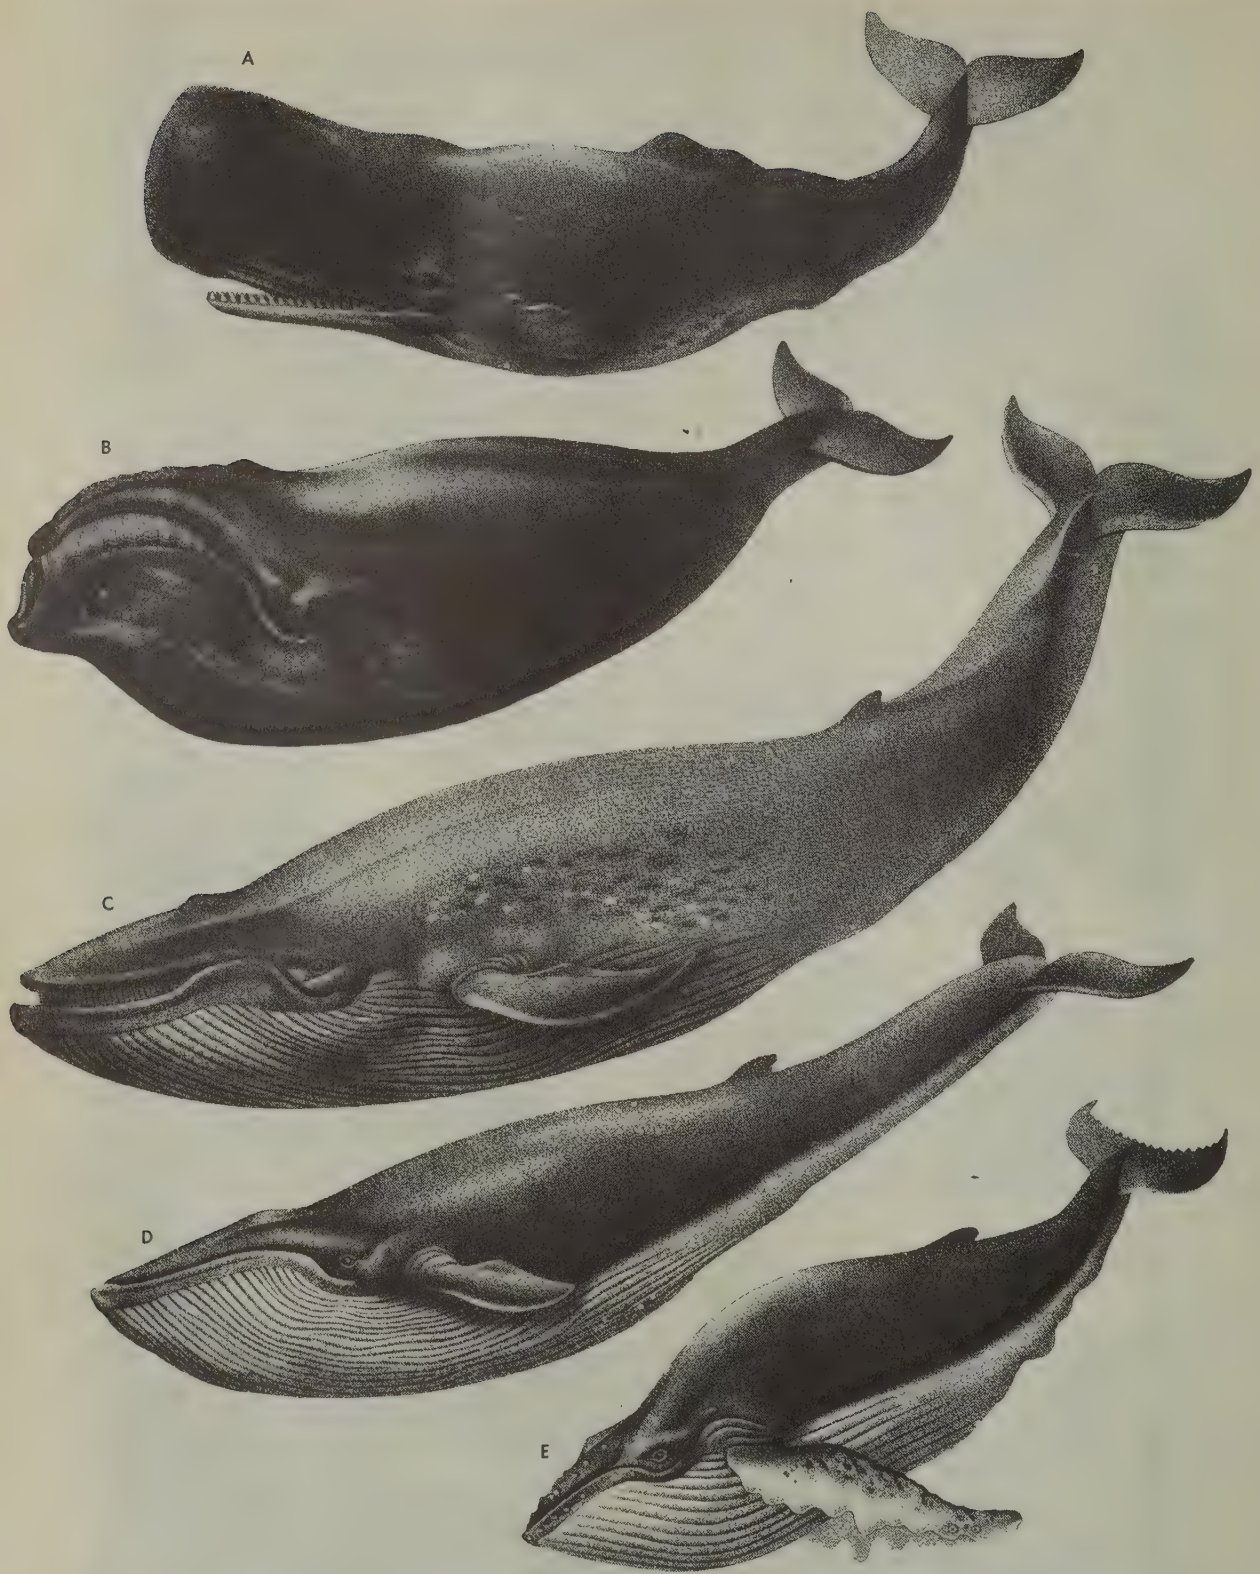
Blue Whale, or Sulphurbottom (*Balaenoptera musculus*).—The blue whale has a massive head and broad snout, and the body tapers gradually to the flukes. The dorsal fin is falcate and less than a foot long, and is situated at a point a little more than three-fourths the distance from the top of the snout to the notch of the flukes. The pectoral fins are falcate and about seven and one-half feet long, from the axilla. In color the blue whale is gray, nearly

WHALE

D. Richard Statile

Top: Tons of whale are on the other end of this towline from the "killer" boat. *Center left:* Helicopters are being used to spot whales. *Center right:* This whale carcass is being hauled up the ramp on the "factory" ship to be dismembered. Inside the open mouth, a curious interior structure is visible. The hair-like bristles, or baleen, serve to "strain" the crustacean food the whale obtains by swimming with its mouth open. *Bottom:* A blue whale is cut up; about an hour after it comes aboard, the whole animal has gone down, piecemeal, to the boilers where the oil is taken out of the blubber.

WHALE



Important oil whales: A, the sperm whale yields an average of 90 barrels of oil for industrial uses. Males grow up to 70 feet in length. B, the right whale is now protected by restrictions on whaling. The whale got its peculiar name because it was just "right" for the whalers, easy to kill and full of oil. C, the blue whale is one of the largest living creatures. Some reach 100 feet in length, and yield as much as 150 barrels of oil. D, finback whales grow to an average length of 65 feet, and yield something like 70 barrels. It's the most plentiful remaining species. E, the humpback whale, is the most playful of all. It may run to 55 feet and yield up to 60 barrels of oil. Only 1,250 may be killed each year.

By special permission. Drawings by Rudolf Freund. From "LIFE." © 1952

uniform on the head, but mottled on the back and sides. On the belly are numerous white spots. The pectoral fins are gray above and white below, the flukes gray on both sides and the dorsal fin also gray, sometimes with a whitish center. The abdominal ridges number 62 to 88. The whalebone is about three feet long, broad at the base and black in color, both plates and bristles. These huge whales feed exclusively on small crustaceans, the species in the North Atlantic being the thysanopod *Euphausia inermis*.

Common Finback (*Balaenoptera physalus*).—This is the most commonly observed and best known of the finbacks. In size it ranks next to the blue whale. The form is exceedingly attenuated. Adult individuals reach an average length of 65 feet. The head is narrow anteriorly. The dorsal fin exceeds a foot in height. The pectoral fins are small, somewhat triangular, and about five feet long, from the axilla. This whale is gray on the back and upper surfaces of the pectoral fins and flukes and white on the belly and the under surfaces of the pectoral fins and flukes. The whalebone as a whole is gray, striped longitudinally with white, but at the anterior end of the jaw on the right side the whalebone is all white. The outside of the right lower jaw is also white. These parts are dark on the left side. This singular asymmetry of coloration is peculiar to, and characteristic of, the species. The common finback feeds on various kinds of small fish and *Euphausia*.

The large whales which strand on the east coast of the United States are almost invariably of this species. When swimming or rising to spout, this whale, like the blue whale, shows the top of the head and back and the dorsal fin, but nothing beyond. The flukes are not thrown out of the water when it dives or sounds.

Little Piked Whale, or Lesser Finner (*Balaenoptera acuto-rostrata*).—This is the smallest of the finbacks and is not sought for by whalers. The form is thickset like that of a porpoise and the head pointed. When adult, it is about 25 feet long, and the maximum length is about 28 feet. The dorsal fin is larger than in any of the other finbacks and is situated farther forward, or at a point only about two-thirds the distance from the tip of the snout to the notch of the flukes. It is very dark gray or blackish on the back and sides and white on the belly, a little clouded with gray. The pectoral fins are blackish above, with a broad crossband of white near the middle; below they are white. The flukes are blackish above and whitish below. In this species the abdominal ridges are very numerous and narrow. The whalebone is very short and entirely white. The little piked whale feeds upon fish.

California Gray Whale, Grayback or Devilfish (*Rhachianectes glaucus*).—This remarkable whale is found only in the North Pacific. When full grown it has a length of about 50 feet. It is a restless and sagacious animal, and when wounded frequently attacks the boats sent out for its capture. In earlier days it was found abundantly in the winter months in the lagoons and bays of Lower California whither it repaired to breed. It is fond of playing in the surf and approaches close inshore to indulge in this recreation without fear of stranding. The gray whale is found as far northward as Bering Sea and occurs also on the coast of Korea, but has no counterpart in other seas.

Greenland Right Whale, Arctic Right Whale, or Bowhead (*Balaena mysticetus*).—This Arctic right whale, or bowhead, as it is called by American whalers, is most remarkable in appearance. The snout is narrow and arched like a bow. From the roof of the mouth depends the extraordinary, narrow black whalebone, which may be 12 feet long or even longer. This whalebone is enclosed and protected by the immense oblong lower lip, the curved upper edges of which fit against the side of the upper jaw when the mouth is shut. The back is without a fin, while the pectorals are short and broad. There are no ridges or furrows on the belly. Adults reach a length of about 60 feet. The bowhead rarely or never leaves the Arctic ice, but like other whales it migrates northward and southward with the changes of the seasons. On the east coast of America it is never seen as far south as the southern extremity of Greenland, though there is a tradition that at the time of the discovery of the country it ranged as far south as the Strait of Belle Isle in winter. It occurs in the Arctic Ocean north of Alaska and ranges southward into Bering Sea. Individuals are believed to pass back and forth through the channels between the islands north of the continent from the eastern to western side. The bowhead feeds chiefly on small pteropod mollusks and crustaceans which occur in vast multitudes in the Arctic Ocean.

Atlantic Right Whale (*Balaena glacialis*).—This whale resembles the bowhead in general appearance, but the head is smaller and less arched, and the whalebone shorter, or only about seven feet long. Near the end of the snout is a low rounded protuberance, called the «bonnet» by whalers. This bonnet is covered with barnacles, which are not found adhering to the bowhead. It is usually entirely black, but some individuals have been reported as whitish or grayish on the throat and breast. When full-grown it reaches a length of about 55 feet. Like the bowhead it feeds upon crustaceans and pteropod mollusks. There is every reason to believe that this whale was the object of pursuit of the earliest whale fishers among the Basques in the Bay of Biscay in the Middle Ages. It was the species on which the American colonial shore whale-fishery was based. The Atlantic right whale, like the bowhead, feeds upon pteropod mollusks and crustaceans.

Pygmy Right Whale of New Zealand (*Neobalaena marginata*).—This is a remarkable little whale, resembling the large right whales, but reaching a length of only about 20 feet. It has a small dorsal fin, but no abdominal ridges or furrows. The whalebone is long and white. In color the whale is black, with a line of white along the belly. It has many osteological peculiarities, among which one of the most striking is the flatness and breadth of the ribs, of which there are 17 pairs. The lumbar vertebrae are only two in number. Little is known of the habits of this whale.

Sperm Whale (*Physeter macrocephalus*).—This whale belongs to the Odontoceti, or toothed whales. But one species of sperm whale is known. When full-grown the male reaches a length of 60 to 70 feet, but the female is much smaller. The head is of immense size, and is shaped like an elongated wedge with the base uppermost, and the edges and free end rounded. The blowhole is single and situated at the end

of the snout on the left side. The lower jaw is very narrow and much shorter than the upper, and the two sides are joined together anteriorly for about one-half the length. In it are implanted about 44 large conical teeth which fit into pits in the upper jaw when the mouth is closed. There are no teeth in the upper jaw. The back is without a fin, but is raised into a number of low irregular humps posteriorly. The pectoral fins are broad and about six feet long. In color the sperm whale is blackish above and somewhat mottled with gray below. It occurs in all seas except the Arctic and Antarctic, but is essentially an animal of the tropics. The herds or schools are diversified in character, some comprising only young bulls; others, females and young led by an old bull. At times old bulls are encountered wandering singly or in small groups. These old males are ill-tempered and pugnacious, and do not hesitate to attack the boats of the whalers. The sperm whale feeds upon large cuttlefish, which its great strength and powerful under-teeth are supposed to enable it to dislodge from their rocky retreats at the bottom of the sea.

Bottlenosed Whales, or Beaked Whales (family *Ziphiidae*).—This family comprises four or five genera of small whales, none of them exceeding about 30 feet in length. Several species of each genus have been described. Like the sperm whale, they belong to the suborder Odontoceti, or the toothed whales. They never have, however, more than four teeth regularly implanted in the jaws, but some species have numerous minute, rudimentary teeth imbedded in the lips. The head of all the forms, at least in the young, is pointed, the dorsal fin low and placed far back toward the flukes, the pectoral fins narrow and of moderate length. In the bottlenose whale of the North Atlantic (*Hyperoödon rostratum*) the forehead gradually increases in size with age, until it is sharply marked off from the narrow beak, like the shoulder of a bottle. The species congregates in large herds and is eagerly sought by whalers for its oil. The beaked whales of the remaining genera *Mesoplodon, Berardius,* and *Ziphius,* are far less abundant. They travel in pairs. *Hyperoödon* is peculiar to the North Atlantic; *Berardius* occurs only in Bering Sea and about New Zealand and Japan, while *Mesoplodon* and *Ziphius* appear to be cosmopolitan genera. The beaked whales subsist upon cuttlefish.

ROY CHAPMAN ANDREWS,
Honorary Director, The American Museum of Natural History.

WHALE-BIRD. See FULMAR.

WHALE-HEAD, a stork. See BALAENICEPS.

WHALE-LOUSE, any of various small crustaceans parasitic on whales. (See FISH-LICE). These crustaceans have a rudimentary abdomen, and have the limbs of the first joint of the thorax or chest inserted beneath the throat. The body is flattened and of oval shape and the legs are all prehensile. They burrow deeply into the skin of their hosts.

WHALE OIL. Oil obtained from a whale's blubber by trying out. (See WHALE). It is light yellow to dark brown. The variety known as sperm oil comes from the head of the sperm whale. The use of whale oil appears to be of ancient origin. It was doubtless first obtained from whales accidentally stranded on the shores, a more frequent occurrence during the early abundance of the cetaceans than at present, when their numbers have been so greatly reduced by excessive fisheries. As the demand for the oil increased beyond the supply available from stranded whales, individuals sighted from the shore were attacked and beached. Owing to the frailty of the boats and equipment, this was a more daring attempt than might be supposed. Just prior to the Revolutionary War there were 183 American vessels in the right whale fishery of the North Atlantic waters and 125 were engaged in cruising for sperm whales from Newfoundland to the coast of Brazil. The Revolutionary War and the War of 1812 interfered with the fisheries; but during the period of peace following 1815 they increased greatly in extent until 1846, when the fleet numbered 678 ships and barks, 35 brigs and 22 schooners, a total of 735 vessels, with an aggregate tonnage of 233,189 tons and a value of $21,075,000, exclusive of outfits and supplies. The entire capital invested in the fishery and its associated industries at that time approximated $40,000,000 and 40,000 persons derived from it their chief support. During the same year the whaling fleet of all Europe numbered but 230 vessels. Large whales have been known to yield 250 barrels of 32 gallons, but probably an average for a large whale was 75 barrels and down to 12 barrels for a small bottlenose whale. The crude value of the American catch from 1840 to 1860 averaged about $8,000,000 annually. The greatest value was in 1854, when 2,315,924 gallons of sperm oil worth $1.48¾ per gallon, 10,074,866 gallons of whale oil worth 59⅝ cents per gallon and 3,445,200 pounds of whalebone worth 39⅕ cents per pound were secured, the total value being $10,802,594. In the preceding year, 1853, the total product was 3,246,925 gallons of sperm oil, 8,193,591 gallons of whale oil and 5,652,300 pounds of whalebone, the whole valued at $10,766,521. Sperm oil and whale oil then served nearly all the diversified uses for which oil was required, the chief exception being leather-dressing, for which neatsfoot and cod oils were largely employed. The principal uses were as illuminant, lubricator, in cordage manufacture, screw-cutting and steel-tempering. The streets of the principal cities were lighted with the oil and theaters and public buildings were lighted with gas made from the oil settlings.

In 1902 the whaling fleet of the United States consisted of eight steamers, 18 barques and brigs and 12 schooners, aggregating 8,366 tons. Of these, 11 barques and 10 schooners were sperm whale fishing in the Atlantic Ocean, eight steamers in the Arctic, six barques in Okhotsk Sea and off the coast of Japan, two schooners in Hudson Bay and one brig at Desolation Island. The total whale oil product of the world in 1902 approximated 3,000,000 gallons, of which 750,000 gallons were produced by the United States fisheries, 900,000 by those of Norway and the remainder by Scotland, Russia, Japan, Newfoundland, etc. Since that date the product has steadily reduced.

WHALEBACK STEAMSHIP. See STEAM VESSELS.

WHALEBONE. See WHALING.

WHALING, or the pursuit of whales as an industry, existed in the North Atlantic Ocean at

a remote period. There are obscure references to it in Norwegian and English history as early as the beginning of the 10th century. In the 11th century the Basques pursued the North Atlantic right whale, or black whale (*Balaena glacialis*), with harpoons, in open boats. It is even asserted that they crossed the Atlantic in pursuit of their quarry before the time of Columbus, but this has not been substantiated. Certain it is that they visited Newfoundland immediately after the discovery of America and captured the same species of right whale in those waters. They are supposed also to have first seen the Arctic right whale, or bowhead (*Balaena mysticetus*), in the Strait of Belle Isle. In 1607 Henry Hudson encountered the bowhead in the vicinity of Spitzbergen. The Spitzbergen fishery developed rapidly on account of the large amount of oil yielded by this species and was extensively engaged in by various European nations, especially the Dutch, who in 1680 employed 260 vessels and about 14,000 men in the industry. During the decade beginning 1679, the Dutch took an average of about 1,000 whales annually. As the bowheads decreased about Spitzbergen, they were sought for to the westward, and in 1719 a Dutch vessel first entered Davis Strait. This fishery was developed chiefly by the British, Danes and Americans; in 1789 there were 255 British vessels engaged in it. The first American vessel visited Davis Strait in 1732. The number increased rapidly, and at the height of the fishery, just before the Revolutionary War, Massachusetts alone sent 183 vessels to the strait.

About 1670, the American colonists succeeded in establishing a boat shore-fishery for the Atlantic right whale, which in those days was abundant on the coast, especially off Long Island and in Delaware Bay, and was well known from a much earlier date through stranded individuals. Later the colonists pursued the whales in sailing vessels farther from shore and in the Gulf of Saint Lawrence, but finally turned their attention to the Arctic right whale, or bowhead, in Davis Strait, as already mentioned.

About 1712 the first sperm whale was captured at sea by a Nantucket whaler. This fishery rapidly rose in importance and was pursued in all the oceans of the globe, especially by the Americans. The British did not apply themselves to it until 1775, but in 1790 a British whaling vessel rounded Cape Horn and opened up the Pacific fishery, which immediately grew to enormous proportions, and was at its height in 1837. The American whaling fleet in 1839 comprised 555 vessels, of which the majority were engaged in the Pacific sperm whale fishery. In 1847 the number rose to 594, while the foreign whaling fleet numbered 230 vessels. The size of the American fleet reached its maximum in 1846, when 729 vessels were employed.

While a large part of the American fleet was engaged in the pursuit of the sperm whale, the remaining vessels were chiefly employed in hunting right whales, especially in the North Pacific. As the sperm whale fishery declined, this branch increased in importance. In 1835 the famous Kadiak ground was discovered. A new epoch opened in 1843 when bowhead whales were first taken off the Kamchatka Coast. In 1848 the first vessel passed through Bering Strait to pursue these large whales in the Arctic Ocean. The fishery in the North Pacific and adjoining Arctic was at its height in 1852, when 278 vessels were employed. In 1866 the first American steam whaling vessel was brought into use, and in 1880 two steamers were added to the Pacific-Arctic fleet.

The introduction of mineral oils for illuminating and other purposes and the decrease in the abundance of whales gradually broke down the fishery for right and sperm whales and at the present time the number of vessels engaged in the industry is negligible. A few sailing vessels still pursue the sperm whale, but in 1902 only five British vessels (steamers from Dundee, Scotland) entered Davis Strait in pursuit of the bowhead. The American whaling fleet in 1902 comprised 38 vessels, including eight steamers engaged in the Pacific-Arctic bowhead fishery. Of the remaining 30 sailing vessels, 21 engaged in sperm whaling in the Atlantic; six visited Okhotsk Sea and the coast of Japan, two entered Hudson Bay and one remained about Desolation Island. In recent years about 250 whalers operate in Antarctic waters. The annual catch is about 30,000 whales.

The humpback whale was always pursued to some extent by right whale whalers, but the finbacks and sulphurbottoms, besides furnishing a relatively small amount of oil, were too swift to be attacked successfully with hand harpoons. About 1865, Svend Foyn, a Norwegian fisherman, invented a method of shooting them with a combined harpoon and bomb fired from a swivel gun mounted at the bow of a small steamer and for 30 years large numbers of sulphurbottoms, finbacks, and humpbacks were killed annually at stations established on the coast of Finmark. Later the same method was employed at Iceland, the Faröe and Shetland Islands and also about Japan. In 1898 this mode of whaling was introduced into Newfoundland, where a number of sulphurbottoms, common finbacks and humpbacks are still killed annually.

A considerable number of common finbacks and humpbacks have been killed in Massachusetts Bay and the Gulf of Maine by means of explosive bombs attached to a special form of hand harpoon, called a «darting gun.» A boat-fishery of limited extent has been in existence for many years on the coast of California. It has for its object the capture of the California gray whale, and the humpback, which are killed by harpoons fired from a swivel gun mounted at the bow of a whale boat. Similar boat fisheries exist on the coast of New Zealand, in the West Indies and in other parts of the world.

Pelagic whalers capable of processing animals at sea have become extremely efficient, not only in treating the whales taken, but also in capturing them. The catch of the large blue whale (*Balaenoptera musculus*) has been estimated to reach 12,000 a year. Fear has consequently been expressed that many species face extermination, especially as the great mammals are not prolific. The females give birth usually to only one offspring once every two years or so. The government of the Falkland Islands has accordingly for some time prohibited the capture of right whales, restricted the taking of humpback whales to owners of permits, and has prohibited the killing of cow whales and of calves altogether.

WHALLEY, hwŏl'ĭ, **Edward,** English regicide: b. England, about 1616; d. Hadley, Mass., about 1675. He was in trade, probably that of woolen-draper, at the outbreak of the

Civil War, when he enlisted for Parliament. In 1643 he became a major in Cromwell's regiment. After Charles I was seized, Whalley was ordered to take charge of the king and in that post displayed much tact. On the Restoration he did not obey the summons of surrender of the king's judges and was therefore excluded from the indemnity. He sailed with William Goffe (q.v.) for New England, and resided for a time in Cambridge. When the act of indemnity reached Boston in November and the town council met (February 1661) to consult regarding the refugees, he went with Goffe to New Haven. He was associated with Goffe in the subsequent wanderings and concealments which have lent such interest to their history.

WHARTON, Anne Hollingsworth, American author: b. Southampton Furnace, Pa., Dec. 15, 1845; d. Philadelphia, Pa., July 29, 1928. She wrote mainly upon colonial themes and among her books are: *The Wharton Family* (1880); *Through Colonial Doorways* (1893); *Colonial Days and Dames* (1894); *A Last Century Maid* (1895); *Martha Washington: A Biography* (1897); *Heirlooms in Miniature* (1897); *Salons Colonial and Republican* (1900); *Social Life in the Early Republic* (1902); *An English Honeymoon* (1908); *In Chateau Land* (1911); *English Ancestral Homes of Noted Americans* (1915); *In Old Pennsylvania Towns* (1920).

WHARTON, Edith Newbold (nee **Jones),** American novelist: b. New York City, Jan. 24, 1862; d. Saint-Brice-sous-Forêt, France, Aug. 11, 1937. She was a descendant of wealthy, socially prominent New York families and was privately educated. After making a formal debut, in 1885 she married Edward Wharton of Boston. During the remainder of her life she lived in the United States and France, maintaining residences in both countries.

Mrs. Wharton began writing as a therapeutic measure and as a means of occupying her free time, when her husband was suffering from a mental illness. In the 1890's she published her first short stories in *Scribner's* magazine and for over 30 years was classed among the better popular American writers. In 1924, she was the first woman ever to receive an honorary degree from Yale University. Many details of her career can be found in her autobiography, *A Backward Glance* (1934). She continued writing until her death, and an unfinished novel, *The Buccaneers,* was published posthumously in 1938.

Much of her writing was concerned with the closed, wealthy New York society which she had known as a child. Her first very successful novel, *The House of Mirth* (1905), was the story of a young woman without money who tried to maintain her status in the high social group to which she was born. The setting of her most famous story, *Ethan Frome* (1911), was the region around Lenox, Mass., where Mrs. Wharton often spent her summers. The unhappy love affair of Mattie Silver and Ethan Frome was soon recognized as an American classic. Her most successful use of the New York scene was in *The Age of Innocence* (1920) which was given the Pulitzer Prize in 1921. The characters of Newland Archer and Ellen Olenska expressed the unbreakable moral code which ruled Victorian society

The drama in the narratives, especially in the endings, is evidenced by the fact that three of the novels have been adapted for the stage with great success: *The Age of Innocence, Ethan Frome,* and *The Old Maid* (winner of the Pulitzer Prize for drama in 1935). Mrs. Wharton had a rich, colorful style, frequently satiric, and full of humor. Her friendships with the American author, Henry James, and Paul Bourget, the French novelist, had a great effect upon her work, as she frequently discussed it and read parts aloud to these friends before publication. With more than 35 volumes of work to her credit, some of the best remembered are: *The Valley of Decision* (1902); *The Reef* (1912); *Summer* (1917); *The Marne* (1918); *A Son at the Front* (1923); *The Children* (1928); *Hudson River Bracketed* (1929); and *Ghosts* (short stories, 1937). See also Age of Innocence; American Literature; Novel—*Modern* (American).

WHARTON, Francis, American jurist: b. Philadelphia, Pa., March 7, 1820; d. Washington, D.C., Feb. 21, 1889. He was graduated at Yale in 1839, studied law, and was admitted to the bar in 1843. He was professor of logic and rhetoric in Kenyon College, Ohio, 1856–1863; in 1863 took orders in the Episcopal Church and became rector of Saint Paul's, Brookline, Mass. In 1866 he became a professor in the Episcopal Divinity School at Cambridge, Mass., and also held the chair of international law in the Boston Law School. In 1885 he was appointed counsel for the State Department at Washington and under a resolution of Congress (1888). His best known work is a *Treatise on the Criminal Law of the United States* (1846), which is accepted as a standard and has passed through many editions. He edited *A Digest of the International Law of the United States,* 3 vols., in 1886.

WHARTON, Philip, Duke of, English politician: b. December 1698; d. Tarragona, Spain, May 31, 1731. At 16 he married clandestinely and in 1716 traveled on the Continent and visited the Pretender at Avignon. That prince, gratified by his attentions, gave him the title of Duke of Northumberland. About the end of 1716 he returned to England and thence to Ireland, where he possessed a peerage, and was allowed, although not yet 19, to take his seat in the Irish House of Peers. He obtained a British dukedom in 1718 and on attaining his majority made his appearance in the English Parliament, where he distinguished himself as the defender of Bishop Atterbury.

WHARTON, Thomas, American journalist: b. Philadelphia, Pa., Aug. 1, 1859; d. there, April 6, 1896. He was graduated from the University of Pennsylvania in 1879 and joined the editorial staff of the Philadelphia *Times* in 1888. His short story *Bobbo* enjoyed wide popularity and was dramatized and successfully played in England.

WHARTON, N.J. (formerly Port Oram), borough in Morris County; on the Rockaway River; 23m. W. of Paterson; on the Delaware, Lackawanna and Western, and Central of New Jersey (the Wharton and Northern) railroads. The borough is located in an old iron-mining

region. Manufactures include silks, paper and gunpowder. Near by is Lake Hopatcong, a popular summer resort. Pop. (1940) 3,854; (1950) 3,862.

WHARVES AND WHARF CONSTRUCTION. Definitions.—The words wharf, pier, quay, jetty, and dock frequently are used indiscriminately. Authorities generally agree that wharf is a general term for a structure at the water's edge in a port or harbor, which serves to secure a ship, vessel, or boat in place while it is receiving or discharging passengers, cargo, or both. A pier is a wharf which projects more or less perpendicularly from the shore line permitting vessels to be berthed or secured on either side; while a quay is a wharf constructed along the shore line offering only one side for the berthing of vessels. Jetty is an alternate word for pier which is used in England, but in the United States the word jetty is applied to a structure which may have the same form as a pier, but serves the purpose of protecting a harbor entrance or other shore line feature from erosion, deposition, or storm waves rather than providing a landing space for vessels. Dock properly connotes an enclosed body of water. A wet dock usually is equipped with gates or locks through which vessels may enter or leave and while within are protected from tidal fluctuations. A dry dock is also equipped with gates and may be pumped dry for the purpose of accomplishing repairs to vessels therein.

Historical.—There is evidence of harbors having been constructed in the Mediterranean Sea as early as 3500 B.C. Among the earliest navigators were the Cretans and the island of Crete contained a harbor at Mesara prior to 3000 B.C. The large port of Pharos was built by the Cretans shortly after 2000 B.C. The remains of a great breakwater can be traced at the latter port and there are rough stone blocks which appear to have formed a quay nearly 50 feet wide. The Phoenicians were engaged in sea trade prior to 1250 B.C. and their earliest harbor was at Saida, although no physical traces remain. At Tyre, however, there are remains of breakwaters and quays constructed of hewn stone joined together with iron dowels. Remains of a similar nature have been found at Carthage. Alexander the Great founded the port of Alexandria and a part of it consisted of Pharos, originally an island, which was joined to the mainland by a causeway. The ancient Greeks built a number of harbors. The structures involved were generally of stone masonry joined together with iron rods and clamps which in turn were secured with melted lead. Foundations below water were built by dumping broken stone into the water forming mounds upon which the structures projecting above water were built. The Romans were the first to unwater a site on an extensive scale for the construction of harbor works. They also employed driven piles to support masonry walls. Unwatering was accomplished by use of piles, planks, and timbers chained together in the form of double walls, between which a filling of clay and weeds was rammed to form a temporary watertight structure surrounding the area which was to contain the permanent work. The water from the area was pumped out by the means then available, such as water wheels. The foundations for the permanent work were then leveled or excavated to firm foundations, or piles were driven. The whole procedure was like modern cofferdam construction methods and differences were mainly in materials and equipment then available. The Romans also used a hydraulic cement which possessed strength and durability comparable to modern portland cement. A common form of Roman construction employed for piers and quays was of masonry with about one half the length of the structure carried to foundation levels at sea bottom with circular arch spans between the foundation sections, much like a stone arch bridge of short multiple spans. In some cases, a pier would consist of two such structures built parallel joined by an arch deck in the transverse direction, and with spans staggered to reduce wave action. Many of these ancient structures were monumental in character beyond anything which has been built since. After the Romans, practically no harbor construction was done until the 18th century. Among the early works of this latter period, which started the modern era, were docks near Dunkerque, the then most important port in France. Walls for the locks forming the entrance to the docks and quay walls were founded on timber piles driven into the natural sand. Timber beams were fastened to the pile heads and floored over with wooden planks. Walls were built on these floors with stone and mortar and iron dowels.

Basic Requirements and General Forms of Construction.—A wharf must provide a place in a harbor or port to which a vessel may be brought and secured in ample depths of water and safe against breaking adrift due to storms and waves; and at which place passengers and cargo may be received or discharged from or to a firm floor contiguous to and at a height convenient to the decks or openings to the hold of the vessel. The floor must permit the handling and temporary storage of cargo and the transfer of passengers and cargo from and to any one of the several forms of land transportation. For modern vessels, the edge of the wharf floor or deck must be vertically above or slightly overhang the full depth of water required by the vessels and the length of the wharf must be approximately equal to the length of the vessel, to provide safe mooring facilities. The width of the wharf will be governed by the handling and storage requirements of the cargo, the character and number of land transportation means provided, and the space available at the site. Water depths will vary from about 10 feet for inland waterway vessels to 45 feet for ocean-going types. Wharf lengths may exceed 1,500 feet and provide space for several vessels. Widths of piers generally must increase with length and a width of 150 feet for a pier 1,000 feet long is nearly a practical minimum. The width of quays, since they abut the shore along their long side, is usually less critical.

Wharves, in common with most modern engineering structures, vary widely in design in order to best fit natural and other conditions prevailing at the site, to best utilize the materials available for construction, and to accomplish these things at somewhere near the minimum cost. Quays, which are less common than piers, are chosen where there is ample shore line space, an unusual condition in most modern ports. Piers, on the other hand, require ample width of waterway to permit maneuvering of vessels into berths. Seaports near the mouths of rivers are sometimes limited in the use of piers by lack of width in the rivers. In a few places in the world having rock

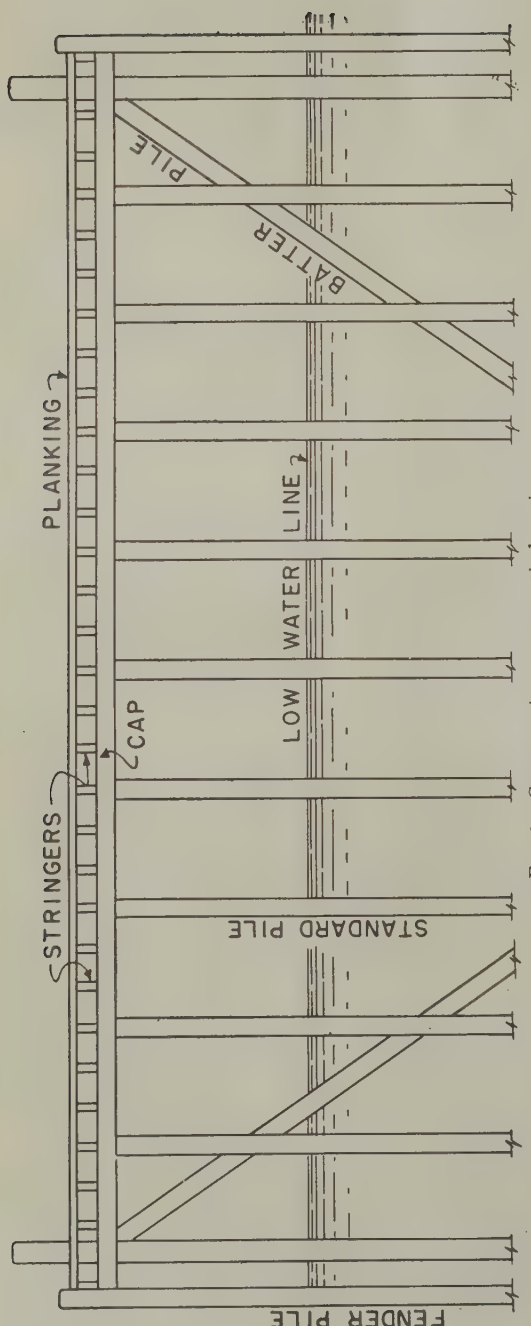


FIG. 1. Cross section, common timber pier.

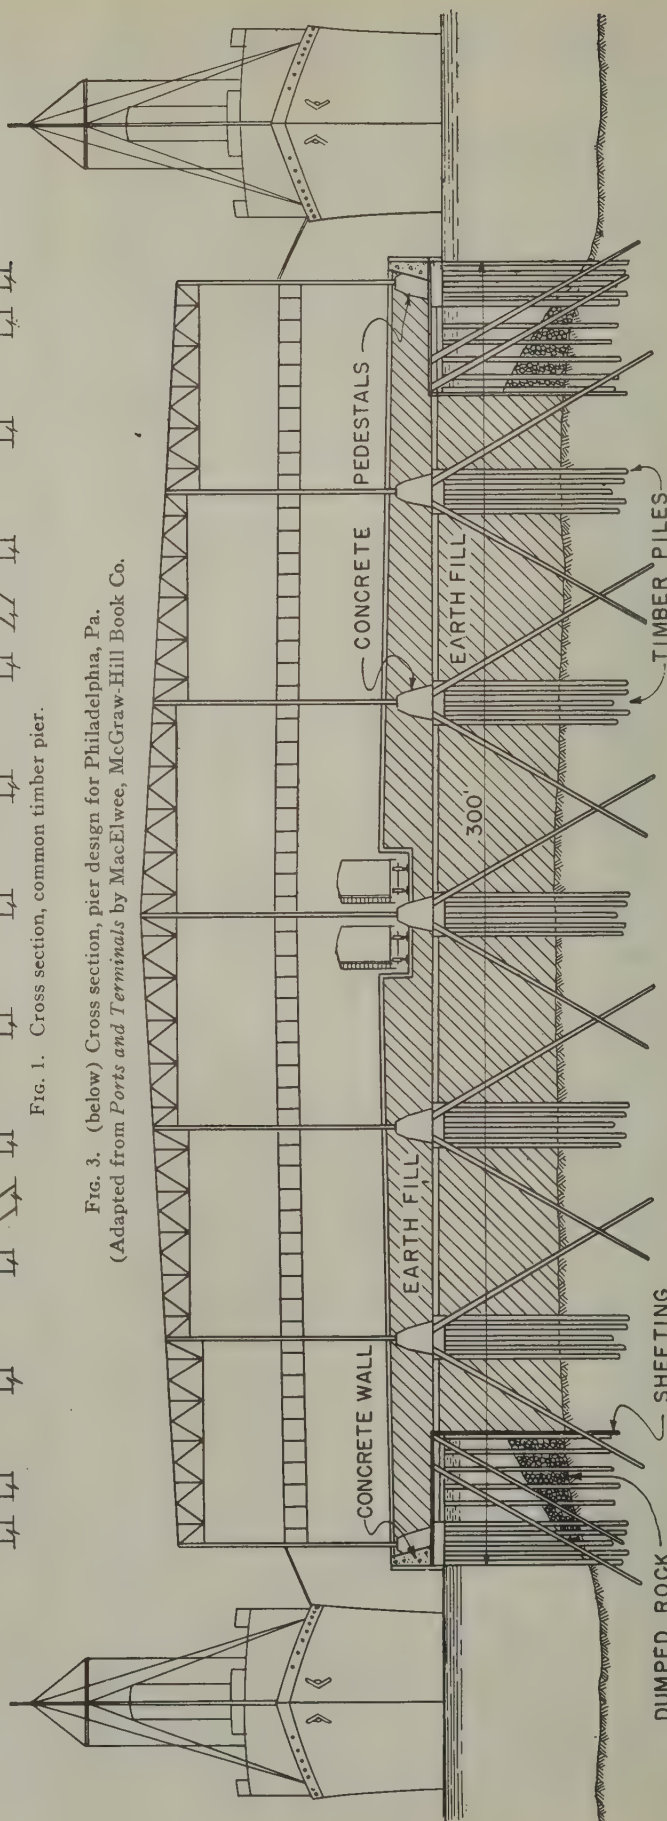

FIG. 3. (below) Cross section, pier design for Philadelphia, Pa.
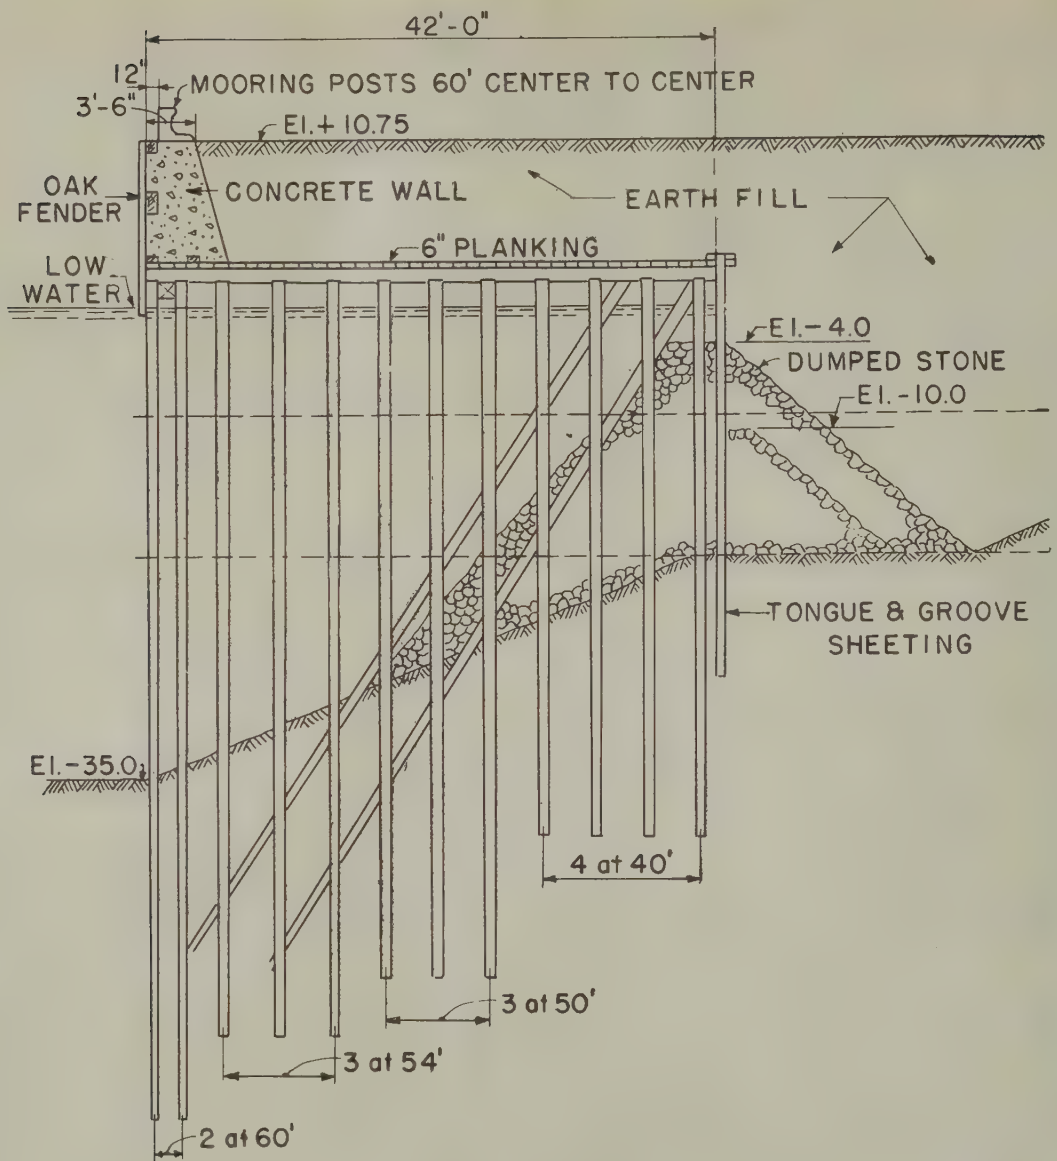
(Adapted from *Ports and Terminals* by MacElwee, McGraw-Hill Book Co.

shore lines, wharves have been created by excavating the rock to form vertical rock faces and horizontal rock floors. A much more common practice is to excavate the required depths in earth shore lines, and to form the vertical faces by means of walls of stone masonry, mass concrete, reinforced concrete, or pile bulkheads of wood or steel; and to form the horizontal surfaces by earth filling behind the walls topped by pavements of various materials. (Fig. 4.) Possibly the most common type of construction is a variation of this wherein, for reasons of economy, the vertical walls are dispensed with in whole or in part and mounds of stone or other available natural granular material are substituted therefor. The stone assumes a natural angle of repose of something less than 45° from the horizontal and, in order to provide the vertical aspect between the edge of the wharf deck and the full depth of the water, a pile structure is built over the rock slope which provides a floor or deck at the required height, and which adjoins the leveled earth back of the rock mounds. (Figs. 2 and 3.) These general descriptions apply to either quays or piers, the only difference being that a quay is a one-sided structure whereas a pier has two similar sides. In addition, many piers have been built taking little advantage of the natural site except the depth of water which is often augmented by dredging. (Fig. 1.) The entire structure is built up from the bottom usually on piles of timber, concrete, or steel, and sometimes on massive concrete structures carried down to firm foundation materials by any one of several subaqueous construction methods.

Design.—The design of wharves involves methods which are common to many civil engineering structures. Where walls are used, they are designed basically as ordinary retaining walls and, in the case of mass concrete walls, will often have base widths somewhere near one half the heights of the walls. Reinforced concrete walls of cellular or inverted T shape are likely to have bases somewhat wider than the above stated proportion. The exact proportions are, of course, dependent upon the nature of the foundation and backfill materials and upon the water levels both in front of the walls and within the backfill behind the walls. The latter material often is drained either by use of granular self-draining material, like sand and gravel, placed adjacent to the wall, or by the use of perforated drain pipes. One feature of many wharf wall designs which deserves especial attention is the tendency for the wall to slide on its base. This is important, due to the weak unconsolidated soil materials which form the foundation materials at many wharf sites. Soil mechanics offers a fairly precise solution to this design problem through the use of the so-called Swedish circle method of analysis. This analysis involves the selection of a critical circle of failure within the soil mass adjacent to the wall and passing close under the base of the wall or near the tips of the piles if they are used. By comparing the forces tending to produce rotation along the circular path by reason of the heavier soil weights and other loads on the landward side of the center of the circle with the restraining forces due to the sheer resistance of the soil along the periphery of the circle, a fair idea of the margin of safety of the wall against sliding may be obtained. A form of wall frequently used in wharf construction is known as the relieving type, a sketch of which is shown in Fig. 2. This type utilizes the natural stable slope of the backfill material to remove load from the back of the wall by the use of relieving platforms founded on piles, and is used for reasons of economy.

Piles are used in the foundations of the majority of wharf structures. Here again, the design of pile foundations is much the same as in other structures, except that at many wharf sites the foundation soils are deep and weak, thereby requiring very long piles. Timber piles were used almost universally in times past and are still commonly used. Douglas fir piles 120 feet long are obtainable on the west coast of the United States, but east coast species such as oak or pine are scarce in lengths over 60 feet. Steel and reinforced concrete piles, which are coming into increased use, can be used in lengths limited only by the practically available driving rigging. Steel piles up to 200 feet long have been used successfully. In computing design loads for piles, there are several pile-driving formulae available, such as the *Engineering News* formula, but experience has proved that full size pile-loading tests on the site of the work are worth their cost for a structure of any substantial size. In such tests, the piles are driven and loaded with steel rails, beams, earth filled boxes, or by jacks, and settlements are noted for various loads and driven lengths of pile. If the settlements are small, such as one quarter of an inch, under the load which the completed structure will place on the pile, the tested pile may be considered to indicate a length which will be satisfactory. The exact criteria, of course, depend upon the nature of the structure and its susceptibility to damage by foundation settlement. Loads commonly used for timber piles depending on soil friction to resist settlement are in the neighborhood of 15 tons per pile. If there is a firm stratum of soil such as dense sand or rock which can be reached by the piles, the loads per pile may be increased well above this figure because the piles will then have so-called end bearing which is more reliable than soil friction for support. This fact often justifies the use of very long piles, which in turn often dictates the use of steel or reinforced concrete piles rather than timber. It should be stated that many ship owners favor timber construction because of the resiliency obtained which produces less damage to vessels berthed alongside.

The layout or general arrangement, the overall dimensions and load carrying capacity of wharves are so dependent on site conditions, the size of vessels, and the nature of cargoes that it is difficult to state any general rules. There are several vessels in the North Atlantic trade in the neighborhood of 1,000 feet long and New York harbor has several piers 1,100 feet long to accommodate them. Since the pierhead line in New York and other United States harbors is established by the Corps of Engineers, Department of the Army, and since no pier can project beyond these lines, which allow 2,800 feet of unobstructed river at New York, those 1,100-foot long piers had to be excavated partly out of the rock of the shore. They therefore have concrete retaining walls founded upon rock for their shoreward portion and the more typical New York construction of a reinforced concrete deck on timber piles for their riverward ends. There are piers longer than this where ample space is available, but these are intended for berthing several vessels of the more usual length of 500 to 600 feet end to end along their sides. Furthermore,



(Courtesy of *Civil Engineering*)

FIG. 2. Cross section, quay at Bayonne, N. J.

in localities where adequate depths of water are far off shore, piers well over a mile in length have been built which provide for berthing vessels only at their extreme ends.

The New York piers mentioned above are 125 feet wide and this is quite a narrow width compared to other harbors such as Philadelphia and Baltimore where 300 feet of width is more common. One reason for the many narrow piers at New York is, of course, the value of the water frontage, although this is also high at other ports. A second reason at New York is the practice of railroad car lighterage service whereby railvessel transfers are made by ferrying railroad cars to the ship's side. Thus, there are no railroad tracks on many New York piers and less width is necessary. Slip space, that is the width of water between adjacent piers, is 400 feet at New York to provide room for lighters. Depth of water at the New York piers under discussion is 45 feet below low water. Depths at most ports for ocean-going ships are in the neighborhood of 30 to 35 feet.

Most wharves have sheds from 1 to 3 stories high. (Fig. 3.) These are necessary for temporary storage of cargoes while transferring from ship to truck or railroad, or vice versa. In some cases, inbound cargoes occupy one floor and outbound another. Frequently, passengers occupy a separate floor. In many instances, railroad tracks are provided along the edge of the pier for occasional loading of very heavy pieces of cargo and also at center lines of piers or landward edges of quays for the more usual shipments. Design floor loads occasionally are 1,000 pounds per square foot but more usually 500 to 600. Some wharves depend upon ships' tackle to move cargo between vessel and wharf, but many have cranes of a few tons' capacity to augment or assist the vessels' equipment. Unusually heavy loads frequently are moved by floating cranes which move from wharf to wharf. There are many wharves designed for highly specialized purposes with equipment capable of moving only one kind of cargo. Loaded railroad cars are transferred at some. Coal wharves accept loaded cars, turn them over, and chute the coal directly to the vessels. Wharves for iron ore loading and unloading are common on the Great Lakes and turnaround time of vessels is a matter of a few hours. Ce-

ment is loaded by blowing it through pipes and, of course, petroleum and other liquid products are piped. Belt conveyors are used for other products.

A design feature of many wharves is some sort of shock-absorbing mechanism along the wharf edge to minimize damage to the vessel and the wharf as the vessel is being brought to berth. The weight of vessels is so large that a very large amount of energy must be absorbed by the wharf or the vessel's plating, even if the vessel is brought to rest from an approach velocity of only one or two miles per hour. Timber wharves serve this purpose by their natural resiliency and a horizontal pier movement of nearly one foot is not uncommon nor too destructive. A reinforced concrete pier on the other hand could not accept such movements and buffers of one type or another are essential. In some instances, timber piles have been driven around the edge of concrete wharves for this purpose. In others, vertical timbers hinged at their lower ends and held out from the wharf by horizontal helical steel springs at their upper ends have been used. Hydraulic buffers have been used. Several types using heavy weights, usually of concrete, suspended in such a way that the horizontal thrust of the vessel will cause the weight to rise against gravity, have been successful. In most all cases, the striking surfaces are sheathed with timbers to minimize damage to the vessel's plating.

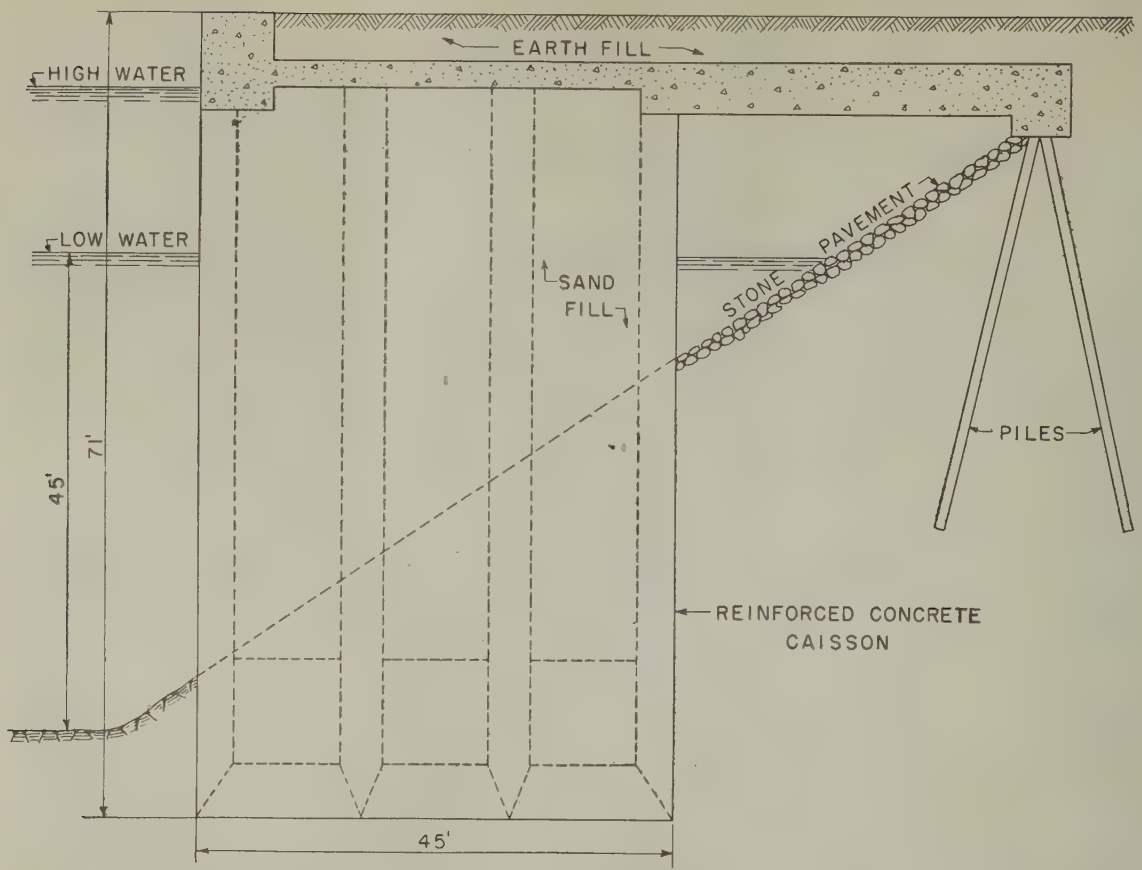
Waterfront structures, especially those on salt water, are subjected to some severely destructive influences. Marine borers attack timber structures in many parts of the world. In general, such destruction is most severe in the tropics, but certain of the pests have reached as far north as Halifax. *Teredo navalis* and *Limnoria terebrans* are the most widely distributed and the most destructive. The teredo, or ship worm, is worm-shaped up to 36 inches long and ¼ inch in diameter. Its head has a two-part calcareous shell for boring. It will bore into timber up to several feet above low water and hollow it out with non-connecting tunnels. Limnoria is a small crustacean about the size of a grain of wheat. It works within the timber between high and low water levels, and its borings are so close together that the timber is almost completely disintegrated. Creosote seems to be the best preservative against these pests. The timbers may be painted with creosote, or better still they may be impregnated with the material under pressure. Species of timber vary in their adaptability to the latter process and, of course, its use adds considerably to the cost. Nonetheless, little timber is used in wharf construction that has not been creosoted to some degree. It is important in handling creosoted timber that hooks or other tools, which gouge the surface, be not used, because such ruptures are apt to form entrance for marine borers.

Destruction by fire is a serious hazard for wharf structures. Creosoted timber burns readily, of course, and at waterfront locations, where oil spillage is common and high winds are frequent, the danger is increased. Many designs avoid the use of timber for this and other reasons, but some safeguards are effective. Some wharves have been sheathed around their perimeters to below low water, in order to prevent oil and other inflammable material from floating beneath the structure. Such sheathing must not be allowed to cut off the circulation of air, lest dry rot attack the enclosed timber. Fire walls of timber, metal, or masonry are usually installed in important structures to prevent the spread of fire, and sprinkler systems in the wharf sheds are a common feature. Decks of earth fill or concrete, or both, are often used on timber substructures to minimize the fire hazard.

The disintegration of concrete is accelerated by alternate wetting and drying, alternate freezing and thawing, the leaching action of salt water, and the erosive action of waves. All of these elements may exist at one wharf location and one or more is always present. The best defense against such disintegration is the use of well-designed, dense, and carefully placed concrete. In general, it may be said that if the water can be prevented from penetrating the concrete, the disintegration will be very slow. The concrete aggregate material should be durable in itself, with few soft particles and as little of it as possible subject to swelling when wet. The aggregate should have a particle shape as near cubical or spherical as possible, and should be well graded from the coarsest size (the largest possible which will fit easily between reinforcing rods or other elements of the structure), down to that portion of the material which will pass a number 100 sieve. The cement content should be higher for waterfront structures than for the average land structure, in order to better resist the aggressive action of the water. Air entraining cement appears to increase materially the impenetrability of the concrete. The water should be held to the minimum amount which will assure correct placement of the concrete with the aid of vibrators. Sufficient water to permit the concrete to flow should never be used. Correct amounts vary considerably, but there is seldom justification for more than seven sacks (7 cubic feet) of cement per cubic yard of concrete or more than six gallons of water per sack of cement. The precasting of concrete elements for wharves is often desirable because it is much easier to control concrete manufacture and placement conditions on land, and, furthermore, it minimizes expensive over-water work. The curing of concrete by keeping it constantly wet for seven days after placement is worthwhile from the point of view of durability.

Features of Recently Built Wharves.—The following brief descriptions cover wharves built since about 1935. Further details of these and others may be found by consulting the indexes of the magazine *Civil Engineering,* the magazine *Engineering News-Record,* or the *Transactions of the American Society of Civil Engineers* which are available in most public libraries.

Standard New York Pier Construction.—Most New York piers are founded on timber piles driven to 15 tons' bearing capacity. Such foundations are expected to last for 20 to 30 years and be good for another 20-year period by cutting off and replacing the piles above low water without disturbing the deck or superstructure. More durable construction has been considered wasteful due to the changing needs of shipping. The piles are driven on 10-foot centers each way and timber pile caps form bents transverse to the pier centerline. Decks are of reinforced concrete 10 inches thick and designed for loads of 500 pounds per square foot. Below deck, the pier is divided into 120- to 140-foot sections by transverse fire walls of concrete. Footings for the superstructure are carried to low water by means of concrete



(Courtesy of *Civil Engineering*)

FIG. 4. Deep-water quay well at Southampton, England.

pedestals on pile clusters. The superstructure is usually a 2-story building of four-column steel bents placed 20 feet apart. The second floor is designed for 300 to 400 pounds per square foot. The shed sides are turn-over doors along the pier length and the front shed (transverse at shore end) contains waiting rooms, offices, and boiler rooms. As stated heretofore, New York piers are relatively narrow at 125 feet wide and up to 1,100 feet long.

Quay at Bayonne, N. J.—At the site, the pierhead line is two miles from shore with only fringes of land above water. The project therefore required dredging to secure the desired 35 feet below low water and filling with dredge spoil to create land for the terminal and factory sites at an elevation 11 to 13 feet above mean low water. A wharf was constructed around the margin of the fill 9,300 feet long and 42 feet wide, as shown in Fig. 2. The wharf is of the relieving platform type designed for a dead load of fill of 750 pounds per square foot and a live load of the same amount, or 1,500 pounds total. The piles were driven to support 15 tons each and pile bents were spaced 5 feet on centers with 12 piles per bent most of which were 4 feet apart. Tongue and groove sheet piling was driven at the rear edge of the platform and a bank of riprap stone was placed on either side thereof. The dredged material was sand, gravel and silt and efforts were made to eliminate as much of the silt as possible near the quay. Wash borings indicated fine sand at elevation —20 and —30, with sand becoming coarser with depth, and test piles indicated adequate bearing power if driven to —50, that is, feet below mean low water. At one location, softer materials apparently existed to greater depths and two test piles 75 feet long were driven and test loaded. They penetrated 30 feet to elevation —60. One settled 0.74 inch and the other 1.14 inches under 30 tons, or twice the design load each. Upon load removal, the net settlement was 0.25 and 0.36 inch which was considered satisfactory. Based on these tests and pile driving experience on the job, a satisfactory pile resistance was established as follows: For penetration less than 30 feet, use the *Engineering News* formula. For 30 to 35 feet of penetration, require not less than 6 blows for the last foot driven. For 35 to 39 feet of penetration, not less than 4 blows for the last foot. For more than 39 feet, at least 3 blows. The hammer used was McKiernan-Terry 11-B-3.

Pier at Davenport, Calif.—A welded steel pier has been built which carries a railroad track, walkway, and two 12-inch pipelines for loading cement. The support is steel H beams driven to point bearing on shale. These steel piles are standard 8- to 10-inch rolled sections of 33 to 49 pounds per foot. The outside piles are driven through steel cylinders which are filled with concrete. The pierhead, at which the ships are berthed, is supported on four steel cylinders seven feet in diameter anchored by six H beams driven within each cylinder and concrete filled. All bracing is welded steel.

Pier at Halifax, Nova Scotia, Canada.—A pier of precast concrete cribs and fill 1,250 feet long and 300 feet wide has been built at Halifax. The cribs are reinforced concrete 42 feet by 52 feet, floated to the site, sunk by filling with siphons, and then filled with sand. The cribs

form the perimeter of the pier and the central portion is sand and rock fill.

Wharf at New Orleans, La.—The port of New Orleans, near the mouth of the Mississippi River, has the problem of unstable banks to contend with in the construction of its wharves, usually quays. The stream brings down heavy loads of silt when in flood and the banks are composed of this material which also extends to great depths below the river bed. Minor shifting of the river bed often starts the banks moving toward the river and sloughing to lower elevations, as deep-seated silt movements occur. Ordinary pile foundations have moved with these soil movements. In an effort to combat this condition, a quay 1,000 feet long by 75 feet wide has been built on large diameter steel caissons driven 90 feet through the silt and 10 feet into a stable sand horizon. The caissons, with a maximum design load of 320 tons, are from 33 to 54 inches in diameter and were driven with a 10,000-pound steam hammer with a 2,000-pound cast steel driving hood fitted to the top of the caisson. The caissons were built ashore and bulkheaded and floated to the site. Soil was removed from the caissons after driving, by use of water jets and compressed air, and concrete was placed within the water-filled caissons by tremies. Caissons were spaced 20 and 30 feet apart and were connected by welded steel rigid frames. Reinforced concrete was used for an 8-inch thick deck and the superstructure building.

Pier in New York Harbor.—A pier on the New Jersey side of New York harbor has a steel pile foundation of 14-inch standard rolled H sections 200 feet long. The pier is 600 feet long by 90 feet wide. Rows of 13 steel piles each are formed into bents with reinforced concrete pile caps 3 feet by 3 feet. A 10-inch thick reinforced concrete deck slab on reinforced concrete girders 3 feet 3 inches deep span 21 feet between pile caps. Crane supports are separated 9 inches from the deck slab all around to avoid whipping of the revolving cranes when ships strike the wharf. The outer half of the piles are jacketed with concrete 28 inches in diameter.

Wharf at Long Beach, Calif.—A wharf 32 feet wide by 2,500 feet long is supported on 1,000 concrete filled steel tubes 75 to 80 feet long. A steel sheet pile bulkhead is used on the filled side of the structure and is anchored into the fill with tie rods. Pile bents are 10 feet apart and piles in the bent 8 feet apart. This close spacing permitted reinforced concrete flat slab construction for the deck, which supports 2 to 4 feet of earth fill and 750 pounds per square foot live load. Design loading is as high as 58 tons per pile and a 140-ton test load caused settlements of 1.75 inches which reduced to one inch upon unloading. Heavy rubber tubing 14 inches long and 7 inches in diameter between the wharf edge and a continuous heavy timber forms a bumper for ships striking the wharf. Sheds are 200 feet wide of clear spans.

Quay Wall at Southampton Eng.—Fig. 4 is a cross section of a quay wall at Southampton, England. The wall is formed of concrete caissons 45 feet by 45 feet, sunk by dredging sand from the interior cells. The landward cells subsequently are filled with sand. To reduce pressures on the rear of the wall, a rock paved slope is used as well as a concrete relieving platform. While types of structures vary in Europe, as they do in America, it may be said that more massive construction generally is used in Europe, as is typified by this quay wall.

Ralph L. Bloor,
Office of the Chief of Engineers, Department of the Army.

WHAT EVERY WOMAN KNOWS, play by James M. Barrie, Scottish novelist and dramatist, produced in 1908, published in 1918. Maggie Wylie is a plain, small, modest but resolute spinster of 26, with no prospects of marriage, when John Shand, an ambitious, impecunious student five years younger, breaks into the Wylie library in a bizarre effort to advance his learning. Maggie's father and two brothers at once seize this as a heaven-sent opportunity to provide a husband for her in exchange for financing John's education. All are portrayed as Scottish to the marrow.

John, though lacking in a sense of humor, does amazingly well; in six years he is elected to Parliament. He goes through with the agreed marriage, though frankly admitting he does not love Maggie. On her part her one desire, carried out with passionate devotion and self-effacement, is to help him realize his political ambitions; she types his speeches for him.

At this point enters Lady Sybil Tenterden, worldly, charming, beautiful—all that Maggie is not; John quickly loses his head over her. Maggie, facing her problem with determination, is ready to give John up if he should find greater help and inspiration in her rival. After a brief period in the company of Sybil it becomes apparent that the novel ideas and shafts of wit that had propelled John to the top were missing from his new speeches. It is hard for him to understand why; for, as is the way with men, he has believed in his strength and gloried in the conviction that he has risen all by himself. But, says Maggie, the wife of every successful man knows better, and only smiles.

WHAT PRICE GLORY?, a war comedy by Maxwell Anderson and Laurence Stallings, was produced in New York in 1924 under the direction of Arthur Hopkins. It is usually ranked with R. C. Sheriff's *Journey's End* as the best dramatization of the ordeal of trench fighting in World War I.

The play owed its success to vivid creation of character and atmosphere rather than to plot. The characters are United States Marines—old-time professional soldiers mingled with green recruits. The thread of formal plot is the long-standing rivalry between two of the old-timers, Captain Flagg and Sergeant Quirt, who have come up together in the service. As the play opens, Quirt has just been reassigned to Flagg's company as top sergeant; the company is in rest camp in a French village, and Flagg is going off on leave. In his absence, Quirt supplants him as lover of Charmaine, the daughter of the local innkeeper. On Flagg's return, the girl's father complains that she has been seduced. Flagg orders Quirt to marry her, but before the ceremony can be performed the company is ordered to the front.

Act II is staged in a frontline dugout. On accomplishing its mission, the remnant of the company is relieved, but in Act III, before the weary men have had a chance to rest, all leaves are cancelled and the company is ordered back to the trenches. The curtain falls as the wounded

Quirt hobbles after the others, calling, "What a lot of . . . fools it takes to make a war!"

When originally produced, the play created a sensation because of the relatively uncensored profanity put in the mouths of the soldiers. Flagg and Quirt are tough, hard-drinking, unromantic, but they know how to take care of their men, and to lead them. For such professionals, war is neither a noble crusade for an ideal nor a dashing quest of glory. It is a messy job which they are paid and trained to carry through as best they can.

WHATCOM, Washington, former county seat of Whatcom County. See BELLINGHAM.

WHATELY, hwāt'lĭ, **Richard,** English prelate, archbishop of Dublin: b. London, England, Feb. 1, 1787; d. Dublin, Ireland, Oct. 8, 1863. He was educated at Oriel College, Oxford, and in 1819 made his first appearance as an author by publishing his since famous *Historic Doubts Relative to Napoleon Bonaparte.* This pamphlet was among the most popular of the author's writings, more than 12 editions of it having been published. Its purpose was to show that objections of the same kind as those brought forward by skeptical writers of the truth of the Gospel narratives, founded on what seem to be certain inconsistencies in these narratives, may be brought against any well-known and incontrovertible piece of history, such as that of Napoleon Bonaparte. In 1822 he delivered a series of lectures on party feeling in matters of religion. In the same year he received the living of Halesworth in Suffolk, and was appointed principal of St. Alban's Hall, Oxford, in 1825. In 1826 was published perhaps the most widely known of his works, *The Elements of Logic,* and the scarcely less popular *Elements of Rhetoric* in 1828. Whately was appointed professor of political economy in 1830. The lectures he then delivered were afterward published under the title of *Introductory Lectures on Political Economy.* In Oxford, Whately stood in the front rank of those who held liberal views in ecclesiastical and social matters and among these his earnest love of truth, his contempt for arguments resting solely on tradition and the keenness of his logic gave him great influence. In 1831 he was appointed archbishop of Dublin and bishop of Glendalough. He warmly embraced the cause of common unsectarian religious education for Protestant and Roman Catholic schools and wrote manuals suited to this purpose.

WHEAT, hwēt, a grass of the Gramineae family, of the tribe Hordeae, and of the genus *Triticum,* is the most widely grown of all the cereal grains. Except in the rice-eating regions of Asia, wheat products are the principal cereal foods of an overwhelming majority of the world's inhabitants. In the United States, food products from wheat contribute about one fourth of the total food energy requirements of man; and in European countries, particularly France and Italy, they make up a considerably greater proportion of the diet.

The pre-eminence of wheat as a food is due to several factors. It is adapted to a wide variety of soil and climatic conditions and can be grown extensively throughout the world. It is economical to produce and gives good yields of grain with excellent storage properties. Its great popularity as a human food is due to its mild, acceptable flavor, and the unique ability of its principal proteins to form gluten when mixed with water to make a dough. The gluten gives a soft springy quality to bread doughs and enables them to retain the carbon dioxide which is produced by yeast fermentation; this permits the production of light, finely textured loaves of bread. Flours from other cereals such as barley, corn, rice, and rye, which do not have gluten-forming properties, yield rather heavy loaves.

History.—Wheat played an important part in the development of civilization and was grown before the dawn of recorded history, so that its origin is obscure. The most ancient languages mention wheat, or corn, and archaeologists have found carbonized grains of wheat in the prehistoric lake dwellings in Switzerland, in remains from the Stone Age in England, in the tombs of the pharaohs in Egypt, and in the excavations of ruins in Turkey, some of which date back to 4000 B.C. There is evidence that wheat was cultivated in China in 3000 B.C. Some scientists believe that wheat originated in Mesopotamia (Iraq) although many others hold the view that the plant once grew wild in the valleys of the Euphrates and Tigris rivers and spread from these regions to the rest of the world.

Wheat is not believed to have been cultivated in America prior to its discovery by Christopher Columbus, who brought it to the West Indies in 1493. It was taken to Mexico by Hernándo Cortés in 1519, and Jesuit and Franciscan missionaries carried it into what is now Arizona and California. Production was started in Massachusetts and Virginia by the colonists early in the 17th century. It was not as well adapted to the coastal area as corn; but as settlers moved into the Ohio Valley and the West, wheat became one of their main crops.

World Production.—Wheat has a range of cultivation which is probably greater than that of any other crop, and is being seeded and harvested somewhere in the world each month of the year.

The following table gives world production and acreage figures for a period of 20 years.

[1] Years shown refer to years of harvest in the Northern Hemisphere. Harvests of Northern Hemisphere countries are combined with those of the Southern Hemisphere which immediately follow; thus, the crop harvested in the Northern Hemisphere in 1955 is combined with preliminary forecasts for the Southern Hemisphere harvests which begin late in 1955 and end early in 1956. [2] Figures refer to harvested areas as far as possible. [3] Revised estimates for Northern Hemisphere countries, for Southern Hemisphere, preliminary forecasts based largely on acreage and weather conditions to date. [4] Estimated totals which in the case of production are rounded to millions, include allowances for any missing data for countries shown and for other producing countries not shown. [5] Figure for 1935 only. [6] Comprises Albania, Bulgaria, Czechoslovakia, Eastern Germany, Hungary, Poland and Rumania. [7] Average of less than 5 years. [8] Estimates for Syria and Lebanon not shown separately during this period. [9] Figures for the period shown are not strictly comparable since figures for 1953–1955 include allowances for non-reporting areas, which were not included in earlier figures shown, but were included in estimated total for Asia. [10] Production on European holdings only.

Foreign Agricultural Service. Prepared or estimatedon the basis of official statistics of foreign governments, reports of United States Foreign Service officers, results of office research, or other information. Prewar estimates for countries having changed boundaries have been adjusted to conform to present boundaries.

Wheat is grown at elevations of 8,000 to 10,000 feet in the tropics of Mexico, northwestern South America, and Abyssinia, and below sea level in the Imperial Valley of California. It grows within the Arctic Circle in Europe, Asia, and North America, and in such warm countries as Brazil and the tropics of the Philippines. In the world as a whole, several thousand varieties are grown. The cultivation of wheat on a large scale is confined principally to temperate regions where the annual rainfall is from 15 to 35 inches; it does not do well on sandy and peat soils, and is best adapted to loam and clay soils which are well supplied with organic matter (humus).

In Europe there are three principal wheat growing regions: (1) the plains of southern Russia and the Danube basin (including Rumania and Hungary); (2) the countries bordering the Mediterranean Sea, especially Italy; and (3) northwestern Europe (Germany, France, Holland, Belgium, Great Britain). In North America wheat is grown principally in the Great Plains area of the United States and Canada and in the Columbia River basin (eastern Washington and Oregon).

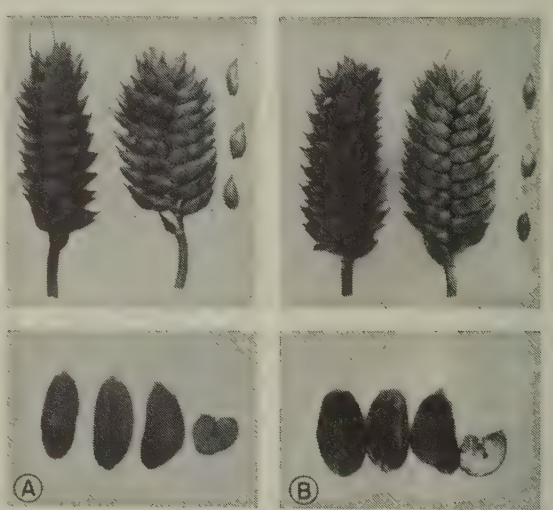
Other leading wheat producing areas are located in the central part of Argentina, southern Australia, and Pakistan. The inequality in wheat production and consumption results in a large international trade in wheat. Under normal world conditions, vast streams of wheat pass from the surplus producing countries of North America, Argentina, and Australia to the countries of deficit wheat production, principally in western Europe.

United States Production.—Three botanical species of wheat, *Triticum vulgare* (common wheat), *Triticum durum* (amber and red durum wheats), and *Triticum compactum* (white and red club wheat), each representing several varieties, are grown in the United States, but members of the *T. vulgare* group represent nearly 95 per cent of the total production. The common wheats differ in such physiological characteristics as spring or winter habit of growth, earliness, yield, resistance to drought, cold, plant diseases, and in such morphological characteristics as the presence or absence of awns, color (red and white), and kernel texture (hard and soft), as well as in milling and baking behavior.

For commercial purposes, the common wheats are classified in four major groups: hard red spring, hard red winter, soft red winter, white wheats (winter and spring). Spring wheat is sown in the spring and is harvested in the late summer. Winter wheat is planted in the fall in regions where the winters are only moderately severe; it develops a root system before the onset of cold weather and becomes dormant during winter. In the spring, the plants make a vigorous growth and the wheat is harvested in the early summer. In areas where it can be grown, winter wheat will usually give greater yields than spring wheats.

The latest survey by the United States Department of Agriculture of the acreages devoted to production of the different classes of wheat was conducted in 1949 and showed that hard red winter wheat represented 54.2 per cent of the total acreage; hard red spring wheat, 20.8 per cent; soft red winter wheat, 13.0 per cent; white wheat (including white club), 7.8 per cent; and durum (amber and red), 4.2 per cent. In that year 75,910,000 acres of wheat were harvested with an average yield per acre of 14.5 bushels to give a total production of 1,098,415,000 bushels; of this quantity 148,516,000 bushels were used for seed, feed for livestock, and other uses on the farms where it was grown, and 949,899,000 bushels were sold.

Hard red winter wheat is grown principally in the southern and central portions of the Great Plains, the greatest acreages occurring in Kansas, Nebraska, Oklahoma, Texas, and Colorado. Hard red spring wheat is grown in the northern portion of the Great Plains area, in the states of Minnesota, North Dakota, South Dakota, and Montana, where the winters are severe and semi-arid conditions prevail. Soft red winter wheat is grown east of the Great Plains area and south of Wisconsin, in regions which are usually characterized by ample rainfall and moderately cold winters. It is the leading class of wheat in Ohio, Indiana, Illinois, Missouri, Pennsylvania, Maryland, Virginia, West Virginia, New Jersey, Delaware, North Carolina, South Carolina, Georgia, Kentucky, Tennessee, and Alabama. White wheats are grown chiefly in the Pacific



(A), Elgin and (B), Hybrid 128 wheats.

Coast states and in New York and Michigan; the leading producing states are Washington, California, Idaho, and Michigan.

Durum wheat was introduced into the United States from Russia by Mark A. Carleton, cerealist of the United States Department of Agriculture, during the latter part of the 19th century for cultivation in the north central region of North Dakota where the existing spring wheat varieties gave relatively poor yields because of arid conditions and their relatively greater susceptibility to the prevailing physiologic strains of wheat stem rust. In recent years about 80 per cent of the entire durum crop has been grown in North Dakota, 15 per cent in South Dakota, and the remainder in Minnesota.

Cultivation in the United States.—Wheat is grown on about one third of the farms of the United States, and in some areas it is almost the sole source of farm income. In the major producing regions of the Great Plains and the Pacific Northwest where there is limited rainfall, wheat is often grown on the same land year after year; or the land is allowed to remain idle, with occasional cultivation every second or third

year to conserve moisture and nitrates for the following crop. In the eastern United States wheat is nearly always grown in rotation with other crops; when it follows corn or soybeans, the land is usually prepared by disking. The application of fertilizers is seldom profitable in the major wheat growing areas of the West, but in the Central and Eastern states mixtures containing phosphorus and potassium compounds are commonly applied at seeding time. Nitrogen is usually supplied through the use of legume crops in the rotation, although a late winter or early spring application of nitrogenous fertilizers is beneficial in the South and in wet seasons in the East.

In states where wheat is extensively grown, it is usually harvested and threshed in one operation by a machine called a combine. It is necessary to delay harvesting from 7 to 14 days after the normal time for cutting with a binder in order that the moisture content will be reduced to 14 per cent or less so that the threshed grain can be stored safely. The culture of wheat in the United States has been so completely mechanized that only about three man-hours of labor are now required per acre (20-bushel yield) as compared with 58 man-hours 100 years ago.

(A), Kubanka and (B), Mindum wheats.

Wheat Varieties.—Wheat production involves many hazards, such as drought, winter killing, plant diseases, and attacks by insects (see WHEAT, DISEASES OF; WHEAT PESTS), but yields have been greatly stabilized during the past few decades through the development of new varieties by the United States Department of Agriculture and state agricultural experiment stations. In a program of this nature, one must breed for resistance to various diseases, and these characteristics must be combined with high yield, proper maturity, strength of straw, and satisfactory milling and baking quality. This is accomplished by crossing two or more varieties having the individual characteristics which are wanted, and selecting descendants that combine the good properties of the parents. A period of 12 to 15 years are required to produce a new variety, and a continuous breeding program must be carried out, since the prevalence of certain plant diseases and insects is continually changing and new physiologic strains of fungi appear to which present resistant varieties may be susceptible.

Wheat varieties. (A), Awn types: *1*, Supreme; *2*, Onas; *3*, Thatcher; *4*, Ceres. (B), Spike shapes: *1* and *2*, fusiform; *3* and *4*, oblong; *5* and *6*, clavate; *7*, elliptical.

The history of Thatcher, a hard red spring wheat variety distributed in 1934 and resistant to stem rust, serves to exemplify the problem faced by wheat breeders. For several years this variety was grown more extensively than any other spring wheat in the United States and Canada because of its wide adaptability, resistance to stem rust, and good milling and baking qualities. When stem rust was controlled, losses from leaf rust (which is caused by a different organism) became more prevalent and several new varieties of wheat were released (Newthatch, Rival, Henry, Mida, and others). They were resistant to both leaf and stem rust for a

few years and replaced Thatcher wherever leaf rust was a problem. All commercially grown spring wheats became susceptible to leaf rust in 1944 due to an increase in the prevalence of a new race; during the summer of 1950, all varieties were attacked by a race of stem rust later identified as 15 B (first discovered in 1939). A serious stem rust epidemic occurred in 1953, and the spring wheat breeding program has been vigorously prosecuted to develop satisfactory varieties which are resistant to this strain.

Approximately 200 varieties of wheat are grown on farms throughout the United States.

Commercial Classification of Wheat.—The United States Grain Standards Act, which was passed in 1916, provided for the establishment of official standards for the common grains and the federal licensing and supervision of grain inspectors. These standards have been revised

(A), Thatcher and (B), Marquis wheats.

from time to time, and are designed to sort each grain into a number of categories according to quality. Wheat is divided into seven classes on the basis of botanical species, habit of growth, and color: hard red spring, durum, red durum, hard red winter, soft red winter, white wheat, and mixed wheat. Five of these are divided into subclasses on the basis of such factors as kernel density, geographical origin, or the presence of certain varieties. Each subclass is separated into a number of grades on the basis of plumpness, soundness, cleanliness, extent of weathering, and the presence of insects, smut, garlic, and the like. The standards also specify maximum moisture limits for all the regular grades (14.5 per cent for hard red spring, durum, and mixed wheat, and 14.0 per cent for the other classes). The hard wheats (which include hard red spring, hard red winter, and hard white wheats) are valued for the production of flours used in making yeast-leavened bread. Soft red winter, soft white, and white club wheats are best suited for making chemically leavened baked products such as biscuits, cakes, and pastries. Amber durum wheat is prized for the manufacture of such alimentary pastes as macaroni, spaghetti, and noodles. Red durum wheat is unsuitable for milling purposes and is used principally as a poultry and livestock feed. The suitability of wheat for these various purposes depends primarily on its protein content which is reflected in a general way by the hardness and translucency of the kernels; usually the hard, translucent types are considerably higher in protein content than soft wheats with a starchy, opaque appearance.

Chemical Composition.—Wheat consists principally of proteins and starch with smaller quantities of other carbohydrates, fats, pigments, certain vitamins, and minerals. It contains the important B-vitamins—thiamin, riboflavin and niacin—but no vitamin C unless the grain is sprouted. The yellow pigments present in wheat consist chiefly of xanthophyll, which does not give rise to vitamin A when ingested. The embryo (germ) of wheat is a rich source of vitamin E.

The protein content of wheat is influenced principally by the soil and climatic conditions under which it is grown. Considering the United States as a whole, the protein content varies from 7 to 19 per cent. In general, regions with a mild, humid climate, which is typical of land areas near large bodies of water, result in a long growing and ripening period and produce starchy kernels of low protein content. In contrast, the Great Plains area is characterized by relatively hot dry weather during the ripening of the grain and yields wheat with a high protein content. Within a climatic zone, seasons of high rainfall or the use of irrigation, especially during the ripening period, results in a decrease in protein content with an increase in yield.

The moisture-retaining properties of soil have more influence on the protein content of wheat than the level of fertility; nitrogenous fertilizers frequently enhance the yield quite markedly without greatly affecting protein content. In general, however, the protein content of wheat is raised by increasing the available nitrogen in the soil; thus, wheat grown on summer fallow or after legumes is usually of higher protein content than when grown after cereal grains or grasses. Although soil and climatic conditions have the greatest influence on protein content, genetic factors are involved since some varieties produce wheat of higher protein content than others when grown in the same environment. (For the structure of the wheat kernel, see FLOUR AND FLOUR MILLING.)

Professor of Agricultural Biochemistry, University of Minnesota.

WHEAT, Diseases of.—Diseases of wheat are caused chiefly by fungi, bacteria, nematodes, and viruses. They cause enormous losses and are among the greatest of obstacles to efficient and stable production of wheat. Many of them are insidious and widely prevalent every year, others are destructive locally, while still others are widespread and become epidemic only in certain years. The amount of damage they cause varies greatly from season to season, and for most diseases also from one field to another. In some areas epidemics of diseases such as leaf and stem rusts, smuts, scab, and root rot cause losses of 25 to 50 per cent or more of the potential crop; sometimes there may be enormous losses over wide areas.

In 1916 one of the most disastrous epidemics of stem rust on record swept over the spring wheat growing areas in the United States and Canada and destroyed approximately 280 million bushels of wheat. In 1935 and 1937 there were destructive epidemics of stem rust which virtually ruined the wheat crop in the upper Mississippi Valley. Again in 1953 a widespread and extremely destructive stem rust epidemic almost annihilated durum wheats in Minnesota and the Dakotas; the estimated loss for all durum wheats was 65 per cent of the potential crop. In most countries rusts are definitely a limiting factor in wheat improvement and production. Because of frequent epidemics of certain diseases and the vast areas involved, it is difficult to estimate accurately the average annual percentage of loss caused by diseases of wheat. In many parts of the world it usually amounts to 10 to 15 per cent or more of the potential crop.

The more important diseases of wheat are: stem rust caused by *Puccinia graminis tritici;* leaf rust caused by *Puccinia rubigo-vera tritici;* bunt caused by *Tilletia foetida* and *T. caries;* scab or Fusarial head blight caused by many species of *Fusarium,* particularly *F. graminearum;* and seedling blight and root rot also caused by many species of fungi, especially of the genera *Fusarium, Helminthosporium, Pythium,* and by *Ophiobolus graminis.* In addition there are many other diseases of less importance. These may be of considerable economic consequence in some areas every year and in some years they may cause severe damage, particularly when susceptible varieties are grown.

Bunt or stinking smut since historical times has been one of the major diseases of wheat. Bunt decreases yield, creates difficulties in threshing and processing, and lowers the quality of the grain. It is worldwide in distribution, although it is usually more prevalent in the drier regions of the world. In the United States, bunt is particularly destructive in the Pacific northwest. In contrast, loose smut, *Ustilago tritici,* is prevalent only in regions where there is high relative humidity during the blooming period in wheat—a situation which is usually encountered in the soft winter wheat regions of the United States.

Stinking smut usually modifies the spike so that each kernel or seed is replaced by a smut ball that contains 5 to 10 million blackish spores (called chlamydospores). A fishlike odor, caused by trimethylamine, is characteristic, hence the name stinking smut. Smutty wheat commands a lower price on the market because spores adhere to threshed grain and must be washed off before milling.

Fusarium head blight (scab) damages wheat severely, especially in the corn belt where temperature and relative humidity are high during the blossoming period. The growth of the fungus (species *Fusarium*) in the developing kernel results in the production of substances toxic to man and certain animals. Violent nausea and stomach soreness result from eating scabbed grain. In Russia where infected grain was once used extensively for making bread, the product was known as intoxicating bread. At present scabby kernels are removed effectively from seed lots by cleaning equipment; hence scabby kernels do not occur in large quantities in milled wheat products. Certain animals, especially pigs, strongly dislike scabby grain and fail to make normal gains in body weight when fed scabby wheat and barley.

Root rots of wheat are caused by many microorganisms and are among the more important diseases of wheat. They are debilitating, insidious, and usually inconspicuous. The destructiveness varies greatly with the season, the locality, and the variety of wheat grown. The pathogens live on or in the seed, soil, and dead plants. They invade all underground parts of the plant and induce seedling blight, root decay, and premature death of older plants. They tend to multiply in the soil when wheat or other susceptible crops are grown year after year.

Since the soil is actually teeming with microscopic life—protozoa, bacteria, and fungi—there is actually a biological warfare among them. Because of such intense competition among soil organisms many of the pathogens are destroyed, including those that cause bunt, scab, foliage blight, and root rot; hence many diseases fail to develop. In fact, if it were not for this constant natural biological warfare in the soil, it would be virtually impossible to grow wheat continuously on our vast prairies and plains.

Sources of Infection.—Wheat kernels frequently are invaded and discolored by fungi and bacteria. Such seeds often are the source of primary infection for root-rotting pathogens, especially species of *Fusarium* and *Helminthosporium.* Moreover, badly discolored seeds—a condition known as black point—are undesirable in making semolina. In addition, storage molds, usually *Aspergillus* and *Penicillium* species, often invade the kernels after harvest and cause "sick wheat," making such wheat undesirable for milling and baking. If the wheat is stored at moisture contents above 13 per cent, molds grow into the germ of the grain and gradually weaken and finally kill it. In most seed lots the infection by storage molds is invisible and can be detected only by special techniques.

The microorganisms that cause rusts, smuts, mildew, root rot, foliage blight, and other diseases of wheat are living, moldlike parasitic plants. They grow, hybridize, and produce spores ("seeds") by which they multiply and spread. Under environmental conditions favorable to their growth, the spores germinate and penetrate the wheat plant where they establish parasitic relationships. Bacteria and viruses also cause destructive diseases of wheat.

Pathogens such as fungi and bacteria are readily carried on or in the seed, by insects, and by wind. The wind is the most effective agent of dissemination of many fungi. Spores of rust and other pathogens have been caught more than three miles above the ground and there is good

circumstantial evidence that they are carried hundreds of miles by strong winds. As insects and wind have no respect for national boundaries, many diseases are of international scope and importance. One striking example is stem rust of wheat in North America, for wheat is grown from south-central Mexico to the plains of Canada, a distance of 2,500 miles. This vast area devoted to wheat is unbroken by natural barriers. Billions of rust spores are carried northward every summer by the prevailing winds from Mexico and the southern United States to wheat areas in the northern United States and Canada where the rust spores frequently initiate destructive epidemics.

Sometimes stem and leaf rust spores settle down at the rate of one million or more per square foot in a 24-hour period. An acre of wheat with 10 per cent rust infection would produce 20 pounds of rust spores and there are about 180 billion spores (uredospores) in a pound. In epidemic years there are vast areas of wheat with 65 to 95 per cent of rust infection, and the enormous number of spores produced on 20 to 30 million acres of wheat is almost incredible. In the fall the rust spores are usually blown from Canada and northern United States southward where they initiate new infection on winter wheat. Obviously, the control of rust is an international problem. So is the control of many other plant diseases.

Parasitic Races of Fungi.—Not only are diseases of wheat caused by many distinct species of fungi but most of the species comprise many parasitic races. Thus, within the species of *Helminthosporium sativum* there are hundreds of distinct cultural races that can be identified as such when grown on artificial media. Many of these races differ greatly in their parasitic capabilities on wheat and other cereals. Perhaps *Puccinia graminis tritici* (stem rust) is a better example of physiologic specialization. In the variety *tritici* of stem rust, more than 250 distinct parasitic races are delimited and there are perhaps many more in existence.

Rusts are obligate parasites, and spores from races of the same species are similar under the microscope. Hence, races of a rust can only be distinguished and identified by their parasitic effect on certain varieties of wheat, called rust differentials. Each such wheat variety may be resistant to some races, moderately resistant to others, and completely susceptible to still others. Extensive rust surveys over much of the world indicate that the prevalence of races may vary from one place to another and from one year to another. Thus, a variety of wheat may be resistant in one area or country but completely susceptible in another, and vice versa, because of the existence of different races of the pathogen and the precedence or predominance of different races in different countries at a specified time.

Changing Disease Problems.—Disease problems in wheat are continually changing, chiefly because new pathogens evolve, or are introduced from other regions. Sometimes problems change because minor diseases become major diseases. The probability of establishing a foreign pathogen or new virulent race of a native pathogen is even greater now than it was in the past because of the mass movement of many materials and men during and following World War II. Also, changes in cropping systems and the planting of new varieties may shift disease problems of wheat.

The introduction of a new variety of wheat frequently brings about tremendous shifts in the prevalence of diseases hitherto considered unimportant in a particular region. When Marquis wheat replaced Preston, Haynes bluestem, and Glyndon fife in spring wheat regions from 1910 on, scab, hitherto a minor disease, became a major one, whereas the bunt problem decreased greatly. Then, with the introduction of the two stem rust resistant varieties, Kota and Ceres, about 1925, leaf rust, bunt, and loose smut became major diseases simply because these varieties were especially susceptible to certain races of the fungi that cause these diseases and that were present where the new varieties were grown. The release of many other varieties during a 20-year period (1930–1950) has repeatedly shifted the relative importance of diseases. Population shifts in the prevalence of parasitic races frequently are responsible for severe rust attacks on varieties that are resistant to the previously prevalent rust races.

Extensive surveys have shown that the prevalence and distribution of physiologic races of rust may change gradually over a period of many years or they may change rapidly in a single year. Stem rust race 56 was first found near rusted barberries in the north-central United States in 1923, but it did not become widely prevalent until 1935 when it virtually eliminated the growing of the wheat variety Ceres. Race 15 B, found occasionally near barberry bushes in the eastern United States prior to 1950, became the dominant race in the United States and Canada in that year, and in the following year it became prevalent also in Mexico. This race attacks all of the commercial, hitherto resistant varieties of wheat, and it was responsible for the destructive epidemic in the hard red spring and durum wheat areas in the United States and Canada in 1950 and 1953.

Past history has shown that new races of the bunt fungus developed following the release of a new bunt-resistant variety of wheat in the Pacific northwest. The population of the new races of bunt is greatest in regions where the new smut-resistant varieties are grown. If a new race of a pathogen can attack a so-called resistant variety, then the chances are good that the more extensively this variety is grown, the more rapidly will the new race multiply. Thus, a new variety may appear to lose its resistance, but in most cases it can be demonstrated that loss of resistance is due to the increase of new parasitic races of the pathogen.

Hybridization of Plant Pathogens.—Plant pathogens are not static; they hybridize and mutate just as higher plants do. Many new and virulent races of smuts and rusts have been produced by hybridization between existing races or biotypes. Fertile interspecific hybrids have been obtained by hybridization between two species of smut, *Tilletia caries* and *T. foetida*.

Hybridization frequently results in marked changes in pathogenicity, and new races often are produced that are more virulent than the parents. New races may attack hitherto resistant varieties of wheat that have recently been released to growers. The practical importance of hybridization in nature is most clearly apparent in stem rust.

Races of stem rust can hybridize readily on

common barberry, and apparently this occurs frequently in nature. As many as 18 races have been derived from a single cross between biotypes of a single race. Extensive studies made cooperatively by the United States Department of Agriculture and the University of Minnesota have shown that different kinds of races and biotypes are 10 to 20 times more numerous near barberries than away from them.

The sexual stage of stem rust occurs only on barberry and this has been one of the major reasons for the eradication of rust-susceptible barberries in at least 18 states. The role of barberries, however, in the production of initial inoculum resulting in primary infection centers was of tremendous importance before these bushes were eradicated from spring wheat areas. Although more than 448 million barberry bushes have been destroyed, some still remain and the campaign to eliminate them continues.

Treatment and Control.—Although many diseases of wheat such as root rots, scab, and bunt, cannot be completely prevented, particularly where wheat is grown extensively and intensively, they can be materially reduced by good agricultural practices. Sound seed of recommended varieties should be treated with a fungicide to eliminate the pathogens from the seed and to protect the seed and seedlings against seed- and soil-borne organisms, such as species of *Fusarium, Helminthosporium, Pythium,* and *Tilletia.* The seed should be sown only deep enough to provide adequate moisture for germination. Also, a good cropping sequence should be followed. The seed beds should be well prepared, and fertilizers should be applied if there is a deficiency of essential elements. As varieties differ greatly in susceptibility, only the varieties recommended for particular regions should be grown.

Despite many difficulties in controlling plant diseases, much progress has been made in the development of disease-resistant varieties of wheat. Although varieties may be only temporarily resistant, they have greatly reduced the danger of destructive epidemics and lowered the cost of production. Since most pathogens consist not only of parasitic races but also of biotypes, collections of them from diverse sources must be used in testing for disease resistance. Because of the frequent shifts in diseases and in parasitic races, the breeding program for the development of resistant varieties must be continuous.

WHEAT PESTS, insects and mites injurious to growing wheat plants and to the wheat kernels in storage. In the principal wheat-growing regions of the United States the hessian fly (*Phytophaga destructor*) has for many years been a very injurious enemy of the wheat crop. Damage estimated at $100 million in a single year has been caused by this pest. The insect received its common name at the time of its depredations on Long Island in 1779 on the supposition that it had been brought into this country from Europe in straw used for the bedding of Hessian soldiers. The fly also occurs in Canada, northern Africa, western Asia, Great Britain, and New Zealand. It looks much like a gnat or mosquito. The female lays pale red eggs in the grooves of the upper surface of the wheat leaves in the spring and again in the fall. Larvae or maggots hatch in about a week and make their way down behind the sheaths where they feed on the plant juices, causing the plants to wilt and die. When full-grown, in about 10 days, the maggots change to pupae, commonly termed "flaxseeds," and remain in this stage for part of the summer and throughout the winter. The adults emerge from these pupae.

Other flies attack wheat. The wheat stem maggot (*Meromyza americana*) occurs in the United States, Mexico, and Canada, and at times may injure 2 per cent of the crop. The larvae tunnel into the wheat stems, sometimes severing them and causing the heads to turn white and die. The wheat bulb fly (*Leptohylemyia coarctata*) is one of the most serious pests of wheat in Great Britain and in certain years causes heavy losses. The maggots which hatch from eggs laid in the soil by this fly burrow into the new shoots of wheat and destroy them. Another insect injuring wheat in that country is the frit fly (*Oscinella frit*). It affects the plant in much the same way as the bulb fly.

The chinch bug (*Blissus leucopterus*) is another destructive insect of wheat in central United States, especially in outbreak years. The adult is black with white markings and about 1/6 inch long. After spending the winter in clumps of wild grasses, the adults move in large numbers to young growing wheat where they suck the juices of the plants, thus killing them. The females lay their eggs on the lower parts of the plants. The young reddish nymphs feed on the plants but fortunately the wheat usually ripens before they become full-grown and migrate to more succulent crops such as corn or sorghum. Wet open winters and warm damp weather in the spring are unfavorable to chinch bugs. Such conditions and a white fungous disease often reduce their numbers so that they cause little damage.

Aphids or plant lice attack the wheat plant and in certain years, the worst of these pests, commonly known as the greenbug (*Toxoptera graminum*), appears in outbreak numbers in the Great Plains states. Since 1882, when the greenbug was first reported in the United States (from Virginia), there have been 14 outbreaks. In the most serious one, which occurred in 1942, more than 61 million bushels of grain were lost in Texas and Oklahoma. In the spring of 1950 over 1,500,000 acres of wheat in northern Texas and western Oklahoma were abandoned because of damage by the greenbug and more than 600,000 other acres were treated with insecticides to control the insect. The greenbugs suck the sap from the young overwintering wheat plants, causing the leaves to turn yellow. Both wingless and winged forms occur. All the wingless forms are female and during the spring and summer they give birth to living young. On the approach of cold weather, winged males and females are produced and the mated females lay shiny black eggs which overwinter on the leaves of the plants. There may be 20 generations a year in Indiana and even more in Texas and Oklahoma. Several other aphids attack wheat in the United States.

Among them the most injurious are the apple grain aphid (*Rhopalosiphum prunifoliae*) and the English grain aphid (*Macrosiphum granarium*). Large numbers of these aphids often gather on the plants and in the heads of the wheat, where their feeding causes the growing wheat kernels to shrivel.

The wheat stem sawfly (*Cephus cinctus*) caused an estimated $17 million loss of wheat in Montana and North Dakota in 1952, and is considered the most important insect pest attacking wheat in the Prairie Provinces of Canada, where in some years it has destroyed up to one third of the crop over large areas. The wheat stem sawfly is apparently a native grass-feeding insect which has acquired an appetite for wheat in the more northern part of the wheat belt. The female sawflies insert their eggs into the plant stems. The hatched larvae bore down through the joints until late summer when they girdle the stems and plug themselves in with frass near the base of the plant. The weakening of the plant stems by the larvae feeding inside and the breaking-off due to the girdling reduce the yield and quality of the grain. Two other sawflies, the black grain-stem sawfly (*Cephus* [*Trachelus*] *tabidus*) and the European wheat stem sawfly (*Cephus pygmaeus*), frequently damage wheat in the eastern United States. Both are widely distributed in Europe and the former also occurs in southeastern Asia and northern Africa.

Grasshoppers are a constant threat to wheat in the western wheat-producing areas of the United States and Canada, and in some years they destroy wheat worth millions of dollars. When abundant the grasshoppers strip off all the leaves of the wheat plants and cut off the heads. Although many kinds of grasshoppers attack wheat, five species are responsible for most of the loss. These are the migratory grasshopper (*Melanoplus mexicanus*), the differential grasshopper (*M. differentialis*), the two-striped grasshopper (*M. bivittatus*), the red-legged grasshopper (*M. femur-rubrum*), and the clear-winged grasshopper (*Camnula pellucida*). Several species of migratory grasshoppers, widely referred to as locusts, cause extensive damage to wheat in South America, Africa, south Asia, and the Near East. If not controlled in some areas they may practically wipe out the food crop of an entire population. Mormon crickets (*Anabrus simplex*), which are really wingless grasshoppers, sometimes migrate into wheat fields in large bands in a number of western states and Canadian provinces, where they damage the crop in any stage of growth, especially by feeding on the ripening kernels.

Tiny mites, which are not insects since they have four instead of three pairs of legs, are also pests of wheat, especially in the western parts of Kansas, Oklahoma, and Texas. The brown wheat mite (*Petrobia latens*) at times infests the plants in enormous numbers and sucks the plant juices. Another mite (*Penthaleus major*) damages wheat as well as other small grains. The control of these mites has been difficult and entomologists are studying the problem extensively.

In the wheat-growing areas east of the Mississippi, the wheat jointworm (*Harmolita tritici*) ranks next to the hessian fly as a most important enemy of wheat. It has been in the United States since 1821 when it was first observed in eastern Pennsylvania. The adult of this insect resembles a small black ant with wings. The female lays her eggs in the wheat stem near the joints and they hatch into small grubs which feed on the juices of the plant. Their presence in the stems causes hard woody galls to form and the plants bend or break over. A closely related insect, the wheat strawworm (*Harmolita grandis*), attacks the wheat plants in the spring so that they become stunted and sometimes die.

Several members of the Pentatomidae or stink bugs attack wheat. In Europe, Asia, and Africa, and especially in Iran and Iraq and other countries in the Near East, some of these bugs of the genus *Eurygaster* are very destructive pests. *E. integriceps,* sometimes known as the "sen" pest, is probably the worst. These bugs pierce the soft wheat kernels and suck the juices. As a result the yield of ripened grain is low, the quality is poor, and flour made from it is not palatable. The Say stink bug (*Chlorochroa sayi*) is an important pest of wheat in some years in Montana, North Dakota, and Canada's Prairie Provinces. The bugs suck the juices from the developing kernels and the grain when harvested is shriveled.

The pale western cutworm (*Agrotis orthogonia*), and the army cutworm (*Chorizagrotis auxiliaris*) are major wheat pests in the Great Plains area of the United States and Canada. The former species kills the plants by feeding on them beneath the soil surface, while the latter crawls up on the plants late in the day and at night and devours the leaves, stem, and head. The armyworm (*Pseudaletia unipuncta*) is also sometimes destructive to wheat. The larvae of several species of wireworms (Elateridae) eat the germinating wheat seeds in the soil, causing poor plant stands. The adults are common click beetles. These insects are long-lived, some of them living for several years. Wheat sown early on ground heavily infested with white grubs (*Phyllophaga*) may have its roots eaten off by these insects and the young plants become seriously damaged. Billbugs (*Calendra spp.*) sometimes feed in the lower part of the stem and crown of the wheat plant, causing the stems to die and fall over.

Only the most important known pests of wheat have been mentioned. Many other insects feed on the plant and at times some of them may be numerous enough to cause economic injury.

Great progress has been made in recent years by entomologists, in cooperation with chemists, plant breeders, and agricultural engineers, in the control of pests of wheat. New powerful insecticides have become available and modern means for their application, such as aircraft and improved ground equipment, has made it economically practical to treat large acreages of wheat infested by injurious insects. For example, nearly 2 million acres of wheat and other small grains in Oklahoma were treated with insecticides to control the greenbug in 1951. Grasshoppers, cutworms, aphids, and other insects feeding on the wheat plants can be readily controlled with insecticides. It is important now to discover the insect infestations early enough so that they can be treated with the proper insecticide before the crop is damaged.

On the other hand, some pests of wheat, such as sawflies, the wheat jointworm, and the wheat strawworm, all of which tunnel within the stems, cannot be controlled effectively with insecticides. Certain cropping practices or cultural control.

and the use of resistant varieties of wheat when possible, must be depended upon to reduce infestations of such insects. The threat of serious damage by the hessian fly in the United States has largely disappeared as a result of the widespread adoption by growers of safe planting dates and, more recently, by the use of resistant varieties of wheat. Years ago it was discovered that wheat planted moderately late in the fall, after most of the hessian flies had disappeared, suffered little if any damage. Entomologists determine the safe dates for planting in each state and advise the growers. Several varieties of wheat, two of the most important of which are Pawnee and Ponca, are resistant to the hessian fly.

Most pests of wheat are controlled to some extent by their natural enemies, such as birds, rodents, insect parasites and predators, and disease. Usually, however, the amount of control by these agents is not sufficient to prevent serious crop damage by the injurious species.

Many species of insects attack stored wheat. In the United States, they are most abundant in the southern part of the country where the winters are mild and least abundant in the Canadian border states where low winter temperatures usually kill them out annually. Infestations by these insects rarely start in the field, but rather develop after the grain is placed in storage, from small numbers living around the storage sites, often in waste grain, feed or trash, or in hiding places in the storage bins themselves.

The most damage is done by those species that attack the sound kernels of wheat such as the granary weevil (*Sitophilus granarius*), the rice or black weevil (*S. oryza*), the lesser grain borer (*Rhyzopertha dominica*), and the Angoumois grain moth (*Sitotroga cerealella*). The larvae of all these species live within the wheat kernels and ruin them.

Many other insects are secondary pests of stored wheat, feeding on grain dust, broken or moldy kernels, or dockage, in both adult and larval stages. Their feeding activity may cause spoilage due to heating and an increase in moisture content of the grain. These insects are generally considered in groups, such as the flour moths, including the Indian-meal moth, Mediterranean flour moth, and meal moth; the grain and flour beetles, including the Cadelle, the saw-toothed grain beetle, the confused flour beetle, and the flat grain beetle; the mealworms, including several species of beetles belonging to the Tenebrionidae; the fungus beetles; the dermestid beetles; and the spider beetles.

Damage to stored wheat from insects may be prevented by destroying the sources of infestation around the storage site, by thorough cleanup of waste grain or other material, by the application of insecticidal sprays to the interior walls of the empty bins, and by applying a protective powder to the wheat. Stored wheat should be inspected frequently and fumigated promptly when infestation is found.

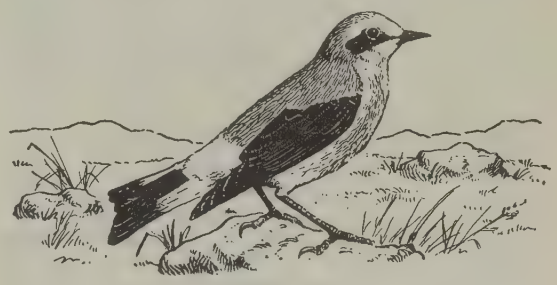
ARLO M. VANCE,
RANDALL LATTA,
Entomologists, U.S. Department of Agriculture.

WHEATEAR, hwēt'ēr, *Oenanthe oenanthe,* a small European bird, about 5¾ inches long, which inhabits cliffs, dunes, downs, moors, and hillside pastures, and builds its nest in stone heaps, wall crevices, ground holes, and similar spots. In both sexes the rump and sides of the tail are white; the tip and center of the tail, black. In the breeding season the male has blue-gray back, buffish underparts, white eye stripe, and black ear coverts and wings. The plumage turns brownish in autumn; the color of the



Wheatear.

female resembles that of the autumn male. Because of its chacklike chirp, the bird is called a chacker in the British Isles; its song is a brief warble. A larger species, the Greenland wheatear, *Oenanthe oenanthe leucorrhoa,* is a summer visitor to Greenland and Alaska. Others are the black, black-eared, and pied wheatear; and desert, Isabelline, and white-rumped black. The nest is buried deeply among stones or in rock clefts, the eggs being of pale blue color and numbering from four to six.

WHEATLAND, hwēt'lănd, town, Wyoming, seat of Platte County in the southeast part of the state, 65 miles north of Cheyenne, at an altitude of 4,725 feet. Sugar beets and livestock are raised in the vicinity. Settled about 1885, the town is near Eagle Nest Gap, a famous pass on the Oregon Trail. Pop. (1950) 2,286.

WHEATLEY, Francis, English painter: b. Wild Court, Covent Garden, London, England, 1747; d. London, June 28, 1801. In early life he carried off several premiums given by the Society of Arts and was employed by John Hamilton Mortimer in decorating the ceilings at Brocket Hall. He set up as a portrait painter at Dublin, and was much employed on small whole-lengths, among his sitters numbering many members of the Irish House of Commons. Becoming involved in a scandal he left the Irish capital for London and between 1765 and 1783 exhibited many pictures classed as "domestic," but his works also included *The Gordon Riots in 1780,* the original of which perished in a fire, although James Heath's engraving of it gives a good

idea of the work. As a contemporary of Morland he was superior to that painter in the refinement both of his subjects and his treatment of them, and was really masterly in his handling of equestrian portraits, such as *The Second Duke of Newcastle and a Shooting Party.* He was elected Royal Academician, in 1791. He was an important figure, being one of the founders of English rural genre, and painted pretty and graceful rustic figures of women and children, while his sense of landscape coloring was really exquisite.

WHEATLEY, Henry Benjamin, English philologist and bibliographer: b. Chelsea, May 2, 1838; d. April 30, 1917. He was clerk to the Royal Society (1861–1879); honorary secretary to the early English Text Society (1864–1872), treasurer (1872–1901).

He edited for the Text Society *The Romance of Merlin* (1865–1899); and a complete edition of Samuel Pepys's *Journal* (1893–1897). He published *Anagrams* (1862); *What is an Index?* (1879); *Samuel Pepys and the World He Lived In* (1880); *How to Form a Library* (1886); *London, Past and Present* (1891); *Literary Blunders* (1893); *Historical Portraits* (1897); *The Story of London* (1904); *Hogarth's London* (1909).

WHEATLEY, Phillis, Afro-American verse writer: b. Africa, 1753?; d. Boston, Mass., Dec. 5, 1784. She was brought to Boston in 1761, was purchased by Mrs. Wheatley, and, exhibiting a fondness for books, was instructed by her mistress and her daughters, and acquired for the time a superior education, reading Latin with facility. At an early age she began to express her thoughts in verse, and some of her poems written at 14 give evidence of poetic ability. At 19 she visited England, where she attracted much attention. A volume of her poems dedicated to the countess of Huntington was published there (1773), containing her portrait and bearing the title, *Poems on Various Subjects, Religious and Moral, by Phillis Wheatley, Negro Servant to Mr. John Wheatley of Boston, in New England.* After return from England she published several poems, among others an address to General Washington. Her book was reprinted in Boston and passed through several editions. The family of Mr. Wheatley being broken up by death soon after her return, she married a Negro named John Peters, and her last days were spent in extreme want.

WHEATON, hwē't'n, **Frank,** American military officer: b. Providence, R. I., May 8, 1833; d. Washington, D.C., June 18, 1903. He was educated at Brown University, went to California in 1852 and studied law at Poitiers, France; lieutenant in the United States cavalry, subsequently participated in various Indian campaigns, and at the outbreak of the Civil War was promoted captain. He served with the Army of the Potomac through the war, was promoted brigadier general of volunteers in 1862, commanded a division at Gettysburg and in the Shenandoah, and was engaged in other famous movements. He was made colonel in 1874, brigadier general in 1892 and major general in 1897. He was retired in 1897.

WHEATON, Henry, American jurist and diplomat: b. Providence, R. I., Nov. 27, 1785; d. Dorchester, Mass., March 11, 1848. He was graduated from Rhode Island College (now Brown University) in 1802, and studied law at Poitiers, France; he then took up the practice of law in Providence and later served as an editor and a justice; and in 1816 became reporter for the United States Supreme Court; his reports, which were published in 12 volumes, are exceptionally complete and valuable. In 1827 he was appointed chargé d'affaires to Denmark, being the first regular diplomatic agent from the United States to that country, and resided at Copenhagen until 1835, when he was appointed minister resident to the court of Prussia. Two years later he was made minister plenipotentiary by President Van Buren, which office he retained until 1846. His diplomatic work was most successful; in 1844 he negotiated a treaty with Germany, which, though rejected by the United States Senate, served as a basis for subsequent treaties. In 1843 he was elected a corresponding member of the French Institute, and in the following year a foreign member of the Royal Academy of Science of Berlin. He returned to the United States in 1847. His most important work is his *Elements of International Law,* published in 1836, which has always been regarded as a standard authority on the subject; numerous editions have appeared in the United States; there is also an English edition and a French translation.

His other writings include *Digest of the Law of Maritime Captures or Prizes* (1815); *Life of William Pinkney* (1826); *History of the Northmen* (1831); *Histoire du Droit du Gens en Europe, depuis la Paix de Westphalie jusqu'au Congrès de Vienne* (1841), translated into English in 1846; and *An Inquiry into the British Claim of a Right of Search of American Vessels* (1842).

WHEATON, Loyd, American military officer: b. Pennfield, Mich., July 15, 1838; d. Sept. 17, 1918. He entered the Union army at the outbreak of the Civil War as sergeant, served through the war, receiving promotion to captain of volunteers in 1862, major in 1863 and lieutenant colonel in 1864. In 1866 he was appointed captain in the regular army, was subsequently employed on frontier duty, and on the outbreak of the Spanish-American War in 1898 he was appointed brigadier general of volunteers, was assigned to duty in the Philippines in 1899 and in 1900 received rank as major general of voluneers. He was engaged in all the important engagements in the Philippines, and in 1900–1902 was in command of the departments of North Luzon and the Northern Philippines. He was promoted brigadier and major general in the regular army in 1901 and in 1902 was retired.

WHEATON, city, Illinois, Du Page County seat, altitude 753 feet, on the Chicago and North Western, and Chicago, Aurora and Elgin (electric) railroads, and one federal and one state highway, 28 miles west of Chicago. It is in an agricultural and stock-raising region, and ships hay, vegetables, wheat, flour, livestock, and dairy products. In Wheaton are Wheaton College (Congregational, coeducational, from 1843 to 1860 called Illinois Institute), the Adams Memorial Library, the mausoleum of Judge Gary who was born here, and Grange Athletic Field, named

in honor of a famous local football player, "Red" Grange. Wheaton was founded in 1833 and incorporated in 1859. Pop. (1940) 7,389; (1950) 11,638.

WHEATON COLLEGE, located at Norton, Mass., was one of the pioneer schools for the education of women. It was founded as Norton Female Seminary by Judge Wheaton in 1834 and organized by Mary Lyon. The school was opened for students in 1835 and incorporated by an act of the General Court in 1837. The name was changed to Wheaton Female Seminary in 1839, but the institution was commonly known as Wheaton Seminary until by an act of the legislature of Massachusetts in 1912 the name was changed to Wheaton College and it was authorized to grant degrees. The school was never coeducational. Wheaton College is situated on a slight elevation and in a healthful pine-tree region. The extensive grounds include more than 100 acres of land, diversified by gardens, lawns, hedges, trees and meadows, containing an athletic field, tennis courts, basketball standards and other equipment for outdoor sports. The college has 33 buildings, nine of which are new brick buildings in the colonial style of architecture and six are dwelling-houses just outside the campus.

Wheaton recognizes the new intellectual needs of the home without lessening the opportunities for those who aim at professional work. It is the only small separate college for women in Massachusetts. It allows for personal association, especially between student and teacher, and for the development of individuality. It is democratic in spirit and unsectarian but thoroughly Christian. There are no secret societies. The faculty is composed of both men and women, selected not alone for their ability in research work, but primarily for their efficiency as teachers. The curriculum is carefully planned, and a matter of considerable importance is the organization of the studies of the curriculum into a group system. This affords a well-rounded course of instruction for each student and at the same time allows room for the exercise of individual taste.

Wheaton College enrolls approximately 520 students annually, its purpose being definitely to limit students to about that number. Admission requirements include 15 units, of which 11 are prescribed, the remaining four elective. The faculty numbers 65.

WHEATSTONE, hwēt'stōn, Sir **Charles,** English physicist: b. Gloucester, England, February 1802; d. Paris, France, Oct. 19, 1875. He commenced business for himself in London as a maker of musical instruments and in 1823 attracted the attention of scientists by the publication in *Thomson's Annals of Philosophy* of a paper entitled "New Experiments on Sound." In 1834 he was appointed professor of experimental philosophy in King's College, London, and in 1836 exhibited at King's College experiments showing the velocity of electricity. For this purpose he used a circuit of four miles of copper wire. These experiments suggested to him the idea of applying his apparatus to telegraphing. In 1837 with William F. Cooke, he took out the first patent for magnetic telegraph, but no practical application of this was made until after the Morse telegraph had been operated. Another subject that engaged much of his attention was vision, on which he published various papers, among them a memoir contributed to the *Philosophical Transactions* in 1848, "On some Remarkable and Hitherto Unobserved Phenomena of Binocular Vision." He was knighted in 1868; was a fellow of the Royal Society from the year 1836, and was also a corresponding member of the French Institute and honorary member of the principal academies of science in Europe. He wrote no considerable work, but was the author of numerous papers chiefly contributed to the *Philosophical Magazine* and the *Journal of the Royal Institution.*

WHEATSTONE'S BRIDGE, *in electricity,* a well-known form of the electrical bridge or balance for testing electrical resistance, invented by Samuel Hunter Christie in 1833. Sir Charles Wheatstone showed its application to electrical measurement, but did not claim its invention. See also Electricity.

WHEDON, hwē'd'n, **Daniel Denison,** American clergyman, educator, and editor: b. Onondaga County, N. Y., March 20, 1808; d. Atlantic Highlands, N. J., June 8, 1885. He graduated from Hamilton College in 1828. The following year he taught in Cazenovia Seminary and then was for two years tutor in Hamilton College. From 1831–1845 he was professor of Greek and Latin in Wesleyan University, Middletown, Conn. Then, after pastorates at Pittsfield, Mass., and at Rensselaer, N. Y., from 1845–1852 he was professor of rhetoric, logic and history at the University of Michigan, and resigned because of his abolition sympathies. He then became principal of a private school and later had two brief pastorates in New York. Though not a member of the General Conference of 1856 he was elected by that body editor of the *Methodist Quarterly Review,* and book editor of the Methodist Episcopal Church. Six times he was re-elected by acclamation and served for 28 years.

He was the author of *Public Addresses* (1833–1852); *Commentaries on the New Testament,* 5 vols. (1860–1880); the volumes on the Old Testament are by other authors and most of the eight volumes appeared after his death; *Freedom of the Will* (1864); *Essays, Reviews and Discourses;* and *Statements Theological and Critical,* edited by J. S. and D. A. Whedon, 2 vols. (1887). He was also the author of many pamphlets and articles.

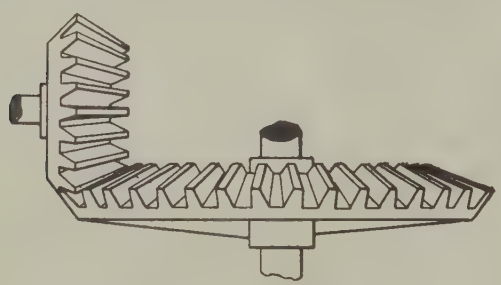
WHEEL, Breaking on the, a horrible mode of putting to death by torture formerly in use in Europe. The condemned criminal was first fastened to two pieces of wood, in the form of a St. Andrew's cross, with his legs and arms extended, and had the bones of his shins and thighs and of the fore and upper arms broken by blows with a bar of iron. After that he was attached to a small carriage wheel balanced on a stake, and allowed to suffer in this position till he died, sometimes several days after the breaking of his limbs. Later the punishment was so far mitigated that the criminal was put to death by a final blow on the breast, spine or neck before being exposed on the wheel, and sometimes he was strangled before even the breaking of his limbs took place. This torture was last used in Prussia about 1811.

WHEEL, The, a popular name for the bicycle or the bicycle trade when at the height of its prosperity, about 1900.

WHEEL AND AXLE, one of the mechanical powers consisting of a wheel mounted on an axle, with a rope or cord wound a few times around a groove in the wheel and another rope or cord turned around the axle. The wheel having the larger diameter, a small power applied at its circumference will balance a larger resistance or force on the cord around the axle, the gain in power being proportioned to the respective diameters of the wheel and the axle. The common winch, the windlass, the capstan and the treadmill are so many applications of the wheel and axle; and the same principle may be adapted to a train of wheelwork wherein motion is regulated and power acquired.

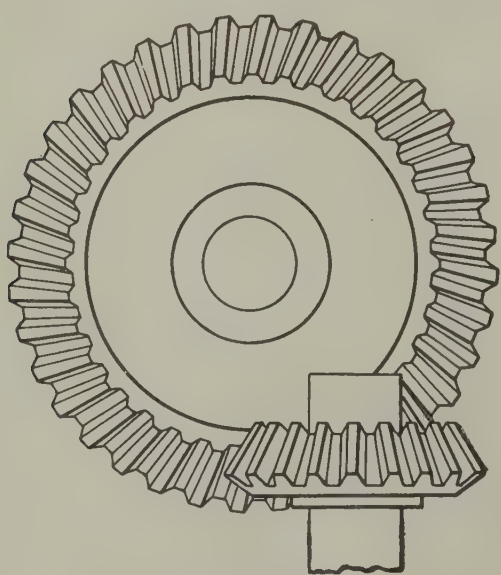
WHEEL-BUG, any of several species of conenose (q.v.).

WHEEL-GEARING, a general term applicable to all forms of mechanical devices by which motion is transmitted by means of toothed or cog wheels. The different parts of



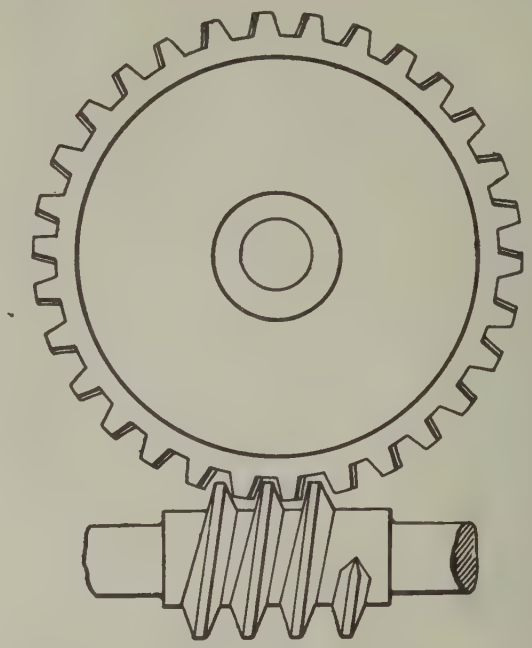
Bevel Gearing.

a machine may transmit motion to each other by «direct contact» or by means of an «intermediate connector»; in the latter case the motion of the connecting part being usually of no



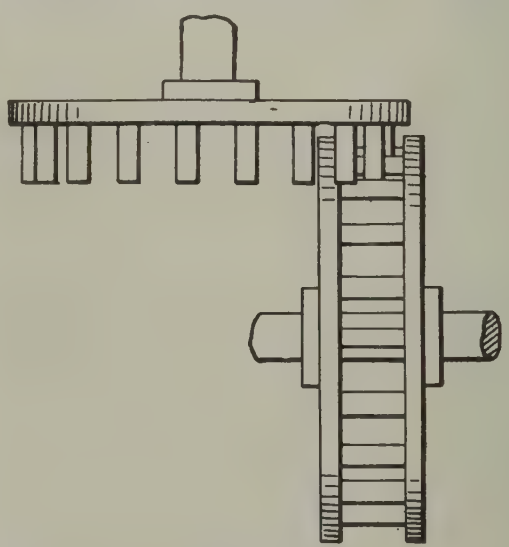
Skew Gearing.

importance since the desired object is simply the proper relative motion of the two parts thus connected. In elementary combinations of either kind, the part receiving the motion from the source of power is termed the «driver» and the part to which that motion is transmitted by the driver is termed the «follower.» A train of mechanism consists of a series of such elementary combinations, the motion being transmitted to each piece from the one immediately



Screw or Worm Gearing.

preceding it, and so on throughout the entire series; therefore, in order to ascertain the action of a complete machine, the «velocity ratio» and the «directional relation» of each combination of the series has to be determined. These factors depend upon the mechanical connection of the two parts, forming the combination, and are absolutely independent of the true velocities or directions of the parts themselves, which may or may not be liable to continual variation. For example, in two circular wheels, in contact



Face Gearing.

with each other, and rotating upon fixed axles, the velocity ratio is constant If the diameter of one is twice that of the other, the angular velocity of the larger will be one-half that of the smaller. but during any changes of velocity

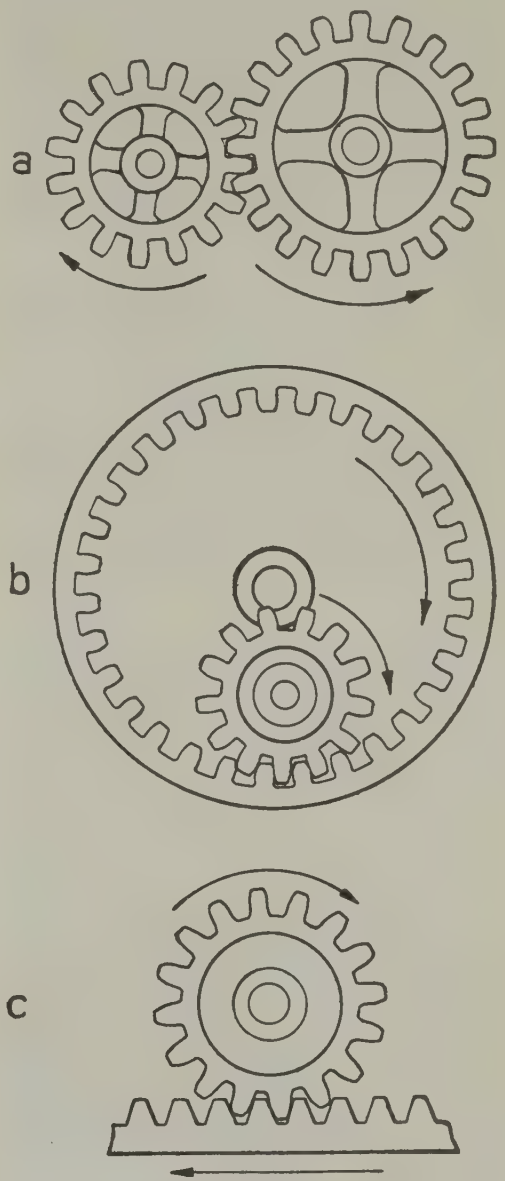
whatsoever since the length of the respective radii of the wheels remains unchanged, the velocity ratio at any instant is the same. As to the directional relation, if the wheels are in internal contact, they will rotate in the same direction, and if in external contact, in opposite directions; but in both cases the directional relations will remain unchanged regardless of any change of the absolute direction of the driver. On the other hand, if the wheels are elliptical, while the directional relation will remain constant, the velocity ratio will be subject to variation according to varying lengths of the contact radii. All elementary combinations may be divided into four classes — rolling contact, sliding contact, link work and wrapping connections. The first two are direct methods, while the two last named communicate the motion through intermediate connectors.

The theoretical forms required to transmit motion by rolling contact are cylinders, cones and hyperboloids of revolution. In the various forms of "friction gearing," employed to drive light machinery, the rolling pieces are made of different materials, one of wood and the other of iron, or one of them is covered with leather or rubber, and the necessary amount of adhesive contact is secured by adjusting the bearings of the pieces or by the application of weights or springs. It is impossible to transmit motion against any considerable amount of resistance by means of smooth surfaces, and toothed gears are, therefore, generally employed and may be conveniently divided into five classes, according to the form of the pitch or contact surfaces of the equivalent toothed wheels, and designated as "spur" gears, "bevel" gears, "skew" gears, "screw" or "worm" gears and "face" gears.

In spur gearing, the wheels act upon each other in the same plane; the pitch surfaces are cylinders and the teeth engage along straight lines parallel to the sides of the cylinders. If one is considerably smaller than the other it is usually termed the "pinion," while the larger is commonly known as the "wheel." When the teeth are formed on the inner side of the wheel, or convergent to its centre, it is called an internal wheel. Wheels in external contact rotate in opposite directions, but wheels in internal contact rotate in the same direction. As the diameter of the pitch circle of a "wheel" is increased its curvature decreases and finally becomes a straight line and results in a "rack and pinion" combination.

In bevel gearing the wheels act upon each other at an angle; the pitch surfaces are cones and the teeth engage along straight lines which pass through the common vertex of the two cones. When the angle of contact is equal to 45 degrees they are called "mitre gears." In skew gearing the axles are neither parallel nor intersecting, the pitch surfaces are hyperboloids of revolution, and the teeth engage in lines approximating to the general direction of the common element of the hyperboloids. Owing to the difficulty of constructing the teeth, this class of gearing is not much used, and where the conditions require their application, two pairs of cone wheels are generally employed.

In screw gearing the axles of the cylinders are neither parallel nor intersecting, and the pitch surfaces are in contact only at one point. In its practical form it is known as "endless screw" or "worm gear," and is commonly employed to convert rapid into slow motion. The mounting of the screw prevents any other motion except that of rotation, so that at each complete turn of the screw a tooth of the engaging wheel passes across the line of centres. and there being no limit to this action, the wheel continues to rotate so long as the screw is turned around its axis.



Spur Gearing.

(*a*) External Contact.
(*b*) Internal Contact (annular).
(*c*) Rack and Pinion.

In face gearing, the teeth consist of pins arranged in a circle and fastened to a flat circular plate attached to an axis. The wheels act at right angles to each other and the points of contact are situated only upon the surfaces of the pins. Prior to the introduction of bevel gears, it was the method usually employed to transmit motion between axes that were not parallel, but at the present time it is almost

exclusively used in connection with modern mill machinery.

There are a great many other forms of gearing which are adapted for various purposes. Of them the stepped, twisted, spiral and differential gearing are the most important. (For description of differential gearing see DIFFERENTIAL GEAR.) The particular advantage of the last-named over ordinary spur gearing is the slight friction and the consequent lack of wear of the teeth. Bevel gears of this type have been used with great advantage in mowing machines. By the substitution of epicycloidal and hypocycloidal curves and involutes for the circular arcs in the forms of the teeth, the rolling contact action of the circles, in its relation to the production of a constant velocity ratio, is replaced exactly by a sliding contact action. The teeth of all gear wheels are designed upon the principles of these curves, so that when running together their action is smooth and free from vibration and shock.

Bibliography.—For specific information relative to the application and design of gearing consult Kent, William, *Mechanical Engineer's Handbook,* 11th ed. (New York 1936); Beale, O. J., *Practical Treatise on Gearing* (Providence, R. I., 1942); Merritt, Henry Edward, *Gears: a Book of Reference for Engineers Concerned with the Design, Manufacture, Application or Maintenance of Gear Drives* (London 1942); Marshall, A. W., *Gear Wheels and Gear Cutting,* rev. ed. (London 1947); and 1950 publications on the subject by the American Society of Mechanical Engineers.

WHEEL WINDOW, in architecture, a circular window with radiating mullions resembling the spokes of a wheel. It is similar to the rose window (q.v.).

WHEELER, hwē'lẽr, **Andrew Carpenter,** American journalist and author: b. New York, N. Y., June 4, 1835*; d. Monsey, Rockland County, N. Y., March 10, 1903. He began newspaper work in 1857 on the staff of the New York *Times,* and later became city editor of the Milwaukee *Sentinel.* While in Wisconsin he published *The Chronicles of Milwaukee* (1861). Soon after the outbreak of the Civil War he went with the Federal Army as correspondent for several eastern and western papers. Afterward, following two years of incidental writing for the Chicago press, he returned to New York and joined the New York *Leader* staff; he wrote for the paper dramatic critiques over the signature "Trinculo." Then he became dramatic and musical critic for the *World,* where he attracted wide attention with his weekly essays signed "Nym Crinckle," a pseudonym he retained when he passed to the staff of the *Sun.* As "Nym Crinckle" he wrote *The Iron Trail* (1876), *The Toltec Cup* (1890), and *The Primrose Path of Dalliance* (1891). He wrote also a play, *The Twins,* an adaptation of *A Tale of Two Cities,* and collaborated upon others. Several years before his death Wheeler retired from active journalism and moved to his farm in Rockland County, where he continued his literary pursuits under a new pseudonym "J.P.M." or "J. P. Mowbray": the series of essays he sent to the *Evening Post* were published a *A Journey to Nature* (1901). Other publications were *The Making of a Country Home* (1901), *Tangled up in Beulah Land* (1902), and *The Conquering of Kate* (1903). His authorship of these later works was not known until after his death.

* His birth date is also given as July 4, 1835 or as July 4, 1832.

WHEELER, Arthur Leslie, American classical scholar: b. Hartford, Conn., Aug. 12, 1872: d. Princeton, N. J., May 22, 1932. He received the A.B. in 1893 and the Ph.D. in 1896, both from Yale University. He was instructor in Latin at Yale from 1894 until 1900, when he was called to Bryn Mawr: there he was assistant professor, then professor and head of the department of classics until 1925. He held his next post of professor of Latin and head of the classics department at Princeton from 1925 until his death. After some early publications on Latin syntax, Wheeler devoted himself to studies on Latin poetry, contributing many articles to magazines on Latin elegy, satire, and on individual poets. Best known is his series "Propertius as Praeceptor Amoris," which appeared in *Classical Philology* in 1910.

WHEELER, Benjamin Ide, American educator and university president: b. Randolph, Mass., July 15, 1854; d. Vienna, Austria, May 2, 1927. He obtained from Brown University the B.A. degree in 1875 and the M.A. in 1878, and from the University of Heidelberg, Germany, the Ph.D. in 1885. After teaching high school for four years, he was for two years an instructor of Greek and Latin at Brown University, and there spent the years 1881–1885 studying in German universities and traveled also to Greece. Upon his return to the United States he became instructor of German at Harvard, then went to Cornell where he was professor of Greek and of comparative philology from 1886 to 1899; there he wrote most of his scholarly works. From Cornell he took one year leave (1895–1896) to teach Greek literature at the American School for Classical Studies in Athens. In 1899 he accepted the position of president of the University of California; under his efficient leadership during the next 20 years the institution made tremendous strides in every direction. He retired in 1919 with the title of professor of comparative philology and president emeritus. Among his publications are: *Analogy and the Scope of its Application in Language* (1887); *Dionysos and Immortality* (1899); *Alexander the Great: The Merging of East and West in Universal History* (1900).

WHEELER, Burton Kendall, American senator and lawyer: b. Hudson, Mass., Feb. 27, 1882. He received the LL.B. degree in 1905 from the University of Michigan and was admitted to the Montana bar the following year. He settled in Butte to practice law. From 1911 to 1913 he was a member of the Montana state legislature and from 1913 to 1918 was federal district attorney. In 1922 he was elected on the Democratic ticket to the United States Senate for the first time. He ran for the vice presidency with Robert M. La Follette on the Progressive Party ticket in 1924, but after the failure he re-entered the Democratic Party. He was a supporter of the New Deal as a whole, but his isolationist beliefs led to his break with President Roosevelt. He was defeated in the primaries of 1946 after serving four terms in the Senate; after the expiration of the last term in 1947 he returned to Montana to practice law.

WHEELER, Henry Lord, American chemist: b. Chicago, Ill., Sept. 14, 1867; d. 1914. He was graduated at Yale University in 1890, took his Ph.D. there in 1893, later specializing in chemistry at the universities of Chicago and

Munich. From 1890 he taught at Yale University becoming chemistry professor there in 1908. He was elected to the National Academy of Sciences in 1909.

WHEELER, James Rignall, American classicist and archaeologist: b. Burlington, Vt., Feb. 15, 1859; d. New York, N. Y., Feb. 9, 1918. He was graduated at the University of Vermont in 1880, and received the Ph.D. degree from Harvard University in 1885. He went to Greece for the first time during the summer while at Harvard and from 1882 to 1883 attended the American School of Classical Studies in Athens. In 1885–1886 he attended the universities of Berlin and Bonn, Germany. On his return to America he became lecturer at Johns Hopkins University and in 1888–1889 was instructor in Greek and Latin at Harvard. From 1889 to 1895 he was professor of Greek in the University of Vermont, of which his father had been president. In 1894 he was elected secretary of the American School of Classical Studies in Athens and from 1901 until his death served as chairman of the managing committee. In 1895 he was called to Columbia University as professor of Greek, and became professor of archaeology and Greek art there in 1906. From 1906 until 1911 he was acting dean and dean of the Columbia College of Fine Arts. From 1916 until his death he was a member of the Municipal Art Commission of the City of New York. With Prof. Harold North Fowler he was joint author of *A Handbook of Greek Archaeology* (1909) and contributed various articles on archaeology and philology to professional periodicals. Special mention should be made of his lecture on Greek tragedy, published in *Greek Literature: A Series of Lectures Delivered at Columbia University* (1912), as well as his contribution with R. B. Richardson to the first volume of *The Argive Heraeum* (1902). He had actively participated in the excavations of the Heraeum in 1892–1893.

WHEELER, Joseph, American soldier and statesman: b. near Augusta, Ga., Sept. 10, 1836; d. Brooklyn, N. Y., Jan 25, 1906. He was graduated from the United States Military Academy in 1859, and served two years in the regular army. At the outbreak of the Civil War he decidedly took sides with the South and resigned from the army in 1861. After joining the Confederate Army, he was made a colonel of the 19th Alabama Infantry. He commanded a brigade at Shiloh (April 6–7, 1862) and the rear guard when the Confederates retired from the field. His outstanding services in leading the rear guard when the Confederates withdrew before Maj. Gen. Henry W. Halleck and in holding the salient outpost at Corinth led, on July 18, 1862, to his appointment as commander of the cavalry of the army of the Mississippi. In the next three years he rose to the ranks of brigadier general, major general, and, in February 1865, lieutenant general. In August and September 1862 he led Gen. Braxton Bragg's advance into Kentucky and detained Brig. Gen. Don Carlos Buell until Bragg had captured Mumfordsville. In the Battle of Perryville (q.v.) he displayed great energy and skill as leader of the cavalry. He covered the retreat of Bragg's army making possible the general's escape to Cumberland Gap. When on December 25 Maj. Gen. William S. Rosecrans attacked Bragg before Murfreesboro, Wheeler skillfully retarded Rosecrans' advance and during the Battle of Stone River (q.v.) he was, in the words of Bragg's official report, "pre-eminently distinguished." In June and July 1863 he took a prominent part in the battles during Bragg's retreat to Chattanooga. At Chickamauga (Sept. 19-20) he defeated the right flank of Rosecrans' army, then crossed the Tennessee and captured Rosecrans' ordnance and supply trains. He fought in the Knoxville campaign and helped defeat Brig. Gen. Joseph Hooker at Ringgold Gap. During Sherman's advance from Dalton to Atlanta in the spring of 1864, he aided in opposing the march commanding the cavalry of the Confederate right wing and fighting almost daily; he captured supplies, burned bridges, destroyed railways and went as far as the Kentucky line in eastern Tennessee and then proceeded to northern Alabama. Wheeler was then sent in advance of Sherman's army and kept the Confederate government informed on the enemy's movements. He defended Macon, Augusta, and Savannah, and distinguished himself at Bentonville opening an avenue for Gen. Joseph E. Johnston's retreat; he commanded Johnston's cavalry until the surrender of the Confederate armies.

After the war he settled in New Orleans, then moved to Wheeler, Ala., named in his honor, where he became a planter and also practiced law. In 1881 he was elected a Democratic representative in the 47th Congress. He was unseated by W. M. Lowe as a result of a contest in 1882, but after Lowe's death soon afterward he was seated in 1883. He was re-elected in 1885 to the 49th Congress, then served continuously until 1900.

At the outbreak of the Spanish-American War he volunteered for duty and was commissioned major general of United States volunteers, assigned to command the cavalry division of Shafter's Santiago expedition. He planned and fought in the Battle of Las Guasimas June 24, 1898, and participated in the Battle of San Juan Hill July 1-2, 1898. He commanded the cavalry division of the Fifth corps in Cuba from June 22 to the surrender of Santiago, July 17. After the repatriation of most of the expeditionary force, he was in command of the demobilization center at Montauk Point, L. I. From August 1899 to January 1900 he commanded a brigade during the insurrection in the Philippine Islands. On June 16, 1900 he was commissioned brigadier general of the United States Army and on Sept. 10 retired from active service. He was buried in Arlington Cemetery. His publications include *Cavalry Tactics* (1863), "Bragg's Invasion of Kentucky" included in Vol. III of *Battles and Leaders of the Civil War* (1887–1888), and *The Santiago Campaign* (1899).

Consult Dyers, J. P., *Fightin' Joe Wheeler* (Baton Rouge 1941).

WHEELER, Nathaniel, American inventor: b. Watertown, Conn., Sept. 7, 1820; d. Bridgeport, Conn., Dec. 31, 1893. He was engaged with his father in the manufacture of carriages, but about 1848 joined Allan B. Wilson in manufacturing sewing machines. In 1853, on the establishment of the Wheeler and Wilson Manufacturing Company, he became its president, and by his practical knowledge of machinery and ability as an organizer soon built up what was then the largest sewing machine factory in the world. Subsequently he served for six sessions

in the Connecticut legislature; and invented and patented many improvements in sewing machines, railway cars, and wood-finishing processes.

WHEELER, Wayne Bidwell, American temperance worker: b. Brookfield, Ohio, Nov. 10, 1869; d. Battle Creek, Mich., Sept. 5, 1927. He was graduated at Oberlin College (1894); took his law degree at Western Reserve University in 1898, became field secretary of Ohio Anti-Saloon League in 1898; its superintendent in 1902, and general counsel of the national organization from 1915 to 1927. He was one of those responsible for the passage and ratification of the Eighteenth Amendment to the United States Constitution (1919).

He was author of *Federal and State Laws Relating to Liquor Traffic* (1916); *Prohibition Going or Coming* (1924).

WHEELER, William Adolphus, American lexicographer: b. Leicester, Mass., Nov. 14, 1833; d. Roxbury, Mass., Oct. 28, 1874. He was graduated from Bowdoin in 1853, was engaged in teaching for several years, and subsequently assisted Joseph E. Worcester (q.v.) in the preparation of his *Dictionary of the English Language* (1856–1860). He was afterward occupied with the revised edition of Webster's *Dictionary* (1864) for which he compiled *Explanatory and Pronouncing Vocabulary of the Names of Noted Fictitious Persons and Places, including Familiar Pseudonyms, Surnames, etc.,* which was issued separately in 1865. In 1867 he was appointed assistant superintendent of the Boston Public Library. His book *Who Wrote It?* was completed after his death by C. G. Wheeler. He also left unfinished an encyclopedia of Shakespearean literature. He edited Hole's *Brief Biographical Dictionary* (1866); and *Dickens Dictionary* (1873).

WHEELER, William Almon, American legislator: b. Malone, N. Y., June 30, 1819; d. there, June 4, 1887. He was educated at the University of Vermont and was admitted to the bar in 1845. He was United States district attorney of Franklin County in 1847–1849 and in 1849 was elected as a Whig to the state assembly, but in 1856 he joined the ranks of the then newly-organized Republican party. He was a member of the New York assembly in 1858–1859; in 1860 was elected to Congress; in 1867 was president of the State Constitutional Convention; was re-elected to Congress 1869 and served until 1877, taking a prominent part in the adjustment of Southern affairs under the Reconstruction Act and settling the political difficulties in Louisiana by the well-known Wheeler Compromise. He was vice-president of the United States under Hayes in 1877–1881.

WHEELER, William Morton, American educator and zoologist: b. Milwaukee, Wisconsin, March 19, 1865; d. Cambridge, Massachusetts, April 19, 1937. His education began in his native city, where he remained a few years as curator of the public museum. After a fellowship in Clark University, Worcester, Mass., he received his doctor's degree there in 1892. He went abroad and studied in Würzburg and Liege universities in 1893, while an instructor in embryology in the University of Chicago, where he was made an assistant professor in 1897. He was professor of zoology in the University of Texas, 1899–1903; and curator of invertebrate zoology, American Museum of Natural History, 1903–1908. From 1908 he was professor of entomology in Harvard University. During his professorship at Harvard he was dean of the Bussey Institute for Research in Applied Biology for 14 years. He was also a research associate of the American Museum of Natural History and editor of several scientific journals. His books include *Ants, Their Structure, Development and Behavior* (1910); *Social Life Among the Insects* (1923); *Demons of the Dust, A Study in Insect Behavior* (1930).

WHEELING, city, West Virginia, Ohio County seat; altitude 687.07 feet; on the east bank of the navigable Ohio River; 61 miles southeast of Pittsburgh, Pa.; on the Baltimore and Ohio; the Pennsylvania; and the Wheeling and Lake Erie railroads. Its airport, dedicated in November 1946, is 11 miles north-northeast of the city. The city is served by bus and truck lines providing, with the railroads, a complete system of transportation to other cities in all directions. Third city of the state in population, Wheeling is a busy industrial center. Wheeling's numerous mills and factories turn out a varied list of products, with metals and glass leading. It has been said that the city's output runs through the industrial alphabet from A to Z, aluminum to zinc. The list includes stogies and packaged tobacco, chinaware, sausage, textile products, and mattresses. Wheeling's location on the Ohio made it a strategic point in the trade that accompanied development of the middle west. Important contributing factors to the city's growth were an abundance of coal gas in the vicinity, and its possession of early transportation facilities. Wheeling was fortunate in being on the line of the National Road, which reached it in 1818; and with the arrival of the Baltimore and Ohio Railroad in 1852 the city acquired increased importance as a terminal on the Ohio River. In the first half of the 19th century this river town, at the intersection of land and water transportation, handled a huge volume of commodities and goods. Development of this traffic led to a clash with Pittsburgh. The upstream city strove to prevent building of a bridge between Wheeling Island and the mainland on the West Virginia side, but was twice defeated in the courts. Steamers bound to and from Pittsburgh had thereafter to adjust their smokestacks to the clearance of the bridges. A suspension bridge was formally opened Nov. 15, 1849, and at that time was the longest suspension bridge in the world. Wheeling Island, more than a mile long, is part of the city, and is occupied by a residential section. "Wheeling Downs" is situated at the south end of the island and is one of the country's most beautiful half-mile race tracks.

Wheeling may be said to resemble Pittsburgh in its development of community culture upon a foundation of industrial life. The school systems, public and parochial, are excellent. Nearby West Liberty was chartered as an academy in 1837. It then became a normal school, and after a while, a teachers college. In 1943, the institution became West Liberty State College. Mount de Chantal Academy (1848) is under the control of the Sisters of the Visitation. Linsly Institute was founded in 1814 and now stands within a bend of Wheeling Creek, near the old National Road, now a federal highway. Oglebay Institute, in Oglebay Park, is operated

in connection with the Agricultural Extension Division of West Virginia University. The city library is well stocked; it has a collection of paintings that depict scenes from the city's history. The traveling "Bookmobile" makes 54 stops in the area on its circuit of schools and sections of the county and carries 2,500 volumes.

Wheeling has a number of parks and playgrounds. Of the parks the most notable is Oglebay, which lies beyond the city boundary but was bequeathed to the people of Wheeling by Earl W. Oglebay, in 1926, "for purposes of public recreation and education." In 1928 Wheeling accepted the princely bequest through formal action of the city council. It contains a golf course and swimming pool, playing fields, and camp sites; the Mansion House, equipped as a museum of history and the arts; and a museum of natural history. Concerts, lectures and plays are presented in a year-round program. There are in the city a number of musical organizations, of which one is a large symphony orchestra. Points of pride to the local folk and of interest to the visitor are the city-county building, once the state capitol; the sites of Fort Van Meter and Fort Henry, built in 1774 and defended against British and Indian attacks in 1777 and 1782. The last battle of the American Revolution in which British soldiers and Colonial militia participated took place at Fort Henry, Wheeling, Sept. 11, 1782. At Monument Place on Wheeling Creek, there is a mansion built by Moses Shepherd in 1789 on the site of old Fort Shepherd. Lafayette and Henry Clay both visited Monument Place and a statue was erected in honor of Henry Clay but was removed from the grounds due to the construction of a new bridge. It is now in the Mansion Museum at Oglebay. Other distinguished visitors were Calhoun and Andrew Jackson. In Wheeling Municipal Park is one of the "Madonna of the Trails" monuments.

First settlement of the city's site was in 1769; Col. Ebenezer Zane (q.v.) and his two brothers built a cabin in which one stayed while the others went back for their families and other settlers. In 1793 Colonel Zane platted a town; it was first called Zanesburg, and that was its designation when the seat of county government was transferred here from West Liberty. Incorporation as a town was effected in 1806, under the name of Wheeling. The city charter was granted in 1836. In 1861 Wheeling was declared capital of "the restored government of Virginia" by Virginians opposed to secession. West Virginia became a state in 1863, and from that year to 1870, and again from 1875 to 1885, Wheeling was its capital. Pop. (1940) 61,099; (1950)

WHEELOCK, hwē'lŏk, **Eleazar,** American clergyman and educator: b. Windham, Conn., April 22, 1711; d. Hanover, N. H., April 24, 1779. He was graduated at Yale in 1733, and from 1735 to 1770 was pastor of the Second Congregational Society in Lebanon, near Columbia, Conn. In 1754 he opened a missionary school for Indians, known from Joshua Moor, who gave for its use a building and two acres of ground, as Moor's Indian Charity School. This he removed in August 1770 to Dresden (now Hanover), N. H., founded Dartmouth College, to which a charter had been granted in 1769. He was president of Dartmouth from 1770 to 1779.

WHEELOCK, John, American educator: b. Lebanon, Conn., Jan. 28, 1754; d. Hanover, N. H., April 4, 1817. He was son of Eleazar Wheelock (q.v.). He entered Yale in 1767, but became a member of the new Dartmouth College at Hanover, N. H., and was graduated with the first class in 1771. In 1775 he was elected a member of the provincial assembly, in 1777 was appointed a major in the New York forces and soon after lieutenant colonel in the Continental army. In 1778 he led an expedition against the Indians. In 1779 he was elected president of Dartmouth College and remained there, except two years, until 1817. He bequeathed half his large estate to Princeton Theological Seminary. He published *Essay on the Beauties and Excellencies of Painting, Music and Poetry* (1774); *Sketches of the History of Dartmouth College* (1816).

WHEELWORK. See Clock.

WHEELWRIGHT, hwēl'rīt, **Edmund March,** American architect: b. Roxbury, Mass., March 14, 1854; d. Aug. 16, 1912. He was graduated at Harvard University in 1876 and later studied architecture at the Massachusetts Institute of Technology and in Europe. He was afterward connected with different architects in Boston, Albany and New York, and from 1883 conducted his own business in Boston. He was senior partner in the firms Wheelwright and Haven and Wheelwright, Haven and Hoyt. He was city architect of Boston in 1891–1895. He designed the Hartford Bridge, the Cambridge Bridge, the Boston Opera House, Jordan Hall at Boston, the Cleveland Museum of Art, and was one of the architects of the Boston Museum of Fine Arts. He wrote *Municipal Architecture in Boston,* 2 vols. (1898); *School Architecture* (1901).

WHEELWRIGHT, John, American Puritan clergyman: b. Lincolnshire, England, 1592?; d. Salisbury, N. H., Nov. 15, 1679. He was a graduate of Cambridge and vicar of Bilsby, near Alford, Lincolnshire; but in 1636, being driven from his church by Archbishop Laud, he emigrated to Boston, Mass., where the same year he was chosen pastor of a branch of the Boston church at Mount Wollaston, in what is now Quincy. The celebrated Anne Hutchinson (q.v.) was his sister-in-law, and he partook of her views. Differences of opinion led to personal animosities between him and John Wilson, the pastor of the Boston church; and the General Court appointed a fast in January 1637, partly to heal these dissensions. On this occasion Wheelwright preached in Boston and, as his enemies asserted, denounced the ministers and magistrates. The General Court pronounced him guilty of sedition and contempt, for which in November 1637 he was banished from the colony. In 1638 he formed a settlement on the banks of the Piscataqua, which he called Exeter. After a residence of five years here the town was declared to be within the limits of Massachusetts, and he removed with a part of his church to Wells in the district of Maine. In 1644 his sentence of banishment was revoked, in consequence of some acknowledgments on his part, and he returned to that colony in 1646 and settled in Hampton. In 1654 he published his *Vindication.* About 1657 he went to England, where Cromwell, who had been his college class-

mate, received him cordially; but he returned in 1660 and in 1662 settled as pastor in Salisbury, N. H. His *Writings,* with a memoir, edited by C. H. Bell, were published by the Prince Society in 1876.

WHEELWRIGHT, William, American pioneer promoter of steam navigation, railways and telegraphy in South America: b. Newburyport, Mass., Mar. 16, 1798; d. England, Sept. 26, 1873. A descendant of John Wheelwright (q.v.), he attended Phillips Academy, Andover, and at 16 shipped as a cabin boy to the West Indies. Three years later he commanded a Newburyport bark sailing to Rio de Janeiro. In 1823, master of the *Rising Star,* Newburyport to Buenos Aires, he ran her aground in the Rio de la Plata. From 1824 for five years he was United States consul at Guayaquil, Ecuador, and there established a prosperous business. He then moved to Valparaiso, Chile, where he did much to develop that city, constructing a lighthouse and other port facilities, also gas and water works. By 1838 he had obtained concessions from South American west coast countries for a steamship line, and in 1840 he secured British financial backing and a charter for the Pacific Steam Navigation Company, which inaugurated regular service between Valparaiso and Callao, later extended to Panama. Between 1849 and 1852 he built the first railway in South America, connecting the Chilean port of Caldera with the rich copper and silver mines at Copiapó, and in 1850 the first telegraph line. Starting in 1855 from Rosario, Argentina, he began construction of the first transcontinental railroad, a project encouraged by Presidents Mitre and Sarmiento, and financed by the English railway magnate Thomas Brassey. The Grand Central Argentine Railway was opened in 1870 as far as Córdoba, but its trans-Andean portion was not completed until 1910. His last notable achievement was the creation of the port of La Plata, Argentina, near where he had been wrecked a half century earlier; the rail link connecting Ensenader with Buenos Aires was completed in 1872. Valparaiso commemorated him with a bronze statue in 1876. His strict integrity, bluff but kindly manners, and generous nature earned him general esteem. He left part of his large fortune as a fund for the technical education of Protestant youths of his birthplace.

WHELK, whĕlk, a gastropod mollusk of the genus *Buccinum* and order Ctenobranchiata. The large or common whelk (*B. undatum*) is of common occurrence on both sides of the north Atlantic, and is distinguished by the shell having its canal notched, and the mouth or aperture of large size. The whorls of the shell, which has a thick horny epidermis, are few and rounded. The red whelk, or "roaring buckie" of the Scotch (*Fusus antiguus*), belongs to the family Fusidae (q.v.). The tulip whelk (*Fasciolaria tulipa*) is very richly colored and inhabits the tropical seas. The purple whelk (*Purpura lapillus*) is so named from its affording a part of the dye which made Tyre of old famous. The whelk is used for food in Europe, especially in the south of England where the chief fisheries are at the mouth of the river Thames.

WHEN LILACS LAST IN THE DOOR-YARD BLOOMED. Swinburne called this elegy on Abraham Lincoln by Walt Whitman "the most sonorous anthem ever chanted in the church of the world." Such praise may be too high for the poem, but it can hardly be denied a place among the great elegies of the English language. The highly artistic and carefully wrought structure of the poem somewhat corresponds to that of a symphony, in its varied and intricate harmonies, and its three leading motifs of the lilacs, the evening star and the song of the thrush, which, constantly recurring, finally merge into the poet's song of love, regret and consolation. As in much of Whitman's best work, nature is here not a mere background, but is suffused with human feeling and becomes one with it. The scenes before the house in the dusk and in the swamp with the thrush, the vast panorama of country and town which loved Lincoln and which now laments him—these are not mere pictures, but realities; are not apart from the human passions of the poem, but an essential ingredient of them. The free verse, with its irregular rhythms and its lines of varying length, permits an immense range of emotional effects, of exquisite melodies and vast harmonies, perhaps not attained by any other poem in American literature; and Whitman's characteristic magic of phrase weaves its spell in such lines as "the yellow gold of the gorgeous, indolent, sinking sun," and "the huge and thoughtful night." The elegy gives no such intellectual estimate of Lincoln as Lowell attempts in the *Commemoration Ode;* it is simply a song—a lament and a consolation. Its emotion appears as spontaneous and unstudied as it is sincere and unrestrained; but for all that the poem is none the less a nobly planned and carefully executed work of art.

MARION TUCKER.

WHERRY, William Macky, American soldier: b. St. Louis, Mo., Sept. 13, 1836; d. Nov. 3, 1918. He was educated at the University of Missouri and studied law. Serving through the Civil War, he was present at the surrender of Gen. J. E. Johnson. Brevetted brigadier general of volunteers in 1865, he was mustered out of the volunteer service in 1866, and appointed captain in the regular army. Subsequently he served on frontier duty. In the war with Spain in 1898 he took part in the battle of San Juan Hill and in the capture of Santiago. Promoted brigadier general on Jan. 7, 1899, he was retired the same month.

WHETSTONE, whĕt'stōn, any stone used for sharpening tools. Sandstones and fine mica schists form the coarser kinds. Silicious clay rocks and particularly the fine compact rocks made of quartz-mud, such as the Arkansas stone or novaculyte, form the more desirable varieties for oilstones and delicate hones.

WHEWELL, hū'ĕl, **William,** English scholar: b. Lancaster, May 24, 1794; d. Cambridge, Eng., March 6, 1866. He was graduated from Trinity College, Cambridge, in 1816, and in due course became a fellow and tutor of his college. From 1828 till 1832 Whewell was professor of mineralogy, and in 1838 was elected to the Knightbridge chair of moral philosophy, which he held till 1855. In 1841 he became master of Trinity and in this position labored earnestly and successfully to obtain for the natural and

moral sciences a better recognized position among the studies of the university. He became Fellow of the Royal Society in 1820, and was one of the first members of the British Association, of which he was president in 1841. Whewell was a strong, healthy, clear-headed man, possessed of a vigorous and capacious intellect, and endowed with extraordinary powers of acquiring and retaining knowledge. The extent and variety of his attainments were very unusual. Yet there was nothing superficial about his learning, notwithstanding the well-known *mot* of Sydney Smith, that "science was his forte and omniscience his foible." Besides other gifts, he built at his own expense, and presented to his college, a *hostel*, or collection of chambers for undergraduates. His principal writings include the Bridgewater treatise 'Astronomy and General Physics, considered with reference to Natural Theology' (1833); 'History of the Inductive Sciences' (1837); 'Philosophy of the Inductive Sciences' (1840); 'Novum Organum Renovatum'; 'Indications of the Creator'; 'History of Scientific Ideas'; 'Elements of Morality, including Polity'; 'Lectures on Systematic Morality'; 'Architectural Notes on German Churches'; 'On Liberal Education in General'; 'Lectures on the History of Moral Philosophy in England'; 'Philosophy of Discovery'; 'History of Moral Philosophy'; 'Platonic Dialogues for English Readers.' He was the author of the well-known anonymous essay, 'The Plurality of Worlds.' Consult Todhunter, 'Whewell: an Account of His Writings' (1876); 'Life,' by Mrs. Stair Douglas (1881); Clark, 'Old Friends at Cambridge and Elsewhere' (1900).

WHEY, a clear, straw-colored liquid, consisting of the part of milk which remains fluid after the milk has been curdled by the use of rennet in cheese making, or by the action of the acid in the natural souring of the milk. Its average percentage of solids is 6.96, of which .36 per cent is fat, .84 per cent proteins and 5.76 per cent chiefly sugar, with a trace of salts and other matter. Over eight billion pounds of whey are produced in the United States annually by the manufacturers of cheese and casein, and until recent years milk sugar was practically the only product made from it. Lately lactofflavin, of which whey is an excellent source, has become of great interest to feed manufacturers, some of whom sell feeds on the basis of lactofflavin content. Whey is also a practical starting material for the production of lactic acid, by a process that converts the milk sugar, nearly pound for pound, into this acid. However, by far the greater part of the whey produced in the country still runs to waste or is fed to animals.

WHIGS, a word of British origin, used for many years to designate members of an American political party. It had previously been used in America in colonial and Revolutionary times to indicate those who were opposed to the attempts of the British Crown to deprive the Americans of their political and commercial rights. It disappeared with the close of the Revolution, and did not appear again until the National Republicans, successors to the Federalists (q.v.), adopted the name of Whigs. Those Whigs who considered the slavery question settled by the compromise of 1850 were called in Massachusetts "Cotton Whigs," and in New York "Silver Grays." The Whigs continued to exist as one of the two great parties until the election of 1852, which was followed by a division on the slavery issue, the anti-slavery Whigs joining the Republican party, and the others making common cause with the Democracy.

The term was prominent in British political history for nearly two centuries to designate the political party which advocates such changes in the Constitution as tend in the direction of democracy. Defoe thus accounts for the origin of the name: "The use of it began then when the western men (the peasantry of the West Lowlands of Scotland), called Cameronians, took arms frequently for their religion. Whig is a word used in those parts for a liquor (*whig*, Scotch for *whey*), which the men used to drink . . . and so became common to the people who drank it. It afterward became a denomination of the poor harassed people of that part of the country, who, being unmercifully persecuted by the government, against all law and justice, thought they had a civil right to their religious liberties, and therefore resisted the power of the prince (Charles II)." Monmouth was sent to quell the insurrection, and "at his return he found himself ill-treated for having used the rebels too mercifully; and Lauderdale told Charles, with an oath, that the duke had been so civil to the Whigs because he was a Whig himself in his heart. This made it a court word, and in a little time the friends and followers of the duke began to be called Whigs."

A different origin is, however, assigned to the term. Sir James Balfour, in writing of an outbreak which occurred in 1648, in his own day, calls the enthusiasts "whigamores," and Burnet, who was then five years old, offers the following explanation: "The southwest counties of Scotland have seldom corn enough to serve them throughout the year, and the northern parts producing more than they need, those in the west come in the summer to buy at Leith the stores that come from the north; and from a word, whiggam, used in driving their horses, all that drove were called the whigamores, and shorter, the whiggs. After the news came of Duke Hamilton's defeat (in 1648), the ministers animated their people to rise and march to Edinburgh; and they came up, marching at the head of their parishes, with an unheard-of fury, preaching and praying as they came, . . . This was called the whigamores inroad, and ever after that, all that opposed the court came in derision to be called whigs; and from Scotland the word passed to England." The Whigs brought about the Revolution of 1688–89, and established the Protestant succession; they were chiefly instrumental in obtaining the abolition of the slave-trade and slavery, the repeal of the Test and Corporation Acts, Catholic emancipation, Parliamentary and municipal reform, the repeal of the corn-laws and similar measures. The term Liberals is now generally applied to the representatives of this party; the extreme section of the party, who agitate for sweeping innovations, usually have a more or less close connection with the Whigs, and have

adopted the name of Radicals. See also UNITED STATES—41. *Sectional Conflict and Preservation of the Union, 1815–1877.*

WHIN. See FURZE.

WHIN, hwĭn′, **WHINSTONE,** a mining term for intruded igneous or basaltic rock generally of a firm texture and resistant character. The great Whin Sill of Northumberland is a typical example.

WHINCHAT, hwĭn′chăt, a European warbler (*Saxicola rubetra*), allied to the stonechat, receives its name from its frequenting whin and furze bushes. It is also called furzechat. It possesses a long white streak, passing across the sides of the head, which, with the upper parts of the body, is colored brown. The lower part is yellowish. Its length is usually under 10 inches; it lays four to six green-blue eggs in ground nests. Its song is very sweet, and sometimes imitative. Its range is Europe, Africa, and occasionally western Asia.

WHIP SNAKE, a light brown harmless snake (*Philodryas viridissimus*) with whitish tail, closely related to the black snake. It is called also coach-whip. It is found in the southern United States, and Mexico, and is especially abundant in Texas. Its name is given it because of its general appearance. A group of very slender poisonous African and Asiatic tree snakes, the Dipsadinae, are called whip snakes. Of the subfamily, Elapidae, they are leaf-green in color, which helps to conceal them from their prey.

WHIPPING POST, a post at which punishment was inflicted by the law of England, and still exists in the State of Delaware, chiefly for minor offenses. The criminal law in England enumerates several offenses for which whipping at the post may be inflicted on males under 16. A subsequent act enacts that when the offender is under 14 the number of strokes is not to exceed 12. In Scotland no person above 16 is to be whipped for theft or crime committed against person or property. In connection with the pillory (q.v.) it flourished in America in colonial times.

WHIPPLE, hwĭp″l, **Abraham,** American naval officer: b. Providence, R. I., Sept. 26, 1733; d. near Marietta, Ohio, May 27, 1819. In the French and Indian War he commanded the privateer, *Game Cock,* and on one cruise captured 23 prizes. He had charge of the expedition which on June 8-9, 1772 destroyed the British armed cruiser, *Gaspée.* He commanded successively the *Columbus,* the *Providence,* a schooner, and its namesake, a frigate, and from 1775–1779 with the schooner, *Providence,* took more prizes and destroyed more vessels than any other commander in the colonial service. With the frigate *Providence* he evaded British surveillance and succeeded in getting to sea with important dispatches for France, and in 1779 performed the daring exploit of capturing 10 vessels from a merchant fleet of nearly 150 sail, eight of which reached Boston safely, and brought about $1,000,000 when sold. He commanded the naval forces at Charleston, S. C., in 1780, but was captured and held a prisoner until the close of the war. He commanded the vessel which in 1784 unfurled the first American flag on the river Thames.

WHIPPLE, Edwin Percy, American author and critic: b. Gloucester, Mass., March 8, 1819; d. Boston, June 16, 1886. He began writing for newspapers in 1837, became superintendent of the Merchants' Exchange reading room, 1837–1860. He first attracted attention by his critical panegyric on Thomas Babington Macaulay in the Boston *Miscellany* (1843), and in October of that year entered upon his career as lecturer, chiefly on literary topics. He contributed much to reviews and journals, and published *Essays and Reviews,* 2 vols. (1848–1849). These included discussions of *English Poets of the Nineteenth Century,* as well as of *Byron Rufus Choate,* and *Henry Fielding.* He was literary editor of the Boston *Globe* 1872–1873. The greater part of his work is composed of essays on literature and authors, though he treated other subjects with an almost equal discrimination. His *Literature of the Age of Elizabeth* (1876) probably shows him to best advantage, though his estimates of the moderns are also painstaking and for the most part just. His characterizations were penetrative, and at times very effectively expressed. He lacked, however, to a large extent, originality and power, and Whittier's declaration that "with the possible exception of Lowell and Matthew Arnold, he was the ablest critical essayist of his time" cannot now be accepted. Among his further publications are *Literature and Life* (1849), a small volume of lectures; *Character and Characteristic Men* (1866); *Success and its Conditions* (1871). Three books appeared posthumously, *Recollections of Eminent Men, with Other Papers* (1887), with an introduction by C. A. Bartol; *American Literature and Other Papers* (1887), with a brief introduction by Whittier, and containing the centennial review of American literature written in 1876 for *Harper's Magazine;* and *Outlooks on Society, Literature and Politics* (1888).

WHIPPLE, George Hoyt, American pathologist: b. Ashland, N. H., Aug. 28, 1878. He received his A.B. at Yale 1900; his M.D. at Johns Hopkins 1905. He was on the faculty of Johns Hopkins from 1905 until 1914, first as assistant in pathology, later instructor, resident pathologist, and associate professor. He went to the Panama Canal Zone in 1905 for a year as pathologist at Ancon Hospital. He was professor of research medicine at the University of California from 1914 to 1921, and from 1921 until his resignation in 1952 he was dean and professor of pathology, School of Medicine and Dentistry, at Rochester University, New York.

His researches have covered a wide field in internal medicine. His best known work deals with anemia, though he has written over 200 articles on diverse medical subjects. He was awarded the Nobel Prize for medicine, 1934, and has received many honorary degrees, and medals. He was president of the American Association of Pathologists, 1939.

WHIPPLE, Henry Benjamin, American Protestant Episcopal bishop: b. Adams, Jefferson County, N. Y., Feb. 15, 1822; d. Faribault, Minn., Sept. 16, 1901. Ill health prevented his entering college, for which he had prepared, and he engaged in business for several years. In 1847 he began a theological course privately, took priest's orders in the Episcopal Church, in 1850 and was rector of Zion Church, Rome, N. Y., 1850–1857 and of the Church of the Holy

Communion, Chicago, 1857–1859. In October 1859 he was consecrated first bishop of Minnesota. He very soon afterward organized the Seabury Mission at Faribault, out of which have since been developed the Cathedral of Our Merciful Saviour, Seabury Divinity School, the Shattuck School for boys, and Saint Mary's Hall, a school for girls. Bishop Whipple was widely known as the apostle to the Indians on account of his labors among them both for their material as well as spiritual welfare. By the Indians he was called "Straight Tongue." He thoroughly understood the Indian character and at the time of the Sioux Massacre in 1862 insisted that the trouble came directly from the false dealing of the whites with the Indians. In 1876 he secured the Sioux treaty, opening up the best portions of Dakota to white settlement, and his advice in regard to Indian affairs was sought by every President from Lincoln to McKinley. In his *Lights and Shadows of a Long Episcopate* (1899) the character of the Indian problem will be found very fully treated. Bishop Whipple traveled extensively and was well known and highly regarded in England, while in his own country he was beloved and respected by men of every creed.

WHIPPLE, Squire, American civil engineer: b. Hardwick, Mass., March 24, 1804; d. Albany, N. Y., March 15, 1888. He was graduated from Union College in 1830 and engaged in canal and railway surveying. He patented in 1840 an iron bridge truss of the bowstring type, several of which were built over the Erie Canal. After 1852 he built several bridges known as the Whipple truss, and in 1872 took out a patent for a lift drawbridge, one of which was built over the Erie Canal at Utica. He wrote *The Way to Happiness* (1847); *Treatise on Bridge Building* (1847); and *The Doctrine of Central Forces* (1866).

WHIPPLE, William, American soldier and politician: b. Kittery, Me., Jan. 14, 1730; d. Portsmouth, N. H., Nov. 28, 1785. Before 1751 he was captain of a merchantman trading with the West Indies and making voyages to Africa for slaves. But in 1760 he set up as a merchant at Portsmouth, and in 1775 was chosen a delegate to the New Hampshire provincial congress. He was also made a member of the provincial council of safety. In January 1776 he was elected to the Continental Congress, continuing to hold his seat until September 1779, and signing the Declaration of Independence. As brigadier general of New Hampshire troops, he commanded a brigade in the operations against Burgoyne in 1777, and assisted in negotiating the terms of the surrender of the British general. Commanding the New Hampshire forces, he cooperated with Sullivan in the campaign against the British in Rhode Island in 1778. From 1782 to 1784 he was superintendent of finance for New Hampshire, and from 1782 until his death a judge of the Superior Court. He was president of the commission for the adjustment of the dispute between Connecticut and Pennsylvania regarding the Wyoming Valley region.

WHIPPOORWILL, hwĭp-pŏŏr-wĭl′, a North American nightjar (*Antrostomus vociferus*). In this genus the rictal bristles are greatly developed and reach far beyond the tip of the small, weak bill, and sometimes they are fringed. The nostrils are not tubular as in *Nyctidromus*. The whippoorwill is ordinarily 10 inches long with a spread of wings of about 18 inches, the mouth bristles are simple, the tail long and rounded, and the soft lax plumage closely and delicately mottled with gray, black, white and yellowish brown, the female with the tips of the outer tail-feathers tawny, the same parts in the male white. These birds inhabit the United States and Canadian provinces east of the plains, and breed chiefly northward, throughout most of this area. Being migratory, they reach the Middle and New England States in May. The whippoorwills are strictly nocturnal, but usually become quiet by midnight, except on moonlight nights when they continue active till dawn; but at all times they are most vociferous during the early evening. The song is a clear, energetic whistle, aptly syllabified in the name, strongly accented on the last syllable, and is repeated many times; then, after a short pause begins anew. They fly noiselessly in pursuit of flying insects, skimming low over stone walls and bushes, or even alighting on the ground to pick up an insect. Large moths, nightflying beetles and insects frequenting forest borders are their chief food. When they pass close to a person at night they may be heard to utter a low murmuring sound. Unlike the great majority of birds they always perch along and not across a bough, a peculiarity which they share with other weak-footed birds. Whippoorwills do not fly abroad during cloudy days like the night hawk, and as a consequence their appearance is unknown to many persons to whom the song is quite familiar. No nest is made, and the two elliptical, creamy white eggs, marked with brown and lavender, are laid in a depression on the bare ground, or a log. When danger threatens the old birds often carry the eggs or young in their mouths to a place of safety. A much larger species of similar colors and habits, but more southern in its range, is the chuck-will's-widow (*A. carolinensis*) (q.v.). In this species the rictal bristles are provided with lateral filaments.

WHIPTAILED SCORPION. See SCORPION.

WHIRLIGIG BEETLE. See WATER-BEETLES.

WHIRLPOOL, a circular eddy or whirling current in a stream or the sea, of considerable dimensions, produced by the configuration of the channel, by meeting currents, by winds meeting tides, etc. There are some very celebrated whirlpools, such as Charybdis, in the strait between Sicily and Italy; and the Malström, off the coast of Norway. When the agitation is increased by high tides or winds they sometimes become dangerous to navigators. But large modern vessels cannot be sucked into any whirlpool, like some of the small craft of the ancients.

WHIRLWIND. See CYCLONE; WATERSPOUT.

WHISKEY or **WHISKY,** the name applied to a well-known liquor distilled from corn, bar-

ley, wheat, oats and other grains; potatoes, beet and other roots and sometimes molasses and subsequently refined, colored and flavored by various processes. However under regulations under the Federal Food and Drug Act the name whiskey alone is limited to grain distillates. Whiskey from malt alone is made in the Scotch distilleries as follows: The malt is bruised upon cylinders and the quantity intended to be mashed is put into the mash pan, water at a temperature of about 170°F. being then added. After two or three hours' agitation the whole is left to repose for an hour and a half, and then the worts are drawn off to about one-third of the water employed. About two-thirds of the first quantity of water of a somewhat higher temperature is put into the pan, and the agitation is renewed for about half an hour. After a second period of repose these second worts are drawn off. Both infusions are now cooled down as quickly as possible to the temperature of 80° or 70° to prevent souring; the wort is cooled down by being exposed in shallow coolers to currents of air, or by being passed through serpentine tubes surounded with cold water. More water may be let into the pan, and a third wort drawn off, which may be fixed with the other worts, or used instead of water for the first infusion of malt. The quantity of saccharine matter converted into alcohol depends upon the proportion of ferment or yeast introduced into the worts; if too little be used, a portion of the sugar will remain undecomposed; if too much, the spirits will have an unpleasant taste. Generally the worts are let down at the specific gravity of 1.050 or 1.060, and at a temperature of 60° to 50°. For every 100 gallons a gallon of good porter yeast is added and thoroughly incorporated by agitation. An hour after the addition of the yeast fermentation begins to show itself by a ring of froth around the edges of the vat, and in about five hours frothy bubbles cover its whole surface. Large vats generally afford a better result than small ones, owing to the equality of the fermenting process. It is considered good worts when the specific gravity comes down to that of water and superior worts when it falls to 0.995. In about 48 to 60 hours the wash begins to get clear and comparatively tranquil, and is then ready for distillation. In its simplest form the still consists of a copper boiler into which the wash is poured. This vessel is furnished with a close head terminating in a bent tube which passes in a spiral form through a vessel filled with cold water. (See DISTILLATION.) On the application of heat to the still the spirit begins to rise in vapor at 175°, along with more or less steam. These vapors are condensed in passing through the spiral tube, and trickle in fluid form into a receiver. The product of this first distillation is called low wines. This is again distilled at a lower temperature, which gets rid of part of the water and of the fetid oils that had come over with the alcohol. Great purity and strength can only be obtained by repeated distillation. The casks or packages into which these spirits go are not charred, as in the United States, but preference is given to empty wine or rum casks which impart both flavor and color, and when plain casks are used, flavoring and coloring is accomplished by means of blending wines. If nothing whatever is added to the spirits which are put in plain casks, the coloring and flavoring is attributable to the tannic acid extracted from the wood, and the oxidation of the aldehydes in combination with the ethyl alcohol.

Before prohibition in the United States, Kentucky, Maryland and Pennsylvania whiskies constituted the majority of those consumed for drinking purposes, either medicinal or otherwise. Kentucky whiskies were known as Sour Mash, Sweet Mash and Bourbons, and Pennsylvania and Maryland whiskies as Eastern Ryes. At the head of the various processes of distillation, for excellence of quality of the spirit produced thereby, stood that known as fire copper, which was the method that originally established the high reputation of whiskey in these states; those later employed, while giving a larger yield of spirit to the bushel of grain, procured it at the expense of the quality and flavor thereof. In this process the corn and rye meals were scalded or mashed, with hot spent beer, which was the liquid residue of the previous distillation. The mash was then allowed to cool to the proper temperature, when malt was added, and the mash, diluted with a sufficient quantity of water, was left to ferment the time established by law. The diluted mash when fermented was called beer. The beer was distilled in three different ways. In the very smallest distilleries, it was sometimes boiled in copper stills, over wood fires; the vapor, passing through a copper coil or worm, immersed in cold water, was condensed and delivered into a receiver. The condensed liquid was called low wines or singlings. Singlings contained only a small amount of spirit. This manner of boiling the beer was seldom used, as the large quantity of grain contained in the beer made it apt to cake in the still; and, becoming scorched, it gave the whiskey a strong, smoky flavor, a very little of which, however, was not considered objectionable. The singlings were doubled or again distilled in small copper stills, or doublers, over wood fires, and the vapor again condensed in a copper worm, whence it was delivered into the receiving cistern. Another name for doublings is high wines. The usual way of distilling sour mash whiskey was to boil the beer in a wooden still by admitting steam, the vapor being condensed into singlings; the singlings were doubled as above. In the third way the beer was boiled in a copper still by steam confined in a copper pipe placed inside the still. The singlings were doubled in small copper stills, over wood fires, in the same manner described. This latter way was considered a great improvement, as it avoided both the scorching of the grain in distilling the beer and the admission of live steam, while it preserved all the characteristics so highly prized in sour-mash, fire copper whiskies. The yield by the sour-mash process was from two to three gallons to the bushel of grain.

Most whiskey was made by the process known as steam. In this the corn and rye meals and malt were mixed with water in the mash-tub, where they were scalded with direct or live steam, introduced by means of a perforated pipe at the bottom of the tub. When fully scalded the mash was cooled down and run into the fermenting tubs. Fresh yeast was used in fermenting, which gave the name of sweet mash. The still was made of wood and divided into two or three compartments. When the still was charged a certain amount of beer was placed in each compartment, live steam was admitted into the lower, which boiled the beer, and the vapor from it

ascended through a curved pipe into the compartment above, where its continued reception boiled the charge therein contained; the vapor from this again ascended into the next compartment above, where the same process was repeated. The vapor then passed through a pipe into a wooden doubler, where it boiled the low wines; and the vapor arising thence passed into a copper worm, where it was condensed and then run into the whiskey cistern. Only one worm was used and one condensation made. High wines, as well as whiskey, was manufactured by this process. The yield was from three and a half to four and a half gallons. In making whiskey by the steam copper process, the mash was made and fermented and the beer boiled in the same manner as for the steam process. The same wooden still was used; but, instead of the vapor from the upper compartment passing directly into a wooden doubler, it was run through a worm and condensed into singlings, which was doubled in a copper still by live steam, or by steam confined in a jacket around the still, or sometimes by fire underneath.

In locating a distillery a full supply of clear, bright water that contains the proper chemical qualities is the first consideration. It is well known to both chemists and practical distillers that water containing a large quantity of sulphate of lime, earthy carbonates and no organic matter is best adapted to distilling. The lime and carbonates being dissolved in the acid generated during the fermentation of the mash mostly pass off in the form of carbonic acid gas and leave the water soft and best suited for extracting the active properties of the malt and grain. Great care has to be taken in the selection of the grain to have it well developed and sound. Musty or unsound grain is fatal to the production of fine whiskey, and its defects become more prominent as the whiskey increases in age. Those distillers most careful to manufacture only fine goods use the grain that is grown in their own section of the country in order to have both the grain and water spring from the same kind of soil. Successful fermentation requires of the distiller not only constant attention, but also extensive knowledge both of the principles of chemistry and of practical results. It is exceedingly injurious to allow the fermentation to be prematurely concluded or to proceed too long. As a general rule, the slower the fermentation and lower the heat at which the distillation is carried on, the finer and purer will be the spirit. The mash being made and fermented, and the beer distilled by whatever process, the whiskey is collected in the cistern and thence run into barrels, under the control of the United States inspector, and in the custody of the United States storekeeper, who has also charge of it while in the bonded warehouse, till the tax is paid. Barrels, and the cooperage thereof, require much attention, and must be made of well-seasoned oak. For high wines they are not charred, but for whiskey they should be well charred, as the char has some peculiar chemical effect on the character and ripening of the whiskey that is very desirable.

The subsequent purity of the product depends largely upon the care exercised by the distiller in stopping the distillation when the temperature of the vapor rises above the boiling point of ethyl alcohol and water and certain flavoring bodies depending upon the material employed.

The process of fermentation which precedes that of distillation produces a number of alcohols radically different from ethyl alcohol (which, with water, is the body of whiskies) and which seriously serve to contaminate the product. These are usually referred to by the American distiller as the "heads" and "tails," because the former have a lower boiling point than that of ethyl alcohol, and the latter a higher boiling point, as a result of which a careful distiller can separate them from the main body of the distillate which is to be perserved.

In England these heads and tails are called "feints." Among these is fusel oil, from which it is very desirable that the spirit should be freed as much as possible. This may be partially accomplished by the action of charcoal and heat, which are the principles underlying the barrel-charring process, of refining and maturation. If, however, the fusel oil contents are too large to start with, they will never be sufficiently reduced by such process to make the product wholesome and palatable. In such case, they can only be removed or reduced by a subsequent process of rectification, including redistilling and the passage of the spirits through leach tubs. It follows, therefore, from the process of manufacture, that the fusel oil contents or percentage of impurities is not fixed or constant, and this fact led to the process called blending. Under the present system of Internal Revenue Laws in the United States, distilled spirits can be sold only by one who qualifies thereunder as a wholesale liquor dealer, and such person may also be a rectifier. A rectifier is one who rectifies, purifies or refines distilled spirits, or who merely mixes without refining. Whenever it is found that whiskey which has been subjected to the barrel-charring process still contains an excessive quantity of fusel oil, or has acquired an excessive quantity of tannic acid, it can only be corrected by redistillation or other rectifying processes or by the addition thereto of ethyl alcohol and water (termed for commercial purposes either neutral spirits or cologne spirits) which contains no fusel oil and no tannic acid. One effect of charring a barrel is to produce a coating of a gummy, resinous substance beneath the char and next to the hard wood which is classed as caramel and which not only imparts a flavor, but produces about two-thirds of the color usually obtained by spirits which have been stored in such a barrel for a length of time. The other one-third of the color is imparted by the tannin or flavescin which the spirits extract from the wood.

Since neutral spirits are seldom put in charred barrels, they retain their original color, which is water white, and when they are mixed with the whiskey which has been colored, this necessarily lightens the color, which has to be restored by the addition of plain caramel. Harmless flavorings are sometimes added to modify or soften the effect of the tannin, which is a severe astringent. On account of their diminished toxicity; smoothness, which sometimes results from the addition of sugar; and improved flavor, which results from diluting or diminishing the tannic acid, acetic acid and fusel oil, blends are considered by some more desirable than a simple whiskey.

The bulk of the so-called straight or simple American whiskies were made by adding water

to the high wines or doublings in the receiving cistern until they were reduced to 100 proof, or proof—approximately half ethyl alcohol and half water—and then storing them in charred barrels.

High wines contain higher alcohols known as impurities, created during the process of fermentation. If these impurities are removed from the high wines, the spirit is then termed neutral, but that term is properly applied to it only so long as it is kept in its original condition, free from any coloring or flavoring matters. To insure this result, neutral spirits are stored in paraffined or waxed barrels. Neutral spirits when put into charred barrels are converted into whiskey, but are milder in flavor and less fiery than whiskey produced from high wines.

Whiskey ranges from 70 to 120 proof, but all spirits that have been subjected to the process usually recognized as producing whiskey are considered whiskey without reference to their proof, though regulations under the Food and Drugs Act required the proof to be between 80 and 110 if the actual proof is not stated.

Other than the above no standard for whiskey was created by the federal laws, but many of the states adopted the standard which was originally laid down in the United States *Pharmacopeia,* which required that whiskey for medicinal purposes should be approximately from 88 to 110 proof, should contain no more than traces of fusel oil from grain and oak tannin from casks, a stated limit of free acid, and show a residue from 100 cc. evaporated on a water bath and dried at 212°F., of not more than 0.5 gr. Blended whiskies more nearly meet these requirements than straight whiskies.

Whiskey, whether called straight or blended, is composed of approximately half water and half ethyl alcohol, plus a color and a flavor, and the only substantial difference between the two consists in the percentage of fusel oil and tannic acid, which exists in straight whiskies in a larger amount than in blended whiskies.

Prior to the adoption of the 18th (Prohibition) Amendment to the Constitution, which became effective Jan. 16, 1920, the greatest amount of whiskey distilled in the United States in any one year was 100,647,000 gallons in 1911. On Feb. 20, 1933, Congress passed a joint resolution submitting to the states a proposed amendment to the Constitution repealing the 18th Amendment. This proposed amendment was approved by the necessary 36 states on Dec. 5, 1933, and became immediately effective.

WHISKEY FRAUDS, The, in American civil history, a national internal revenue scandal, which reached its climax in 1874 through the efforts of Secretary of the Treasury D. H. Bristow. Statistics showed that for some years prior to 1874 the United States had, in Saint Louis alone, lost at least $1,200,000 of revenue which it should have received from whiskey, yet special agents of the treasury set to work from time to time had failed to do more than cause an occasional flurry among the thieves. The Whiskey Ring was organized in St. Louis when the Liberal Republicans there achieved their first success. It occurred to certain politicians to have revenue officers raise a campaign fund among the distillers. This idea the officers modified later, raising money in the same way for themselves, and in return conniving at the grossest thievery. As it became necessary to hide the frauds, newspapers and higher officials were hushed, till the ring assumed national dimensions. Its headquarters were at St. Louis, but it had branches at Milwaukee, Chicago, Peoria, Cincinnati, and New Orleans, and an agent at Washington, D.C. A huge corruption fund was distributed among gaugers, storekeepers, collectors, and other officials, acording to a fixed schedule of prices. As a result of the investigation by Secretary Bristow arrests were made in nearly every leading city. Indictments were found against 152 liquor men and other private parties, and against 86 government officials, notably the chief clerk in the Treasury Department, and General Grant's private secretary, Gen. O. E. Babcock.

WHISKEY REBELLION, a popular name given to a local outbreak in opposition to the excise laws passed by Congress March 3, 1791. General objections were urged against the measure, and in western Pennsylvania the inhabitants considered the tax an unfair discrimination against their particular region and raised an insurrection. It became necessary for President Washington to call out an army of 15,000 militia to subdue the rebels, who dispersed without bloodshed.

WHISKEY RING. See Whiskey Frauds, The.

WHISPERING GALLERY, a gallery or dome of an elliptical or circular form, of peculiar acoustic qualities, arranged to echo faint sounds between certain points, the sounds being conveyed around the interior wall so that they may be readily heard, while the same are inaudible elsewhere in the interior. Thus, in an elliptical chamber, if a person standing in one of the foci speaks in a whisper, he will be heard distinctly by a person standing in the other focus, though the same sound would not be audible at the same distance under any other circumstances, or at any other place in the chamber. There is a whispering gallery in the Capitol at Washington, one at Saint Paul's Cathedral, London, and another at Gloucester Cathedral, England.

WHIST, a well-known game at cards, first clearly described by Edmond Hoyle (q.v.) in his *Short Treatise on the Game of Whist* (1743). See Bridge.

WHISTLE, a sharp, shrill, musical sound; also the instrument used to produce such a sound. An example is the policeman's whistle. A steam whistle is a sounding device connected with a steam boiler or other source of supply. It was first invented in 1826 by Adrian Stephens of Plymouth, to render audible the escape of steam from a safety valve. In one form it consists of a plate with thin edges for deflecting steam through an annular opening against the beveled rim of a hemispherical or elongated brass cup or bell.

WHISTLER, hwĭs'lẽr, **James Abbott McNeill,** American painter and etcher: b. Lowell, Mass., July 10, 1834; d. London, England, July 17, 1903. He received his first art lessons in

Russia, where his father was engaged from 1843 as an engineer supervising the construction of a railroad between St. Petersburg (now Leningrad) and Moscow. Upon his father's death in 1849, the family returned to the United States, and two years later young Whistler was appointed to the United States Military Academy at West Point. Discharged from the academy because of a failure in chemistry in 1854, he joined the United States Coast Survey as a draftsman but left this employment in the following year in order to study painting in Paris. He never returned to the United States. From 1855 to 1857 he was a pupil in the studio of Charles Gabriel Gleyre, an artist of the school of Jean Auguste Dominique Ingres. Thereafter, Whistler maintained studios alternately in Paris and in London.

Whistler's first set of etchings, known as the *Little French Series,* was published in Paris in 1858, but few copies were printed. It consists of 12 plates of figures, street scenes, and interiors. The second set, the *Thames Series* (1860), consists of 16 etchings of river scenes executed while the artist was living in Chelsea. Some rare prints of these, generally considered superior, were made before their publication in 1871. Among the best of this set are *The Pool* and *Black Lion Wharf.* Meanwhile, Whistler exhibited many paintings at the Royal Academy, one of the earliest being *At the Piano* (1860). *The White Girl,* which the academy rejected in 1863, drew great praise when it was exhibited in Paris at the Salon des Refusés. *Portrait of My Mother,* first entitled *An Arrangement in Grey and Black,* was accepted by the academy in 1872 only at the insistence of Sir William Boxall; it is now owned by the Louvre in Paris. Whistler sent other pictures, such as *The Last of Old Westminster,* to the academy, but long before his death had ceased to exhibit there, and he never became a member of the academy. Some of his best work was shown at the Grosvenor Gallery, opened by Sir Coutts Lindsay in 1877; among the paintings first seen there were such famous portraits as that of Sir Henry Irving, as well as the highly original series of *Arrangements, Harmonies,* and *Nocturnes.* It was in 1877 that John Ruskin wrote in *Fors Clavigera* of the *Nocturne, Black and Gold—The Falling Rocket,* then at the Grosvenor: "I have seen, and heard, much of Cockney impudence before now; but never expected to hear a coxcomb ask two hundred guineas for flinging a pot of paint in the public's face." Whistler brought suit for slander and was awarded damages of one farthing, which he thereafter wore on his watch chain. The costs against Ruskin were met by a public subscription. Whistler followed up the affair by a pamphlet, *Art vs. Art-Critics,* in which he first proved his cleverness in controversial satire.

He preferred to exhibit his work under conditions which he could himself direct and gave a special exhibition in 1874. Others, of prints or paintings, were held at the Fine Arts Society in 1880, 1881, 1883, 1884, and 1886. He became a member of the Royal Society of British Artists in 1884, and its president in 1886. His administration improved the quality of the exhibitions but was not commercially successful, and in 1889 he failed of re-election and many of his followers resigned. His explanation was characteristic: "It is all very simple. The Royal Society of British Artists has disintegrated—the 'artists' have come out, the 'British' remain." He failed for long to receive the recognition he deserved, but later many honors were conferred on him. He became an officer of the Legion of Honor and a member of academies in several countries, and in 1900 received gold medals at the Paris Exposition both for painting and for etching.

Whistler's etchings have been classed with those of Rembrandt. He did not keep a set of proofs or memorandums of his work and probably no complete list of his etchings, but the total is estimated at more than 400. He used an increasing economy of means; the *First Venice Series,* consisting of 12 plates published by the Fine Arts Society in 1880, and the *Second Venice Series* (53 plates; 1881) show in this respect great differences from the earlier series. The unfailing characteristics of the etchings are precision and flexibility of line and remarkable picturesqueness in the rendering of light and shade. Observation and technical skill are equally noteworthy. Outstanding among single plates are *Joe, Little Putney, Battersea Bridge, Old Chelsea,* and *Speke Hall.* Examples may be seen in the British Museum, the Metropolitan Museum of Art, the New York Public Library, the Bibliothèque Nationale, and the Venice Academy.

Whistler was also very successful in dry point and lithography. His first lithographs were made in 1877, and his London exhibition of 1883 contained a number of dry points. In 1896 about 70 lithographs were shown at the Fine Arts Society. Although he produced few pastels and water colors, some of his Venetian pastels equal anything attempted in this medium. His creed as a painter he stated in two series of *Propositions* and the lecture *Ten o'Clock* (published in 1888). One of the propositions was that a painting had "no mission to fulfill," but was a "joy to the artist, a delusion to the philanthropist, a puzzle to the botanist." Critics he considered ignoramuses, but they had their utility—"they keep one always busy, always up to the mark, either fighting or proving them idiots." For a long time, Whistler was better known in London for his pugnacity than for his art. His arrogance, his mordant wit, his sparkling bons mots, and his striking individuality were sooner recognized than his genius. His fondness for sarcasm and the severity with which he attacked those whom he did not like—and they were many—qualified him as a past master in "the gentle art of making enemies" (he published a book with this title in 1890).

His paintings exhibit a broad range of subjects. There are numerous portraits (*Miss Alexander—Harmony in Grey and Green; Rose Corder; Carlyle*); marines (*Valparaiso Harbor; Blue Wave, Biarritz; The Ocean*); and landscapes of many kinds, especially of night scenes. His method was to apply many coats of thin color instead of one or a few of great consistency, thereby guaranteeing his work greater permanance. He was above all a colorist. His work has repeatedly been compared to that of Diego Rodríguez de Silva y Velázquez, but there are important dissimilarities and Whistler must remain unique. He borrowed somewhat from Japanese art, though always subordinating these elements to his own ends.

Whistler also did some work in interior decoration, such as the Sarasate music room in Paris and the Peacock Room in the Leyland home in London. The latter is now in the Freer Gallery of Art in Washington, D.C.

Consult Lane, J. W., *Whistler* (New York 1942); Laver, James, *Whistler,* 2d ed. (London 1951); Pearson, Hesketh, *The Man Whistler* (London 1952).

WHISTLEWOOD, any tree having an easily separated bark which may be used for making whistles. In the United States the name is usually applied to the striped maple (*Acer pennsylvanicum*), a small tree or shrub common in the mountainous areas of the eastern United States and Canada. The flowers are in long axillary racemes and bloom in late spring. They are succeeded by strings of two-celled winged fruits of a yellowish green color. The slender trunks are olive green at first and then become reddish brown, striped with short, delicate white streaks. The name whistlewood is also given in the United States to the American linden or basswood (*Tilia americana*), and in Great Britain to the rowan or mountain ash, the sycamore maple, the willow, and the alder.

WHISTON, hwĭs'tŭn, **William,** English theologian and mathematician: b. Norton, Leicestershire, England, Dec. 9, 1667; d. Lyndon, Rutland, Aug. 22, 1752. He received his B.A. degree at Clare Hall, Cambridge University, in 1690, and in the following year was elected to a fellowship there. In 1693 he received his M.A. degree and was ordained a deacon and appointed chaplain to the bishop of Norwich. He became vicar of Lowestoft, Suffolk, in 1698, and deputy professor of mathematics to Sir Isaac Newton at Cambridge in 1701. Later that year, upon Newton's resignation, he succeeded to the Lucasian professorship, but, having expressed Arian views, was summarily expelled from the university in 1710. Moving to London, he published his views in *Primitive Christianity Revived* (5 vols., 1711–1712). Although he was prosecuted for heresy, the proceedings were dropped and he was permitted to remain in the Church of England. He subsequently engaged in lecturing on scientific subjects, and was one of the first to introduce lectures with experiments in London. In 1715 he founded a society for the promotion of primitive Christianity, the meetings of which were held in his home weekly for two years. Later, in 1747, he became a Baptist.

His published works include a translation of Josephus (1737), which ran through many editions; and *A New Theory of the Earth* (1696); *The Accomplishment of Scripture Prophecies* (1708); *A New Method of Discovering the Longitude* (1714); *The True Origin of the Sabellian and Athanasian Doctrines of the Trinity* (1720); *The Testimony of Phlegon Vindicated* (1732); *The Longitudes Found by the Ellipses . . . of Jupiter's Planets* (1738); and *Memoirs of the Life and Writings of Mr. William Whiston* (1749).

WHITAKER, hwĭt'ă-kĕr, **Alexander,** Anglo-American clergyman: b. Cambridge, England, 1585; d. Henrico County, Va., March 1617. He was educated at Cambridge University, receiving his B.A. degree in 1605, and his M.A. in 1608. In the latter year he was ordained in the Church of England, and in 1611 he settled in Virginia, where he was active in missionary work among the Indians at Henricopolis and Bermuda Hundreds. Whitaker baptized Pocahontas before her marriage to John Rolfe. His *Good News from Virginia,* published in London in 1613, was one of the first books written in the colonies. In it he described Virginia and urged support of the colony and conversion of the Indians.

WHITAKER, Joseph, English publisher: b. London, England, May 4, 1820; d. Enfield, Middlesex, May 15, 1895. In 1849 he founded a church monthly called the *Penny Post,* and soon thereafter established a theological publishing business. From 1856 to 1859 he was editor of the *Gentlemen's Magazine,* and in 1858 he founded the *Bookseller.* His name is commemorated in *Whitaker's Almanac,* first published in 1868. He also inaugurated the *Reference Catalogue of Current Literature* in 1874.

WHITAKER, Nathaniel, American clergyman: b. Huntington, Long Island, N. Y., November 1730; d. Hampton, Va., Jan. 26, 1795. After his graduation from the College of New Jersey (now Princeton University) in 1752, he was licensed to preach by the New York Presbytery. In 1755 he became minister of a church in Woodbridge, N. J., and in 1760 of a church in Norwich, Conn. At the request of Eleazar Wheelock (q.v.), he went to England in 1765, accompanied by Samson Occom, an Indian educated in Wheelock's school at Lebanon (now Columbia), Conn., for the purpose of soliciting funds for the school. In two years he obtained £12,000, most of which was spent for the original purpose, but some of which assisted Wheelock in founding a college in New Hampshire, chartered in 1769 as Dartmouth College (q.v.). From 1769 to 1784, Whitaker was minister of a church in Salem, Mass., and from 1785 to 1790 of one in Skowhegan, Me. During the American Revolution he was an ardent supporter of the colonial cause. His last years were spent in Virginia.

WHITBREAD, hwĭt'brĕd, **Samuel,** English politician: b. Cardington, Bedfordshire, England, 1758; d. London, July 6, 1815. He was educated at Eton College and at Christ Church, Oxford, and St. John's College, Cambridge, receiving his B.A. degree in 1784. Elected to Parliament in 1790 as Whig member for Bedford, he soon made his mark as an advocate of religious and civil liberty, the abolition of slavery, and the extension of the franchise, and as a strong opponent of the war policy of William Pitt. He took a leading part in the impeachment of Henry Dundas, 1st Viscount Melville, in 1805–1806; and against John Pitt, 2d earl of Chatham, for his mismanagement of the Walcheren Expedition in 1809. Whitbread's last years were embittered by a lengthy controversy over the rebuilding and reorganization of the Drury Lane Theatre, and he committed suicide in 1815.

WHITBY, hwĭt'bi, urban district, England, situated in the North Riding of Yorkshire, 16 miles north-northwest of Scarborough, at the mouth of the Esk River, which divides it into two parts. A fishing center and coal-exporting port, it has an excellent harbor with docks and shipyards, as well as metalworking establishments. Jet ornaments, long made here from abundant local supplies, are still manufactured, although most of the jet is now brought in from elsewhere. The section of Whitby known as West Cliff is a popular seaside resort. St. Mary's Church (13th to 16th centuries) has a cross commemorating

the Anglo-Saxon poet Caedmon, who was a monk at the abbey here. In Pannett Park there is an archaeological museum.

In 657, St. Hilda (q.v.) founded her famous abbey on the site of Whitby, then known as Streoneshalh. Here, in 664, King Oswy of Northumbria called the important Synod of Whitby, at which the Roman system of computing the date of Easter was adopted (see also EASTER). The abbey was destroyed by the Danes in 867, but was re-established by the Benedictines in 1078. The choir, north transept, and part of the nave still stand. The ruins, in Early English style, are very beautiful. Pop. (1951) 11,886.

Consult Kendall, H. P., *History of the Abbey of Whitby* (Whitby 1932); Jeffrey, P. S., ed., *Whitby Lore and Legend,* 3d ed., rev. (Whitby 1952).

WHITBY, town, Ontario, Canada, seat of Ontario County, situated on Lake Ontario, on the Canadian National and Canadian Pacific railroads, 28 miles northeast of Toronto. It is the trading center for the surrounding agricultural region and a port of entry, and has iron foundries, tanneries, and plants producing agricultural implements, mill machinery, and musical instruments. Founded in 1836, Whitby was incorporated in 1855. Pop. (1951) 7,267.

WHITCHER, hwĭch'ẽr, **Frances Miriam Berry,** American author: b. Whitesboro, N. Y., Nov. 1, 1814; d. there, Jan. 4, 1852. She was married to the Rev. B. W. Whitcher, an Episcopalian clergyman of Elmira, in 1847, the year after her humorous sketches, entitled "The Widow Bedott's Table-Talk," first appeared in Joseph C. Neal's *Saturday Gazette and Lady's Literary Museum.* They became very popular, and she contributed similar sketches to *Godey's Lady's Book.* After her death these and other articles were collected and published in *The Widow Bedott Papers* (1856) and *Widow Spriggins, Mary Elmer, and Other Sketches* (1867). See also WIDOW BEDOTT PAPERS, THE.

WHITCHURCH, hwĭt'chûrch, urban district, England, situated in Shropshire, 18 miles north of Shrewsbury and 32 miles south-southeast of Liverpool. Formerly famous for its turret clocks, it now produces metal goods and processes cheese. There is an interesting 18th century church. Pop. (1951) 6,856.

WHITCOMB, James, American public official: b. Rochester, Vt., Dec. 1, 1795; d. New York, N. Y., Oct. 4, 1852. After studying law he was admitted to the Kentucky bar in 1822, and from 1824 to 1836 practiced in Bloomington, Ind. He served in the state Senate in 1830–1831 and from 1832 to 1836, and in the latter year was appointed commissioner of the General Land Office. Moving to Terre Haute in 1841, he established a successful law practice there. Elected governor of Indiana in 1843, he served until 1848. During his tenure he reorganized the state's bonded indebtedness and promoted education and welfare. Whitcomb became a member of the United States Senate in 1849, but died before his term was completed.

WHITE, Andrew, English missionary: b. London, England, 1579; d. there, Dec. 27, 1656. A Roman Catholic, he received his education at English colleges on the Continent, and about 1605 was ordained priest at Douai, France. Returning to England, he was arrested and banished. In 1607 he entered the Jesuit novitiate at Louvain, and two years later became a member of the Society of Jesus. Subsequently he taught theology and Hebrew in Spain and Flanders, meanwhile serving on secret missions in England. He made the acquaintance of George Calvert, 1st Baron Baltimore, and in 1633 was chosen head of the Jesuit mission in Maryland, arriving in the colony early in the following year. In addition to his work among the settlers, White maintained successful missions with the Indians, and he compiled an Indian grammar, catechism, and dictionary. When William Claiborne (q.v.) gained control of Maryland in 1644, White was imprisoned and in the following year was sent to London. Brought to trial for treason, he pleaded that he had been brought to England involuntarily, and was therefore merely banished. After a few months' exile in the Low Countries, he returned secretly to England, where he spent the remainder of his life on missions and as a chaplain.

WHITE, Andrew Dickson, American educator and diplomat: b. Homer, N. Y., Nov. 7, 1832; d. Ithaca, N. Y., Nov. 4, 1918. He was graduated from Yale College in 1853 and subsequently studied at the Collège de France and the Sorbonne in Paris and at the University of Berlin. He received his M.A. degree from Yale in 1856. In 1854–1855 he served as attaché at the American legation in St. Petersburg (now Leningrad), and in 1857, shortly after his return to the United States, became professor of history at the University of Michigan. Returning to New York State in 1863 to settle his father's estate, he was elected to the state Senate, where he served until 1867. White was particularly interested in educational legislation, and he obtained passage of bills organizing the state normal school system and codifying the New York educational laws. With Ezra Cornell (q.v.), he helped to draw up the charter of Cornell University in 1865. He contributed $300,000 to the university and procured for it the federal land grant for agricultural colleges. When it opened in 1868, he was its first president and also served as professor of history, continuing in both capacities until 1885. When he left the university, he gave it his excellent historical library of over 40,000 volumes. On the acceptance of this gift, the departments of history and economics were reorganized as the President White School of History and Political Science.

While president of Cornell, White was active in public affairs. In 1871 he was a member of a commission to study and report on the desirability of annexing Santo Domingo, and in 1878 was honorary commissioner to the Paris Exposition. From 1879 to 1881, while on leave from Cornell, he served as minister to Germany. In 1884 he helped to found the American Historical Association, and served as its first president. After retiring from the university, White traveled in Europe for his health. From 1892 to 1894 he was minister to Russia, and in 1896–1897 served as a member of a commission investigating the boundary between Venezuela and British Guiana. In the latter year he was again appointed minister to Germany, serving in this post until 1902, when he retired from public life.

He was chairman of the United States delegation to the First Hague Conference (1899).

White was the author of a number of books, including *History of the Warfare of Science with Theology in Christendom* (2 vols., 1896), an enlargement of *The Warfare of Science* (1876); *Fiat Money in France* (1896), a revision *of Paper-Money Inflation in France* (1876); *Autobiography of Andrew Dickson White* (2 vols., 1905); *Seven Great Statesmen in the Warfare of Humanity with Unreason* (1910); and *The Work of Benjamin Hale* (1911).

Consult Rogers, W. P., *Andrew D. White and the Modern University* (Ithaca, N. Y., 1942).

WHITE, Charles Abiathar, American geologist and paleontologist: b. North Dighton, Mass., Jan. 26, 1826; d. Washington, D.C., June 29, 1910. In 1838 his family moved to Iowa, where he became interested in collecting fossils. After studying medicine in the office of a physician and at the University of Michigan, he attended Rush Medical College in Chicago, from which he was graduated in 1864. He practiced in Iowa City for two years, but preferred geology to medicine, and in 1866 became state geologist of Iowa, a post he retained until 1870. From 1867 to 1874 he taught geology at Iowa State University, and from 1874 to 1875 at Bowdoin College. After serving as geologist and paleontologist on various surveys, he was appointed (1879) curator of invertebrate fossils at the National Museum in Washington. From 1882 to 1892 he was geologist of the United States Geological Survey. His published works include *Manual of Physical Geography of Iowa* (1873); *Report on Invertebrate Fossils and Surveys West of the 100th Meridian* (1875); *Bibliography of North American Invertebrate Paleontology* (1878); *Review of the Fossil Ostreidae of North America* (1883); and *The Relation of Biology to Geological Investigation* (1894).

WHITE, David, American geologist and paleobotanist: b. near Palmyra, N. Y., July 1, 1862; d. Washington, D.C., Feb. 7, 1935. After being graduated from Cornell University in 1886, he joined the United States Geological Survey, for which he did research in paleobotany. From 1912 to 1922 he was its chief geologist. White's special field was paleozoic paleobotany, and he served as curator of this branch at the Smithsonian Institution in Washington from 1903 until his death. He was the author of *Fossil Flora of the Lower Coal Measures of Missouri* (1899) and many other scientific reports and papers.

WHITE, E(lwyn) B(rooks), American writer: b. Mount Vernon, N. Y., July 11, 1899. During World War I he served in the army, and in 1921 was graduated from Cornell University. After working as a reporter for several years he joined the staff of the *New Yorker* as a free-lance writer and contributing editor, for 11 years writing most of "The Talk of the Town." He then retired to Brooklin, Me., though continuing as an editorial writer and contributor of the magazine. From 1938 to 1943 he conducted the department "One Man's Meat" in *Harper's Magazine*. A notable essayist and humorist, he published *The Lady Is Cold* (1929); *Is Sex Necessary?* (with James Thurber, 1929); *Every Day Is Saturday* (1934); *The Fox of Peapack* (1938); *Quo Vadimus* (1939); *One Man's Meat* (1942); *Stuart Little* (1945); *The Wild Flag* (1946); *Here Is New York* (1949); and *Charlotte's Web* (1952). With his wife, Katharine S. White, he edited *A Subtreasury of American Humor* (1941).

WHITE, Edward Douglass, American jurist: b. Lafourche Parish, La., Nov. 3, 1845; d. Washington, D.C., May 19, 1921. He was educated at Mount St. Mary's College, Emmitsburg, Md., the Jesuit College in New Orleans, and Georgetown College in Washington. In 1861 he joined the Confederate Army, serving until 1863, when he was captured at Port Hudson and paroled. Subsequently he studied law, and in 1868 was admitted to the Louisiana bar. He served as state senator in 1874, associate justice of the state supreme court in 1879–1880, and United States senator in 1891–1894. While still a member of the Senate, he was appointed associate justice of the United States Supreme Court and in 1910 was chosen chief justice.

White wrote opinions in more than 700 cases, in most of which he assumed a middle-of-the-road position. He is best known for the rule of reason, which he first formulated in 1897, and which he applied notably in the American Tobacco Company and Standard Oil Company antitrust cases. In *Wilson* vs. *New,* he wrote the majority opinion upholding the Adamson Act of 1916, which established minimum wages for railway employees.

Consult Klinkhamer, M. C., *Edward Douglass White, Chief Justice of the United States* (Washington 1943).

WHITE, Frank, American public official: b. Stillman Valley, Ill., Dec. 12, 1856; d. Washington, D.C., March 23, 1940. He studied engineering at the University of Illinois, from which he was graduated in 1880, and a few years later moved to North Dakota, where he became active in politics as a Republican. He served in the North Dakota House of Representatives from 1891 to 1893, and in the state Senate from 1893 to 1899. During the Spanish American War he served in the Philippines as major of the 1st North Dakota Volunteer Infantry, and during World War I as a colonel in the 41st Division. White was governor of North Dakota from 1901 to 1905, and treasurer of the United States from 1921 to 1928.

WHITE, Sir George Stuart, English soldier: b. Whitehall, County Antrim, Northern Ireland, July 6, 1835; d. London, England, June 24, 1912. He was educated at Sandhurst Royal Military College, and entered the army in 1853. He served in the Indian Mutiny (1857–1859) and in the Second Afghan War (1878–1880), in which he won the Victoria Cross. In 1880 he was appointed military secretary to the viceroy of India and brevet lieutenant colonel of the Gordon Highlanders. He served as assistant quartermaster general in Egypt in 1884–1885, and distinguished himself in the Third Burmese War in 1886. He was knighted in that year, and three years later was promoted to the rank of major general. After several years' service in the North-West Frontier and Baluchistan, he was appointed commander in chief of the British forces in India, serving in this capacity from 1893 to 1897, when he became quartermaster general at the War Office in London. As commander in Natal, he defended Ladysmith for

119 days (Nov. 2, 1899–Feb. 28, 1900) against the Boers, finally being relieved by the 12th Earl Dundonald. From 1900 to 1904 he was governor of Gibraltar, and in 1903 was appointed field marshal. In 1905 he received the Order of Merit and was transferred to the governorship of Chelsea Hospital, serving in this office until his death.

WHITE, Gilbert, English clergyman and naturalist: b. Selborne, Hampshire, England, July 18, 1720; d. there, June 26, 1793. He was graduated from Oriel College, Oxford, in 1743, became a fellow of the college in the following year, and received his M.A. degree in 1746. After taking deacon's orders in 1747, he acted as curate to an uncle, Charles White, in Swarraton. Having been ordained priest, he was for a short period in 1751 curate to the vicar of Selborne. Appointed dean of his college in 1752, he soon thereafter became curate of Durley, near Bishop's Waltham, Hampshire. Although he failed to secure the provostship of Oriel in 1757, he obtained the vicarage of Morton-Pinkney, Northamptonshire, which was in the gift of his college. He never resided there, however, and throughout his life remained closely associated with the Hampshire parish which he made famous. About 1758 he gave up the Durley curacy for that of Faringdon, near his home in Selborne, though for a time he acted as curate of West Deane, Wiltshire.

White's great classic, *The Natural History and Antiquities of Selborne,* was published at the end of 1788, with the date 1789 on the title page. It consists of letters to two friends, Thomas Pennant, author of *British Zoology,* and Daines Barrington, who devised the form of the *Naturalist's Journal* which White kept from 1767, when he discontinued the *Garden Kalendar,* begun in 1751. In preparing the section on antiquities, which he compiled only when he had been induced to publish his work, he was greatly assisted by Richard Chandler, the classical antiquary and traveler. *The Natural History of Selborne* has won the enthusiastic admiration of readers of widely varying tastes, and has been published in many editions. White was a keen observer, and his descriptions of plants and animals contain very few errors.

Consult Martin, E. A., *Bibliography of Gilbert White, the Naturalist and Antiquary of Selborne,* rev. and enl. (London 1934); Scott, W. S., *White of Selborne and His Times* (London 1946).

WHITE, Henry, American diplomat: b. Baltimore, Md., March 29, 1850; d. Pittsfield, Mass., July 15, 1927. He was privately educated in the United States and Europe and entered the United States diplomatic service. After serving as secretary of the American legation in Vienna, he became second secretary (1884–1886) and then first secretary (1886–1893) of the embassy in London. During his stay there he frequently acted as chargé d'affaires, and in 1886 was special American representative at an international conference for the abolition of sugar bounties. White's diplomatic service was interrupted by the administration of Grover Cleveland, but in 1897 he was reappointed secretary of the embassy in London by President William McKinley, and occupied that office until 1905, when he became ambassador to Italy. He was ambassador to France in 1907–1909, and in 1910 served as head of the American delegation to the Fourth Pan American Conference in Buenos Aires and as special ambassador to Chile. As American representative at the Algeciras Conference on Moroccan affairs in 1906, he helped settle the differences between France and Germany. In 1917–1918 he was regional director of the American Red Cross, and in 1918–1919 served as a member of the United States delegation to the Paris Peace Conference, in which he worked on the Commission of International Régime of Ports, Waterways, and Railways.

Consult Nevins, Allan, *Henry White: Thirty Years of American Diplomacy* (New York 1930).

WHITE, Henry Kirke, English poet: b. Nottingham, England, March 21, 1785; d. Cambridge, Oct. 19, 1806. The son of a butcher, he was first apprenticed to a stocking weaver and later to an attorney, in whose office he devoted his spare time to the study of Latin and Greek and to writing poetry. In 1803 he published *Clifton Grove, a Sketch in Verse, with Other Poems,* which won him the attention and friendship of Robert Southey and other men of letters. He obtained a sizarship at St. John's College, Cambridge, in 1804, and, after a year's preparation, began studying there. His early death from tuberculosis shocked his friends, and his work tended to be overvalued by his contemporaries. After his death his manuscripts were placed in the hands of Southey, who edited his poems, letters, and other writings, and published them under the title *The Remains of Henry Kirke White . . . with an Account of His Life* (2 vols., 1807). Of his principal poem, *The Christiad,* only a fragment is extant. White will be longest remembered for his hymn *Oft in danger, oft in woe.*

WHITE, Henry Seely, American mathematician and educator: b. Cazenovia, N. Y., May 20, 1861; d. Poughkeepsie, N. Y., May 20, 1943. He was graduated from Wesleyan University in 1882 and received his Ph.D. degree at Göttingen in 1891. From 1892 to 1905 he was professor of pure mathematics at Northwestern University, also serving as secretary of the faculty there in 1903–1905. In the latter year he became professor of mathematics at Vassar College and continued to teach there until his retirement in 1936. White was president of the American Mathematical Society in 1907–1908, and was elected to the National Academy of Sciences in 1915. He was associate editor of the *Transactions* of the American Mathematical Society from 1902 to 1906, and editor from 1907 to 1913. He specialized in geometry and published *Plane Curves of the Third Order* (1925).

WHITE, Horace, American journalist: b. Colebrook, N. H., Aug. 10, 1834; d. New York, N. Y., Sept. 16, 1916. He was graduated from Beloit College in 1853, and in the following year became city editor of the Chicago *Evening Journal,* and in 1855 Chicago agent of the Associated Press. In 1857 he joined the editorial staff of the Chicago *Tribune,* and in the following year reported the Lincoln-Douglas debates for that paper. During the Civil War he was the *Tribune's* Washington correspondent and also served as clerk of the Senate Committee on Military Affairs. With two other newspapermen, he headed a syndicate for the publication of Civil War news in 1864–1865. Returning to Chicago,

he was editor in chief of the *Tribune* until 1874, when he went to New York as treasurer of the Oregon Railway & Navigation Company. In 1881 he joined the staff of the New York *Evening Post,* and from 1899 to 1903 served as editor in chief. His editorials opposing the Spanish American War, the annexation of Hawaii, and the Philippines campaign attracted wide notice. In 1908, Governor Charles Evans Hughes appointed him to a state commission on speculation in securities and commodities.

White published a number of notable works, including *Money and Banking, Illlustrated by United States History* (1895) and *The Life of Lyman Trumbull* (1913), and he edited several French and Italian works on finance.

WHITE, Horatio Stevens, American educator: b. Syracuse, N. Y., April 23, 1852; d. Cambridge, Mass., Dec. 12, 1934. After graduating from Harvard University in 1873, he studied in Europe and in 1878 was admitted to the New York bar. From 1876 to 1878 he was assistant professor of Greek and Latin at Cornell University, and from 1878 to 1883 assistant professor of German. He became professor of German in 1883, and head of the German department in 1891. In 1902 he went to Harvard as professor of German, becoming professor emeritus in 1919. White edited *Selections from Lessing's Prose, Text and Notes* (1888); *Selections for German Prose Composition* (1891); and Appleton's Twentieth Century Series of German Classics (1901–1905); and he wrote *Memorial of Willard Fiske* (3 vols., 1920–1922) and *Willard Fiske—A Biographical Study* (1925).

WHITE, Howard Judson, American architect: b. Chicago, Ill., Feb. 21, 1870; d. there, Dec. 18, 1936. After working as a draftsman for several architects in Chicago, he was employed by the firm of D. H. Burnham & Co. in 1898. When the firm was reorganized as Graham, Burnham & Co. in 1912, he became a member of it, and, in 1917, of its successor firm, Graham, Anderson, Probst & White. Among the many notable buildings he designed were the Field Building, Field Museum, Wrigley Building, and Union Station in Chicago; the Equitable Building and the Chase National Bank in New York; the Selfridge Stores in London; and the Union Trust Building and Union Station in Cleveland.

WHITE, Hugh Lawson, American lawyer and politician: b. Iredell County, N. C., Oct. 30, 1773; d. near Knoxville, Tenn., April 10, 1840. After serving as a volunteer against the Cherokees in 1792, he studied law and began to practice in Knoxville in 1796. He was judge of the Tennessee Superior Court (1801–1807), state senator (1807), United States district attorney (1808), again state senator (1809), and presiding judge of the Tennessee Supreme Court of Errors and Appeals (1809–1815). From 1812 to 1827 he served as president of the Bank of the State of Tennessee, and from 1821 to 1824 as United States commissioner for the adjustment of claims against Spain. In 1825 he was elected to the United States Senate, succeeding Andrew Jackson. As a strict constructionist, he opposed the making of internal improvements by the federal government and was a leader in the movement which resulted in the withdrawal of government deposits from the Second Bank of the United States. From 1834 he engaged in a political feud with Jackson. In 1836 he was nominated for the presidency, but, carrying only Georgia and Tennessee, failed to prevent the election of Martin Van Buren, who was Jackson's choice. In 1838 he declared himself a Whig, and two years later he resigned from the Senate because of his unwillingness to vote for the subtreasury bill, as he had been instructed to do by the Tennessee legislature.

WHITE, Israel Charles, American geologist: b. Monongalia County, Va. (now W. Va.), Nov. 1, 1848; d. Baltimore, Md., Nov. 25, 1927. He was graduated from West Virginia University in 1872, and in 1875 became assistant geologist of the Pennsylvania Geological Survey, a post he retained until 1884, when he joined the United States Geological Survey, with which he remained until 1888. From 1877 to 1892 he was professor of geology at West Virginia University, and from 1897 until his death was superintendent of the West Virginia Geological Survey. White was one of the founders of the Geological Society of America, and served as its president in 1920. He is known for the anticlinal theory for locating oil and gas deposits, which he formulated about 1883.

WHITE, James, Canadian geographer: b. Ingersoll, Ontario, Canada, Feb. 3, 1863; d. Ottawa, Ontario, Feb. 26, 1928. He was educated at the Royal Military College, Kingston, and in 1884 joined the Geological Survey of Canada as a geographer, a post he retained until 1899, when he was appointed chief geographer of the Department of the Interior. In 1909 he became secretary of the Royal Conservation Commission, and served as its deputy head from 1913 to 1921, when he resigned to become technical adviser to the minister of justice. In 1927 he was elected chairman of the Geographic Board of Canada. His published works include *Altitudes in Canada* (1901); *Dictionary of Altitudes in Canada* (1903); *The Atlas of Canada* (1906); *Place-Names in Quebec* (1910); *Place-Names in Northern Canada* (1910); *Place-Names in the Thousand Islands* (1910); and *Boundaries and Treaties* (1913).

WHITE, James William, American surgeon: b. Philadelphia, Pa., Nov. 2, 1850; d. there, April 24, 1916. He was graduated in 1871 from the University of Pennsylvania with the degrees of M.D. and Ph.D., and in 1871–1872 served on Louis Agassiz' staff in the Hassler Expedition to the West Indies and around South America. He served successively as resident physician at the Philadelphia Hospital (1873) and at the Eastern State Penitentiary (1874–1876), and in 1876 was attached to the surgical staff of the hospital of the University of Pennsylvania, where he lectured on genitourinary surgery. From 1887 to 1900 he was professor of clinical surgery at the university, and from 1900 until his retirement in 1911, John Rhea Barton professor of surgery. In 1915 he was attached to the American Ambulance Hospital in Neuilly, France. He left a bequest of $400,000 to the University of Pennsylvania.

From 1892 to 1916, White edited the *Annals of Surgery,* and he published *An American Text-Book of Surgery* (with W. W. Keen, 1892); *Genito-Urinal Surgery and Venereal Diseases*

(with Edward Martin, 1897); and *Human Anatomy* (1906).

WHITE, John Blake, American painter: b. near Eutaw Springs, S. C., Sept. 2, 1781; d. Charleston, S. C., Aug. 24, 1859. After studying law in Charleston, he went to London, where he studied painting under Benjamin West from 1800 to 1803. Returning to the United States, he attempted unsuccessfully to establish himself in Charleston and then in Boston as an artist, and in 1804 resumed the study of law in Charleston, where he was admitted to the bar in 1808. He built up a flourishing practice and served several terms as a member of the South Carolina legislature. Meanwhile he continued to paint, and it is as an artist that he is best known. White's most celebrated picture, *Minister Poinsett Unfurling the United States Flag in the City of Mexico During the Mexican Riots,* was destroyed during the Civil War. Among those that have been preserved are four in the Capitol in Washington: *Battle of Fort Moultrie; General Marion Inviting a British Officer to Dinner; Mrs. Motte Directing Marion and Lee to Burn Her Mansion to Dislodge the British;* and *Sargents Jasper and Newton Rescuing American Prisoners from the British.* He also painted many portraits, among them ones of John C. Calhoun, Charles C. Pinckney, and Henry Middleton, and he was the author of a number of plays, including *Foscari, or the Venetian Exile* (1806); *The Mysteries of the Castle* (1807); *Modern Honor* (1812); *The Triumph of Liberty, or Louisiana Preserved* (1819); and *Intemperance* (1839).

WHITE, John Hazen, American clergyman: b. Cincinnati, Ohio, March 10, 1849; d. Sea Breeze, Fla., March 16, 1925. He was graduated from Kenyon College in 1872, and from the Berkeley Divinity School, Middletown, Conn., in 1875. Ordained in the Protestant Episcopal Church in 1876, he served as rector of Grace Church, Old Saybrook, Conn., from 1878 to 1881; of Christ Church, Joliet, Ill., from 1881 to 1889; and of St. John's Church, St. Paul, Minn., from 1889 to 1891. In the latter year he became warden of the Seabury Divinity School, Faribault, Minn., remaining in this office until 1895, when he was consecrated bishop of Indiana. On the division of the diocese in 1899, White chose the northern portion with the title of bishop of Michigan City.

WHITE, John Williams, American Greek scholar: b. Cincinnati, Ohio, March 5, 1849; d. Cambridge, Mass., May 9, 1917. After being graduated from Ohio Wesleyan University in 1868, he studied in Germany and traveled in Greece. In 1873 he published an edition of Sophocles' *Oedipus Tyrannus,* and in the following year became tutor of Greek at Harvard. After receiving his M.A. and Ph.D. degrees there in 1877, he was appointed assistant professor of Greek, and in 1884 full professor, retiring in 1909. He was of considerable assistance to Charles W. Eliot in introducing new methods at Harvard. White was an excellent teacher, and he was responsible for a number of innovations, including the wide use of sight translations in the study of Latin and Greek and the production of classical Greek plays in Greek. In 1879 he helped to organize the Archaeological Institute of America, and he served as its president for five years. He was also one of the founders of the College Series of Greek Authors, and with James B. Greenough began the *Harvard Studies in Classical Philology.* His published works include a number of textbooks, many papers, and *The Verse of Greek Comedy* (1912) and *The Scholia on the Aves of Aristophanes* (1914).

WHITE, Joseph Blanco, British theological writer: b. Seville, Spain, July 11, 1775; d. near Liverpool, England, May 20, 1841. His father was Irish and his mother Spanish, and he was brought up in Seville, where he studied at the university and was ordained subdeacon (1796) and priest (1800) in the Roman Catholic Church. In 1802 he was appointed chaplain in the Chapel Royal of San Fernando at Seville, but in 1810, having lost his faith, he withdrew from the priesthood and went to England, where he edited (1810–1814) a patriotic newspaper, *Español,* which was circulated in Spain (partly by the British government) to assist the national struggle against Napoleon. In 1814, White was ordained in the Church of England. He began contributing in 1820 to the *New Monthly,* edited by Thomas Campbell (q.v.), and in 1825 published *Evidences Against Catholicism.* In 1826 he received an M.A. degree from Oxford, and settled there at Oriel College, where he became friendly with John Henry Newman, Edward Pusey, and other leaders of the Oxford movement, who learned from him much concerning Roman Catholic theology. From 1832 to 1835, White lived in Dublin as a tutor to Archbishop Richard Whately's family, and then became a Unitarian.

White is best known to literature by his sonnet *Night and Death,* which Samuel Coleridge, in a letter of 1827, declared to be the finest in the English language. Among his other published works are *Letters from Spain; by Don Leucadio Doblado* (1822); *Second Travels of an Irish Gentleman in Search of a Religion* (2 vols., 1833), written in answer to Thomas Moore's *Travels of an Irish Gentleman in Search of a Religion;* and *Observations on Heresy and Orthodoxy* (1835).

WHITE, Peregrine, the first child born in New England of English parents: b. on board the *Mayflower,* off Cape Cod, Mass., Nov. 20, 1620; d. Marshfield, Mass., July 22, 1704. He was the son of William and Susanna White. During the colonists' first winter at Plymouth his father died, and in 1621 his mother married Governor Edward Winslow (q.v.). This was the first wedding in New England. Because of his birth, White received a grant of 200 acres of land from the General Court of Massachusetts. A leading citizen of Marshfield, he filled numerous civil and military offices during his long life.

WHITE, Richard Grant, American essayist and critic: b. New York, N. Y., May 23, 1821; d. there, April 8, 1885. He was graduated from the University of the City of New York (now New York University) in 1839, and then studied medicine and law, being admitted to the bar in 1845. From 1846 to 1859 he was a critic of music, art, and literature for the *Morning Courier and New-York Enquirer,* and in music particularly was one of the best critics of the period. After a short period with the New York *World* (1860–1861), he joined the staff of the New

York Custom House, serving as chief clerk of the marine revenue bureau, a post he retained until 1878.

White was best known as a Shakespearean scholar. He contributed articles on Shakespeare to *Putnam's Magazine* and other periodicals, and in 1854 published *Shakespeare's Scholar.* His 12-volume edition (1857–1866) of *The Works of William Shakespeare* was republished in 1883 as the popular 3-volume *Riverside Shakespeare.* He also wrote a number of philological studies, including *Words and Their Uses* (1870) and *Every-day English* (1880). Among his other published works are *Handbook of Christian Art* (1853); *The New Gospel of Peace* (4 vols., 1863–1866), a satire on the Copperheads; *England Without and Within* (1881); a novel, *The Fate of Mansfield Humphreys* (1884); and the posthumous *Studies in Shakespeare* (1886). White was one of the most influential critics of his time. Although he was at times dogmatic and quick to generalize, his criticism was vigorous, acute, and frequently brilliant. His scholarship was substantial, his style readable and often marked by satire.

WHITE, Stanford, American architect: b. New York, N. Y., Nov. 9, 1853; d. there, June 25, 1906. The son of Richard Grant White (q.v.), he entered the employ of the architectural firm of Gambrill & Richardson in 1872, and remained there for 12 years. At first strongly influenced by the Romanesque work of Henry H. Richardson, whose chief assistant he was in the construction of Trinity Church, Boston, he subsequently modeled his designs on classical forms. In 1878–1879 White traveled in Europe. On his return he formed with Charles F. McKim and William R. Mead the influential firm of McKim, Mead & White. Among the numerous notable buildings he designed were Madison Square Garden (the old building on Madison Square, since demolished), Madison Square Presbyterian Church (also demolished), the Players Club, Washington Arch, and the Century and Metropolitan clubs, in New York; many fine residences in New York, Newport, and the Berkshires; several buildings for the restoration of the University of Virginia; and the Battle Monument at the United States Military Academy, West Point. His career was cut short in 1906, when he was murdered on the roof of Madison Square Garden by Harry K. Thaw.

WHITE, Stewart Edward, American fiction writer: b. Grand Rapids, Mich., March 12, 1873; d. San Francisco, Calif., Sept. 18, 1946. After graduation from the University of Michigan in 1895, he studied at Columbia Law School for two years, but devoted most of his time thereafter to writing. During World War I he served as a major of field artillery. His published works, most of which are adventure tales set in the West, include *The Westerners* (1901); *The Blazed Trail* (1902); *The Forest* (1903); *The Mystery* (1907); *The Rules of the Game* (1909); *The Land of Footprints* (1912); *Gold* (1913); *The Rediscovered Country* (1915); *The Gray Dawn* (1915); *Simba* (1918); *The Forty Niners* (1918); *The Rose Dawn* (1920); *Daniel Boone* (1922); *On Tiptoe* (1922); *The Glory Hole* (1924); *Credo* (1925); *Back of Beyond* (1927); *Dog Days* (autobiography, 1930); and *Stampede* (1942).

WHITE, Sir Thomas, English merchant: b. Reading, England, 1492; d. Oxford, Feb. 12, 1567. He engaged in business as a clothier from 1523, and in 1535 was master of the Merchant Taylors' Company. Increasingly prosperous, he made large loans to Coventry and Bristol, and held civic office as alderman (1544) and sheriff (1547) of London. In 1553 he helped to promote the Muscovy Company, and in the same year was elected lord mayor, in which office he was of considerable assistance to Mary Stuart on her accession to the throne. White was deeply interested in education. He was one of the founders of the Merchant Taylors' School, and in 1560 he founded St. John's College, Oxford, to which he gave a liberal endowment.

WHITE, Walter (Francis), American author and Negro leader: b. Atlanta, Ga., July 1, 1893; d. New York City, March 21, 1955. A graduate of Atlanta University (1916), he became assistant secretary of the National Association for the Advancement of Colored People in 1918, was made the organization's acting secretary in 1929, and its secretary in 1931. In his work with the association he did much to improve conditions of American Negroes, and to further good interracial relations. He was awarded the Spingarn Medal in 1937 for his fight against lynching. His published works include *Fire in the Flint* (novel, 1924); *Flight* (novel, 1926); *Rope and Faggot—A Biography of Judge Lynch* (1929); *A Rising Wind* (1945); and *A Man Called White* (autobiography, 1948).

WHITE, William, American clergyman: b. Philadelphia, Pa., April 4, 1748; d. there, July 17, 1836. He was graduated from the College of Philadelphia (forerunner of the University of Pennsylvania) in 1765, and in 1770 was admitted to the diaconate of the Church of England by the bishop of London, and two years later to the priesthood by the bishop of Norwich. Upon his return to Pennsylvania, he became assistant minister of Christ Church, Philadelphia, and in 1776 rector, an office he held until his death. In 1777 he was chaplain to the Continental Congress, and in 1782 the degree of D.D., the first honorary degree of the University of Pennsylvania, was conferred on him. The meeting which issued the summons for a convention preparatory to organizing the Protestant Episcopal Church was held at his house in 1784, and he presided over its first general convention in 1789. With William Smith, he prepared the American revision of the Book of Common Prayer. He originated the principle of joint participation by the laity in church government, and he drafted the first constitution of the church. In 1786 he was elected bishop of Pennsylvania and was consecrated in England in the following year. From 1796 until his death he served as presiding bishop of the church. During his tenure he endeavored to conciliate conflicting views among Episcopalians and to cooperate with other denominations. He was an early sponsor of the Sunday school movement.

White's published works include *Christian Baptism* (1808); *Lectures on the Catechism* (1813); *Comparative Views of the Controversy Between the Calvinists and the Arminians* (2 vols., 1817); and *Memoirs of the Protestant Episcopal Church in the United States of America* (1820).

WHITE, William Alanson, American neurologist and psychiatrist: b. Brooklyn, N. Y., Jan. 24, 1870; d. Washington, D.C., March 7, 1937. He studied at Cornell University from 1885 to 1889, and in 1891 was graduated with the degree of M.D. from Long Island Medical College. From 1892 to 1903 he served as assistant physician at the Binghamton State Hospital for the Insane, and after 1903 as superintendent of St. Elizabeth's Hospital, Washington, D.C. He was professor of nervous and mental diseases at Georgetown University from 1903, and at George Washington University from 1904, and he also lectured at the United States Naval and Army Medical School. White was an early follower of Sigmund Freud, and he introduced new methods of psychiatric treatment in the United States. He served as president of the American Psychiatric Association and the American Psychoanalytic Association. He prepared several medical treatises with Smith Ely Jelliffe (q.v.), and was the author of *Mental Mechanisms* (1911); *Principles of Mental Hygiene* (1917); *Foundations of Psychiatry* (1921); *Insanity and the Criminal Law* (1923); *Outlines of Psychiatry* (11th ed., rev., 1926); *The Major Psychoses* (1928); and *Crimes and Criminals* (1933).

WHITE, William Allen, American writer and journalist: b. Emporia, Kans., Feb. 10, 1868; d. there, Jan. 29, 1944. His father, Dr. Allen White, was a country doctor and merchant, and his mother, Mary Hatton White, a pioneer school teacher. When he was 10 years old, the family moved to El Dorado, and he received his preparatory education there. He attended the College of Emporia and the University of Kansas, setting type in newspaper offices to help support himself. He became so attracted to newspaper work that he left college before graduation to become business manager of the El Dorado *Republican,* and to hold various other jobs in journalism. In 1895 he bought the Emporia *Gazette,* then an obscure country paper, and embarked on a campaign opposing William Jennings Bryan. His fervid editorial, "What's the Matter with Kansas?" made him famous overnight. His first published volume, a collection of short stories called *The Real Issue and Other Stories* (1896), proved popular, and was followed by other volumes, including *The Court of Boyville* (1899); *In Our Town* (1906); *A Certain Rich Man* (1909); *In the Heart of a Fool* (1918); and *The Martial Adventures of Henry and Me* (1918). Never an orthodox adherent of the Republican Party, he supported Theodore Roosevelt's Bull Moose campaign in 1912. In 1923 his eloquent editorial entitled "To an Anxious Friend" won the Pulitzer Prize. In 1924, White became so incensed over the Republican selection for the governorship of Kansas that he ran for office himself on an independent ticket. Although he lost the election, he polled a vote of 149,811. He went to Haiti in 1930 on a presidential commission and advocated the withdrawal of United States troops. In 1933 he went to Moscow and for a time reported conditions in Russia for the New York *Times* and the North American Newspaper Alliance. His autobiography, *Forty Years on Main Street,* appeared in 1937. In 1940 he served as chairman of the Committee to Defend America by Aiding the Allies, and he campaigned for Wendell L. Willkie. In the following year he became a member of the American Palestine Committee and of the Committee on Negro Americans in Defense Industries. By the time of his death he had made the Emporia *Gazette* one of the best-known newspapers in the United States, and he was known as "the Sage of Emporia."

Among his other published works are *Woodrow Wilson: The Man, the Times, and His Task* (1924); *Calvin Coolidge: The Man Who Is President* (1925); *Masks in a Pageant* (1928); *A Puritan in Babylon* (1938); and *The Changing West* (1939).

Consult Clough, F. C., *William Allen White of Emporia* (New York 1941); Rich, Everett, *William Allen White, the Man from Emporia* (New York 1941); Johnson, Walter, *William Allen White's America* (New York 1947).

His son, William L(indsay) White (1900–), also became a writer and journalist. His published works include *What People Said* (1938); *Journey for Margaret* (1942); *They Were Expendable* (1942); *Report on the Russians* (1945); *Report on the Germans* (1947); *Lost Boundaries* (1948); *Land of Milk and Honey* (1949); and *Back Down the Ridge* (1953).

WHITE, William Hale (pseudonym Mark Rutherford), English novelist: b. Bedford, England, Dec. 22, 1831; d. Groombridge, Kent, March 14, 1913. He studied theology at New College, a Congregationalist seminary, until 1851, and subsequently preached occasionally in Unitarian chapels. In 1854 he entered the civil service as a clerk at Somerset House. Transferring to the Admiralty in 1858, he became assistant director of contracts there in 1879 and held this post until his retirement in 1891. White is best known for his trilogy: *The Autobiography of Mark Rutherford* (1881); *Mark Rutherford's Deliverance* (1885); and *The Revolution in Tanner's Lane* (1887). In addition to other novels, he wrote *John Bunyan* (1905), and translated (1883) Baruch Spinoza's *Ethica Ordine Geometrico Demonstrata.*

WHITE, Sir William Henry, English naval architect: b. Davenport, England, Feb. 2, 1845; d. London, Feb. 27, 1913. He was educated at the Royal School of Naval Architecture, and from 1867 to 1883 was employed in the construction department of the Admiralty, becoming chief constructor. In addition, he lectured on naval design at the Royal Naval College from 1870 to 1881. Between 1883 and 1885 he organized and directed the warship building department of Armstrong & Co. Returning to government service, he was director of naval construction at the Admiralty from 1885 to 1902. During these years he was responsible for the design of more than 200 British naval vessels. White was knighted in 1895. After his retirement he frequently served as a technical consultant, and helped to design the *Lusitania* and the *Mauretania.* He was the author of *Manual of Naval Architecture* (1877).

WHITE, Sir William Thomas, Canadian statesman: b. Bronte, Ontario, Canada, Nov. 13, 1866. He was graduated from the University of Toronto in 1895, and was admitted to the bar in 1899. After serving for some years on the staff of the Toronto *Telegram,* he became connected with the assessment department of Toronto. From 1900 to 1911 he was general manager of the National Trust Company. White was an opponent of the

Reciprocity Treaty between Canada and the United States, and although a Liberal in politics was instrumental in defeating the Laurier Ministry. He was Minister of Finance in the Conservative Cabinet of Sir Robert L. Borden from October 1911 to 1919. He was knighted in 1916.

WHITE ANTS. See TERMITES.

WHITE BASS. See BASS.

WHITE BOOK, a government publication in Germany and Portugal, corresponding to the British Blue Book and the Yellow Book of France. See BLUE BOOKS.

WHITE BOYS, an illegal association formed in Ireland in 1760, composed of starving day-laborers, evicted farmers and others in a like condition, who used to assemble at nights to destroy the property of landlords or their agents, the Protestant clergy, the tithe collectors or any others that had made themselves obnoxious in the locality. In many cases they did not confine their acts of aggression merely to plunder and destruction, but even went the length of murder.

WHITE BRETHREN, a sect which caused a commotion in Europe about the beginning of the 15th century. A priest whose origin is unknown, his nationality being variously alleged as Spanish, French and Scotch, made his appearance in Lombardy, and said that he was the prophet Elias, and had come back from heaven to give notice of the coming destruction of the world. He had thousands of followers, who were arrayed in white, and carried large crucifixes, as they marched from the Ligurian Alps into central Italy. Pope Boniface IX caused him to be apprehended, and he was burned as an impostor. The White Brethren then dispersed.

WHITE CAMELIA, The Knights of the, formed in May 1867 at New Orleans, was the largest of the revolutionary orders called into existence by the misgovernment of Reconstruction. Its principal strength was in the Gulf States, farther south than the notorious Ku Klux Klan (q.v.). The organization was as follows: A supreme council for the United States; a grand council in each State; a central council in each congressional district and councils in each county. Each council was divided into circles and groups. The officers of the council were known as commander, lieutenant-commander, etc.; the members were called «brothers.» The objects of the order were, to nullify radical legislation, to reduce the influence of Negroes in politics, to prevent amalgamation of the races and to defend the white race against radical encroachment. The White Brotherhood and the White League were closely related orders that existed in the same territory a few years after the White Camelia had disintegrated. Consult Brown, *Lower South American History* (1902); *Constitution and Ritual of the Knights of the White Camelia,* in West Virginia University Documents relating to Reconstruction, Nos. 1 and 2.

WHITE CAPS, in American history, the lawless bands in southern Indiana, who, from 1880, undertook the regulation of the manners and morals of that section. During the Civil War, the Knights of the Golden Circle (q.v.) flourished in the same parts. The White Caps dressed differently in different parts of the country which they terrorized. Where they were regularly organized and did the most mischief they generally had nearly a full uniform or regalia. They wore white paper foolscaps, with paper masks, and coats of coffee sacking. To make the coats they merely cut arm or sleeve holes in the sides of coffee sacks close to the bottoms and holes in the bottoms to put their heads through.

WHITE CATTLE (of Chillingham), certain cattle preserved in a semi-wild state in Chillingham Park, England. They are pure white, except the muzzle, which is black, and the horns which are tipped with black. The white color on the body, however, is artificially produced, the owner causing all spotted calves to be killed. They are now generally believed to be the descendants of the mountain bull or urus (see Ox), which was wild in Gaul at the time of Caesar's invasion, and the stock whence modern breeds of domestic English cattle have been partly derived. Dawkins, however, considers them the last surviving representatives of a still more primitive race, the gigantic ox, known by its remains in caves to have occupied Great Britain in the Pleistocene Period. He considers them much modified in every respect by their small range and their contact with man.

WHITE CLOVER, OAK PINE. See CLOVER; OAKS; PINE.

WHITE COLORS, *in painting,* white pigment or white lead. Baryta yields several commercial varieties of white color, largely used for adulterating white lead. The substances used are heavy spar, the native sulphate, and witherite, the native carbonate, of baryta. An artificial sulphate of baryta is also used in permanent white. Zinc white or Chinese white is a hydrated oxide of zinc and pearl white is yielded by the nitrate of bismuth. A fine chalk yields Spanish white, and whiting is ordinary ground chalk. Quicklime is a sanitary white for external walls, etc.

WHITE CROSS, a self-supporting American organization which had a large membership throughout the Union, having for its motto, «Truth, Charity and Philanthropy,» and for its emblem cross bandages of white on a field of red. It was founded in 1898 by Mrs. Jane Creighton of Portland, Oreg., and its object was the care of wounded and sick American soldiers and sailors, and aid to the widows, and orphans of those who had fallen in battle, or died of disease or accident.

WHITE CROSS SOCIETY, an association founded in England, in 1883, by the bishop of Durham, and introduced in the United States in that year by the Rev. B. F. de Costa, rector of the Protestant Episcopal Church of Saint John the Evangelist, New York, who became a Roman Catholic in 1899. The objects of the society are «to urge upon men the obligation of personal purity; to raise the tone of public opinion upon the subject of morality; to secure proper legislation in connection with morality.» Those who become members of the society promise «by the help of God» to treat all women with respect and endeavor to protect them from wrong and degradation; to endeavor to put down all indecent language and coarse jests; to maintain the law of purity as equally

binding on men and women; to endeavor to spread these principles and try to uplift younger brothers and to use every possible means to fulfil the command, «Keep thyself pure.» The society seeks to forward its objects «by the full presentation of those spiritual truths which form distinguishing characteristics of Christianity and demonstrate its unalterable hostility to every form of impurity.» The Society has been established also in Canada.

WHITE-CROWNED SPARROW. See SPARROW.

WHITE EAGLE, Order of. See ORDERS (ROYAL) AND DECORATIONS.

WHITE ELEPHANT, an elephant affected with albinism. Such animals, always rare, are highly esteemed by some Eastern potentates and are considered sacred in Siam, where the animal has become a national symbol, so that Siam is called «the land of the white elephant,» and one of the highest decorations conferred by its rulers is that of the Order of the White Elephant. A specimen purchased by the late P. T. Barnum from King Theebaw, of Burma, was brought to the United States in 1884. It stood seven feet and a half high and the face, ears, front of trunk, fore feet and part of breast were of a light ash color. Figuratively, a present which does one much more harm than good, or more generally any nominal advantage which has this effect. It is reported that when in old times the ruler of Siam desired to ruin any one, he made him a present of a white elephant. The sacred elephant has an enormous appetite, and, being sacred, it would be a crime to let it die, so that the gift generally entailed ruin on the recipient.

WHITE-EYES, one of the numerous small insectivorous birds of the New Zealand region, called blight-birds locally, because they feed so largely upon the plant-lice which torment garden plants and orchard trees. They belong to the genus *Zosterops,* which is variously classified by ornithologists, but seems most nearly related to the titmice. Other species are scattered elsewhere throughout the Old World tropics. All are neatly but not gaudily dressed have in most cases a conspicuous ring of white feathers around the eye and build pretty nests. The genus is interesting, further, from the fact that many of its species are confined to small islands, apparently affording examples of the effect of isolation (q.v.).

WHITE FEATHER, a symbol of cowardice; a term introduced in the days when cock-fighting was in vogue. As a thoroughbred game cock has no white feathers, a white feather was a proof that the bird was not game.

WHITE FLY, a minute insect of the family *Aleyrodidæ,* closely allied to the aphids and coccids, which infest the leaves of plants, usually on the lower side, and are pests in greenhouses. (See GREENHOUSE INSECTS). They are covered with a whitish mealy secretion, and when young also secrete wax. The group is not a large one and does not do much harm to fruit or forest trees, except that one species (*Aleyrodes citri*) has been prevalent in Florida orange groves since about 1890. The evil they do results not only from their sucking the nutritive juices of the plants, but from the spread of smut-fungus which is promoted by their presence. Consult Howard, 'The Insect-book' (New York 1901).

WHITE FRIARS, a name formerly given to the friars of Our Lady of Mount Carmel, because they wore a white scapular and cloak over their brown habit. See CARMELITES.

WHITE GOAT. See ROCKY MOUNTAIN GOAT.

WHITE HATS, a badge of the Democratic party in Flanders in the 14th century. White hats were used in England to denote radical proclivities, because Orator Hunt (1773–1835), the great demagogue, during the Wellington and Peel administration, used to wear a white hat.

WHITE HELLEBORE, a liliaceous plant of the genus *Veratrum,* a source of insect-poison, the principle of which is the alkaloid veratrin. See also HELLEBORE.

WHITE HOUSE, the official residence of the President of the United States, in Washington, D. C. The name arose from the fact that the building is constructed of freestone and painted white. It is 170 feet long, 86 feet deep and two stories in height. It has an Ionic portico, the main entrance faces north. Reception rooms are on the first floor and the private apartments of the President are on the second floor. Among the reception rooms are the Blue Room used for diplomatic functions, the East Room used for public receptions, and the Red and Green rooms. The original official residence for the President was begun in 1792; it was first occupied by Adams, in 1800. In 1814 it was burned by the British and four years later was rebuilt. In 1903 executive offices connected with the main building were built on the grounds. These were greatly enlarged in 1934 by excavating the basement and extending it to the south, adding a new story in the former attic.

WHITE LADY, an apparition which figures in the legends and traditions of various countries, as presenting herself to give warning of death and other momentous events in royal and titled households. The White Lady is supposed to be an ancestress of the family she visits, and the association of such a legend with a family name is regarded as a guarantee of noble and ancient lineage. The one-time imperial house of Hohenzollern had its White Lady, and Hampton Court, England, is said to be invaded at times by a supernatural visitor, although there seems to be some doubt whether it is a White Lady or the ghost of Henry VIII. The earliest historical instance of the apparition is recorded as having occurred in the 15th century and is celebrated under the name of Bertha of Rosenberg, in Bohemia. Similar appearances are said to have been witnessed in the Schloss at Berlin, one as recent as 1879.

WHITE LEAD, a white pigment very largely used in painting. Many processes have been devised for its manufacture. The old Dutch method was to expose sheet lead in coils, placed in earthenware jars partly filled with vinegar, to the combined action of air, moisture and carbonic acid gas. This was done by immersing the jars with their contents in decomposing horse manure which furnished the heat and carbonic acid gas necessary for the

process. The English process, which is the one by which most of the white lead is made, differs from the Dutch process by the use of fermenting tan bark instead of manure. The pots containing the lead and dilute acetic acid or vinegar are piled in rows in the so-called stacks and surrounded with the fermenting tan bark. After about three months the lead is removed and purified. The process is slow and the methods of purification dangerous to the workmen, but the resulting white lead is of the best quality. In the French method a solution of basic lead acetate is first prepared by the action of an impure acetic acid on litharge or lead oxide. Carbonic acid gas is then passed through this solution and the white lead precipitated. White lead is also produced electrolytically, by employing a solution of sodium-nitrate, preferably in a cell of wood and a porous diaphragm. The anode is of lead and the cathode of copper. When the current is turned on, nitric acid appears at the anode as lead nitrate and from the cathode appears caustic soda. The lead hydroxide obtained is later treated with sodium bicarbonate to secure the carbonate of lead. White lead is subject to frequent adulteration. It may be tested for purity by making a solution of the powder in acetic acid, which should take up all the lead and leave the adulterant. White lead is a basic carbonate of lead of somewhat variable composition. That formed by the Dutch and English processes may be represented by the formula $2PbCO_3,Pb(OH)_2$.

WHITE LEAGUE, The, in American history, a popular name for a semi-military organization, gathered to repress the negroes of the State of Louisiana, who, it was asserted, were meditating insurrection. The organization had its inception in New Orleans in 1874 and on the refusal of the city authorities to allow the landing of a cargo of firearms, which the league had imported from New York, a riot ensued which resulted in more than 100 deaths. The league afterward became a powerful factor in Louisiana politics.

WHITE METAL, a term used for an alloy of lead, antimony and tin used for bearings in machinery. Also applied to many other alloys that have a white color.

WHITE MONKS. See *Bernardines* under ORDERS, RELIGIOUS.

WHITE MOUNTAINS, a group of peaks and hills, or a range of mountains, principally in New Hampshire, in the northern part; but which extend into Maine on the east and on the west are connected with the Green Mountains in Vermont. They belong to the Appalachian system. Mount Katahdin, in Maine, is the highest elevation on the eastern rim, and in New Hampshire there are about 20 peaks, with deep narrow valleys and long lines of rounded foot-hills. The peaks are in two groups; the eastern or White Mountain group proper and the Franconia group, separated by a tableland varying from 10 to 20 miles in width. The principal summits of the eastern group are, beginning at the Notch and passing around to Gorham, Mounts Webster, Clinton, Pleasant, Franklin, Monroe, Washington, Clay, Jefferson, Adams and Madison. Of these Mount Washington is the highest and is indeed the highest mountain summit in New England, being 6,293 feet above the level of the sea. The principal peaks of the Franconia group are Pleasant, Lafayette, Liberty, Cherry and Moosehillock. Near the southern border of the plateau are Whiteface, Chocorua, Red Hill and Ossipee, and in the southeast, Kearsarge. North of the plateau and near the upper waters of the Connecticut, are several elevations, among which are the twin mountains known as Stratford peaks. The plateau is deeply furrowed by several streams. The geological formation of the White Mountains is almost entirely of ancient metamorphic rocks. In many of the peaks the upper portion is composed of huge masses of naked granite or gneiss, and the debris which in the course of ages has clothed the lower portion with a coarse gravelly soil, possesses only enough of the constituents of vegetable life to support those trees and shrubs which will grow in the hardest and poorest soil. Land slides, the result of dislodgment of bowlders and loosely adherent soil after heavy rains, are not infrequent. One of these occurred in the notch of the White Mountain group in August 1826 and destroyed a whole family named Willey. The most noteworthy of many waterfalls among the mountains are the Artist's Fall in North Conway; the Silver Cascade, a beautiful thread of water descending from far up the side of Mount Webster; Ripley's Falls, on a tributary of the Saco, below the Willey house, the lower one, Sylvan Glade cataract, falling at an angle of 45 degrees, 156 feet, in a stream from 50 to 75 feet in width; the falls of the Ammonoosuc, which in a course of 30 miles descends over 5,000 feet; the Berlin Falls on the Androscoggin, descending over 200 feet in the course of a mile, and the Crystal Cascade and Glen Ellis Fall, near the Glen house, on a tributary of the Androscoggin. Of the "notches," or passages (not rent through the solid granite of the mountains by some violent convulsion of nature as has often been supposed, but carved by the slow action of rivers), there are five; the White Mountain Notch, two miles in length and at its narrowest point only 22 feet wide, through which the Saco River passes; the Franconia Notch, which permits the passage of the Pemigewasset; the Pinkham Notch, through which a branch of the Saco and one of the Androscoggin find their way, and the Grafton and Dixville notches, through which flow the Androscoggin and one of its tributaries. The first two of these are those best known. "The Flume" at Franconia Notch is the most noted of those narrow waterways excavated through the rock, though there are others hardly inferior to it in attractiveness. Among the other objects of interest in the Franconia group is the "Old Man of the Mountain," a well-defined profile of the human face formed by three projecting rocks. (See FRANCONIA). At the base of the mountain lies a beautiful lakelet one-fourth of a mile long and one-eighth wide, called "Profile Lake," or the "Old Man's Washbowl." Five miles south of the notch is the "Basin," a circular bowl-like cavity 45 feet in diameter and 28 in depth, produced by the whirling of large stones in a natural hollow in the rock by the current. It is filled with clear sparkling water, which flows down the mountains in a succession of beautifully clear

cascades. The "Pool," in the same vicinity, is a natural well in the solid rock 60 feet in diameter and 190 feet deep, of which 40 feet is water. The White Mountains were first visited by a white man, Darby Field, of Pascataquac, in 1642, when with two Indians he ascended Mount Washington. Later in the same year Thomas Gorges and companions traveled up the Saco and explored the mountains and the plateau and discovered the sources of the Saco, Connecticut, Androscoggin and Kennebec rivers. The White Mountains are a famous summer resort.

WHITE OAK SWAMP, Battle of. See Frayser's Farm, Battle of.

WHITE PLAINS, city, New York; seat of Westchester County; altitude 200 feet. It is situated 25 miles north-northeast of New York City, and is served by the New York Central Railroad. The Bronx and Mamaroneck rivers border the city and there are lakes nearby. White Plains is a residential community, with a considerable retail trade, and manufactures of plumbing and heating equipment, textiles, chemicals, cables, and pipe. The Westchester County civic center is here, with an auditorium; as well as Good Counsel College, founded 1923, for women.

White Plains was settled in 1683, and in early years, up to the American Revolution, was active in iron mining. It was the meeting place of the provincial assembly which ratified the Declaration of Independence in 1776 and in the same year was the scene of the Battle of White Plains. It was incorporated as a village in 1866; as a city in 1916. Government is of the commission form. Pop. (1950) 43,466.

WHITE PLAINS, Battle of, in the American Revolution. On Oct. 21, 1776, following his evacuation of New York City and the repulse of the British in the Battle of Harlem Heights, (September 16), Washington established his headquarters at White Plains, N. Y. On the evening of October 27 Col. John Haslet with about 1,600 American troops had taken possession of Chatterton Hill, a commanding eminence on the west side of the Bronx River, and on the morning of the 28th, reinforced by a small additional force under Gen. Alexander McDougall and two pieces of cannon under command of Alexander Hamilton, he fortified his position as well as time would allow. On the morning of that day Sir William Howe advanced with his forces in two columns (numbering about 13,000 men) on the American army posted along the Bronx. Perceiving the importance of the position on Chatterton Hill and regarding it as the only assailable point of the American army, Howe sent Leslie with a strong detachment to cross the Bronx and attack it in front, while Colonel Rahl with a Hessian regiment was ordered to cross the river a quarter of a mile below and attack Haslet in flank. The hill was carried with great difficulty, the Americans retreating in good order and without being pursued. The British troops rested that night on Chatterton Hill. The next day, October 29, a skirmish took place between the two armies; but Howe, finding the Americans still too strongly posted to be attacked with safety, waited for reinforcements. These arrived on the evening of the 30th; but a storm coming on, the Americans took advantage of it and withdrew to the still stronger position of Newcastle, two miles above, which they had previously fortified. Afraid to attack them in this position, Howe fell back to the junction of the Harlem and Hudson rivers and encamped on Fordham Heights, and Washington withdrew his army leisurely into New Jersey and made his headquarters at Hackensack.

The loss of the Americans in the Battle of White Plains and the skirmish of the succeeding days were nearly 300 in killed, wounded and prisoners, and that of the British about the same. The battlefield was marked and set aside as White Plains Battlefield Site, a historical park, in 1926.

WHITE RIVER, in Arkansas, has its rise in the Ozark Plateau, in the northwestern part of the state, flows northeast into Missouri, being dammed to form Lake Taneycomo, and enters Arkansas again in Marion County, then flows southeast to the Mississippi River. It enters the Mississippi through several channels, some of which pass through the mouth channels of the Arkansas River. Except in the highlands of the Ozark Plateau, the greater part of the course of the river is through marshy forest land. It is navigable to Batesville, about 300 miles. The total length is 690 miles.

WHITE RIVER, in Indiana, the chief branch of the Wabash in the state, is formed by the confluence, in Pike County, of the East and West Fork, which have their rise near the eastern boundary of the state. From the junction of the two forks to the mouth of the White, where it enters the Wabash, is 50 miles; the total length from the source of the West Fork is 350 miles; from the source of the East Fork, 300 miles.

WHITE RIVER, in South Dakota, the chief river of the southwestern portion of the state, rising in Dawes County, northwestern Nebraska, and flowing northeast into South Dakota, through Shannon and Washington counties, thence easterly to the Missouri River, which it joins a little south of Oacoma. The territory drained is locally known as the Bad Lands. Total length about 325 miles.

WHITE RIVER JUNCTION, village, Vermont; in Hartford town in Windsor County; altitude 340 feet. It is situated on the Connecticut River, at the mouth of the White River, nine miles north-northeast of Woodstock, and is served by the Central Vermont, and the Boston and Maine railroads. It is a commercial center for a large agricultural region in Vermont and New Hampshire. There are extensive railroad yards. White River Junction is a traffic center, and has much transient trade. Woodstock, near by, is a summer resort and has winter sports as well. There is a public library, a high school, and a United States veterans hospital established in 1938. The business section is on one side of White River; the residential, on the other. Pop. (1950) 2,365.

WHITE SAGE. See Eurotia; Goosefoot.

WHITE SANDS NATIONAL MONUMENT. A remarkable accumulation of granular gypsum in the Tularosa Desert in Otero and

Dona Ana counties, N. Mex. It consists mostly of dunes five to 50 feet high, of dazzling whiteness, and covers an area of 140,247.04 acres. Most of the material is nearly pure gypsum containing about 95 per cent of that mineral. To the north it grades into quartz sand. Attempts were made to utilize the deposit for manufacture of plaster of Paris, but local demand for this product was small and cost of long distance shipment was too great. The gypsum was carried into the basin in solution from the adjoining mountains and after crystallizing by evaporation of the water has been blown by the wind into dunes. Some of it is brought to the surface by ground water. The national monument was created in 1933. White Sands Proving Ground, a testing ground for rockets, is to the southeast in Dona Ana County.

WHITE SEA, gulf, northern USSR, a large inlet between Kola Peninsula on the west and Kanin Peninsula on the east. Near its mouth, and on the eastern side, is a branch called the Gulf of Mezen, which receives the waters of the river Mezen. The inner part of the sea sends off three large arms, namely Kandalaksha Gulf, between the USSR and Finland; Onega Bay, which receives the river Onega; and Dvina Gulf (Gulf of Archangel), into which flows the Northern Dvina River. Of the islands in the sea, Solovetsk is the largest (180 square miles). The White Sea is comparatively shallow, and is frozen over from October to May. Arkhangelsk (Archangel), at the mouth of the Northern Dvina, is the leading port of northern Russia. Other ports on the shores of the sea are Onega and Kem. Its area is about 36,000 square miles.

WHITE SULPHUR SPRINGS, town, Montana; Meagher County seat; altitude 5,200 feet. It is situated 54 miles east of Helena, on the White Sulphur Springs and Yellowstone Park Railroad. The county was named for Gen. Thomas Francis Meagher. In a cattle and sheep region, the town holds an annual rodeo on Labor Day. The springs from which the town derives its name are used for medicinal purposes. Pop. (1950) 1,025.

WHITE SULPHUR SPRINGS, town, West Virginia; in Greenbrier County; altitude 1,917 feet. It is a residential community and health resort, 83 miles southeast of Charleston and only a few miles from the Virginia border. It is served by the Chesapeake and Ohio Railway. It was settled about 1750 and its mineral springs have been popular since the early 1800's; Presidents Van Buren, Tyler, and Fillmore used it as a summer residence. There is a federal hatchery for bass and trout here. Government is by mayor and council. Pop. (1950) 2,643.

WHITE SWELLING, any severe disease of the joints resulting from chronic inflammation in the bones, cartilages, or membranes. The knee, ankle, wrist and elbow are the joints most subject to this form of disease. It is distinguished from simple inflammation of the synovial membrane (synovitis) by the fact that the synovial membrane passes into pulpy degeneration. Amputation is frequently necessary. The disease may be local or constitutional in origin; in the latter case it may be due to rheumatism, gout, syphilis, or pyemia.

WHITEAVES, Joseph Frederick, Canadian paleontologist: b. Oxford, England, Dec. 26, 1835; d. Aug. 8, 1909. He studied at the University of Oxford in 1858–1861 and made investigations of the land and fresh-water mollusca and fossils of the oolitic rocks in the vicinity of Oxford, adding considerably to the information possessed. He moved to Canada in 1861, was engaged in geological investigations in Montreal and Quebec in 1861–1862, and in 1863–1875 he was curator of the museum and secretary of the Natural History Society of Montreal. He made a special study of the land and fresh-water mollusca of Lower Canada in 1867–1873. He was appointed to the Canada Geological Survey in 1875, became its paleontologist in 1876, and in 1877 was appointed zoologist and assistant director. He was one of the original fellows of the Royal Society of Canada.

WHITEBAIT, a small fish, which is regarded by naturalists as merely the fry of the herring or of similar fish. The whitebait fishery is actively prosecuted on some parts of the British coast, particularly in the estuary of the Thames, where the whitebait is very abundant in spring and summer, beginning to appear in the end of March or early in April. Adult whitebait are caught on the coasts of Kent and Essex during winter, and in this condition are about six inches in length. Whitebait is found also in the Forth. It is much in demand as a delicacy for the table. At the time when ordinarily captured, whitebait are only from one and one half to four inches in length. They are caught by means of bag nets sunk four or five feet below the surface of the water. For several months they continue to ascend the river in shoals with the flood tide and descend with the ebb tide, not being able to live in fresh water.

The whitebait has the body more compressed than the mature herring; belly, serrated; lower jaw, longer than the upper; scales, very soft, small and thin, and very easily rubbed off; color, silvery white, greenish on the back. The food of the whitebait seems to consist of minute crustaceans. It is probable that under the name whitebait the fry of all the British herring family (Clupeidae)—the pilchard, the sprat and the shad—are indiscriminately taken and used like the fry of the herring.

WHITECHAPEL, hwīt'chăp-ĕl, district London, England. It forms three wards of Stepney metropolitan borough, east of the City of London. It is one of the poorest portions of the metropolis, and was formerly notorious for its criminal population. From 1888 to 1891 it was the scene of the atrocities of the mysterious Jack the Ripper. Within its boundaries are the Tower of London and London Hospital, and it is intersected by Whitechapel Road. The name is derived from a former medieval chapel, whence all distances east of London were calculated.

WHITEFIELD, hwīt'fēld, **George,** English evangelist, founder of the Calvinist Methodists: b. Gloucester, Dec. 16, 1714; d. Newburyport, Mass., Sept. 30, 1770. He was sent to the grammar school of St. Mary de Crypt at Gloucester, and at 18 entered as servitor at Pembroke College, Oxford, where he became acquainted with the Wesleys, and

joined the small society which procured them the name of Methodists. Hearing of his devotional tendencies, Dr. Benson, bishop of Gloucester, made him an offer of ordination at 21, which he accepted, and he was ordained a deacon in 1736. Such was his powerful and exciting preaching, that, after his first sermon at Gloucester, a complaint was made to the bishop that he had driven several people mad; on which the prelate observed that he hoped the madness would not be forgotten before the next Sunday. He for some time supplied a curacy at Dummer, in Hampshire, but the next account sent him by the Wesleys of their progress in Georgia excited in him a desire to assist in their labors, and he arrived at Savannah in May 1737. Observing the deplorable want of education in the colony, he projected an orphan-house for which he determined to raise contributions in England, where he arrived in the beginning of 1739. Although discountenanced by many of the clergy, Bishop Benson did not scruple to confer on him priest's orders: and on going to London the churches in which he preached were incapable of holding the crowds assembled. He then adopted the practice of preaching in the open air, which he first carried out at Kingswood, near Bristol, among the colliers, on whom his discourses produced a surprising effect, and whose vicious manners and habits he visibly improved. He afterward preached in the open air in Bristol, and in Moorfields, Kennington, and other places in the neighborhood of London, to vast assemblages of people. In August 1739, he again embarked for America, and made a tour through several of the provinces, where he preached to immense audiences, with an effect vividly portrayed in the autobiography of Benjamin Franklin. He arrived at Savannah in January 1740, where he laid the foundation of the orphan-house, and after making another extensive tour, returned to England, in March 1741. During his absence his cause had been declining at home, and the differences between him and Wesley on the doctrines of election and reprobation deprived him of many followers. After visiting many parts of England, Scotland and Wales, where he married in 1741, he again returned to America (1744), and remained there nearly four years. His preaching met with great opposition in New England at this time and Harvard College put forth a «testimony» against him. Returning to England in July 1748 he was soon after introduced to the Countess of Huntington, who made him one of her chaplains. A visit to Ireland and two more voyages to America followed, and for several years his labors were unremitting. He preached at Exeter, N. H., the day before his death, and also at Newburyport. He is buried beneath the pulpit of the Federal Street Church at Newburyport. His works were published in 1771–72. Consult Gillies, 'Memoirs' (1772); Tyerman, L., 'Life of Whitefield' (1876–77).

WHITEFISHES, a name given in the United States to various species of salmonoid fishes of the genus *Coregonus* and sometimes to those of *Argyrosomus,* more properly designated ciscoes. *Coregonus* has a comparatively small and nearly toothless mouth, the premaxillary bones broad and with the edge nearly vertical, and the lower jaw short. The thin cycloid scales are much larger than in the salmons and trouts, and the caudal fin is deeply forked. Internally, the stomach is horse-shoe shaped and provided with very numerous pyloric caeca, and the swim-bladder is very large. The species, about 15 in number, though some ichthyologists recognize many more, are confined to the clear lakes of the northern portions of the northern hemisphere often extending into the Arctic regions and sometimes there becoming anadromous. Wherever found they are highly valued for food. North America has about eight species. The common whitefish (*C. clupeiformus*) has its centre of distribution in the Great Lakes, but extends into the various lake systems of New York and southern Canada. It reaches a length of two feet and may be distinguished from the related species by its numerous and long gill-rakers, the toothless mouth and the elevated but not compressed back. As generally in the whitefishes, the color is olivaceous above and white below. It receives various local names from the fishermen, such as buffalo-back; and the variety landlocked in Otsego Lake at the head of the Susquehanna River is known as the Otsego bass. During the greater part of the year the whitefish remains in the deeper waters of the lakes, moving about in schools which change their feeding grounds with considerable regularity. Being toothless they feed only upon small animals, such as crustaceans, snails and insect larvæ, the first being by far the most important part of their diet. During the late fall and early winter the schools congregate on the shallows to spawn; in the act of spawning the female rises to the surface and is immediately followed by a male which mingles the sperm with the stream of eggs issuing from her vent. The eggs are about one-eighth of an inch in diameter and sink to the bottom, where most of them are eaten by the small fishes and mud-puppies which swarm on the spawning grounds. They develop slowly and require several weeks to hatch, the exact time depending upon the temperature of the water. Each female produces from 10,000 to 75,000 eggs, depending upon her size.

Besides the enemies affecting the eggs and young the adult whitefish are preyed upon by the large pike and lake-trout which follow the schools, and to a less extent by smaller predaceous fishes. The extensive development of the fisheries, which are prosecuted most vigorously at the very season when the spawning fish are most accessible on the shallows, has so depleted the numbers of the whitefish that the fisheries are now dependent upon artificial propagation for their maintenance. The methods are essentially the same as those employed in the artificial propagation of the shad, though many modifications in detail have been found necessary. Hundreds of millions of eggs are now annually taken and hatched under the auspices of the United States and State commissions of fisheries. Such extensive and even greater operations are required to sustain these fisheries at a point of production equal to satisfying the demand of the market. These figures represent the American catch alone and during the same year the Canadian fisheries prob-

ably yielded about 40,000,000 pounds more. Whitefish are sold fresh or are frozen immediately after capture and placed in cold storage at a temperature several degrees below freezing and in this condition shipped, especially during the winter, to all parts of the country.

Other species of *Coregonus* are found in the Great Lakes as well as in other lakes particularly northward and westward, but at the present time none are so highly valued as the common whitefish. An important one is the shadwaiter or round whitefish (*C. quadrilateralis*). The genus *Argyrosomus,* however, includes two species of great and increasing importance, though inferior in quality to the common whitefish. The genus differs from *Coregonus* chiefly in the projecting lower jaw, larger mouth and horizontal premaxillary bones. The numerous species are similarly distributed in North America, which has eight, Europe and Asia, and except for their great activity and predatory mode of life their habits in general resemble those of the true whitefishes. The cisco whiting or lake herring (*A. artedi*) is about a foot long, bluish or greenish above, with dark, speckled silvery sides. It abounds in shallow waters of the Great Lakes and, as indicated above, is of great commercial value. The moon-eye cisco (*A. hoyi*) has a very large eye and the sides are brilliantly silvery. It is about a foot long and is the object of a considerable fishery in the western part of Lake Michigan. It spawns in November in relatively deep water. A third important species of this genus is the blue-fin whitefish (*A. nigripennis*), distinguished from all of the preceding which have pale fins by the blue-black color of its pectorals, anals and ventral. It attains a length of 18 inches and is plentiful in the deep waters of Lake Michigan and the small lakes of Minnesota and Wisconsin and thence northwestward to Athabasca.

Whitefishes seldom take the hook, but are captured by means of pound, trap and gill nets and to a smaller extent with seines. The pound and trap nets are arranged in lines which sometimes reach to a distance of 10 or 12 miles from shore, while the gill nets are set in deep water and are weighted to the bottom.

WHITEHALL, London, England, a street leading from Parliament Square to Trafalgar Square, containing several public offices, and named after a palace that once stood there. The building, known as the Horse Guards, the office of the commander in chief of the army, is so called in consequence of being the station where that part of the troops usually do duty. The original Whitehall succeeded a palace built by Hubert de Burgh before the middle of the 13th century. It afterward came into the possession of the archbishops of York, was inhabited by Wolsey (under the name of York Place), then passed to Henry VIII and was called Whitehall. Charles I was executed in front of Whitehall and he was led to the scaffold out of one of the windows. Oliver Cromwell died in Whitehall. In 1697 the building was destroyed by fire, except the banqueting hall, which had been added by James I, according to a design of Inigo Jones, in 1619. This portion still remains and chiefly consists of one room, of an oblong form and 40 feet high. The ceiling, representing the apotheosis of James I, was painted by Rubens and was retouched by Cipriani. This building was long a royal chapel, but it now contains the museum of the Royal United Service Institution.

WHITEHALL, village, New York, in Washington County; altitude 123 feet; at the southern end of Lake Champlain and northern terminus of the Barge Canal; midway between New York and Montreal on the Hudson-Champlain Trail; 77 miles north of Albany; on the Delaware and Hudson Railroad. The village stands in a narrow valley, at the foot of Skene's Mountain. It is an industrial community, and a railroad division point, with silk mills and railroad shops. Grist mills and lumber mills, paint factories, boat-building yards, and machine shops have place in its industrial history. It has a public library and a high school. Whitehall was a scene of action in both the French-and-Indian and the Revolutionary wars. It was settled in 1759 by Maj. Philip Skene, a British army officer, and some 30 families; the settlement was at first called Skenesborough, in his honor. In the Revolution, Skene, as a Tory, lost the land holdings on which he held patents. In 1776 an American garrison was stationed at Whitehall; fearing capture by Burgoyne, the soldiers and townsfolk destroyed the fort and the houses, and abandoned the place. At the close of the war nearly all the people returned and claimed their former holdings. In 1806 the place was incorporated as the village of Whitehall. In 1812, when the Lake Champlain towns and villages were again near the center of danger, a fort and blockhouse were built. The Champlain Canal was the predecessor of the present Barge Canal section as a unit in a waterway from the Hudson to Canada. Pop. (1950) 4,457.

WHITEHAVEN, city, England, seaport and important coal-mining center in Cumberland, situated on a bay of the Irish Sea, 40 miles southwest of Carlisle. It is well built, and has a town hall, customhouse, market house, public library, public baths, with swimming pond; a theater, a good harbor and a deepwater floating dock. There is a considerable shipping trade, coals, iron ore, pig iron, and steel rails being exported and American and other produce imported. The manufactures comprise sailcloth, cordage, anchors, nails, cement, alabaster, earthenware, candles, and soap. Iron shipbuilding also is carried on and there are blast-furnaces, iron- and brass-foundries, engineering works, flour- and saw-mills; breweries, and a tannery. There are here extensive coal and iron mines. The coal mines, which have been worked since the 17th century, extend some miles under the sea, and coal is mined beneath the town. Pop. (1951) 24,624.

WHITEHEAD, Alfred North, English mathematician and philosopher: b. Ramsgate, Isle of Thanet, Kent, Feb. 15, 1861; d. Cambridge, Mass., Dec. 30, 1947. Educated at Sherborne School and Trinity College, Cambridge, from which he received his B.A. degree in 1884, he served as lecturer and senior lecturer on mathematics at Trinity College, 1885–1911. He lectured on applied mathematics and mechanics, and later was reader in geometry at University College of the University of London. He was professor of applied mathematics at the Imperial College of

Science and Technology of the University of London, 1914–1924. He then went to the United States as professor of philosophy at Harvard University, a post he held until his retirement in 1936. Like his most distinguished pupil, Bertrand Russell, Whitehead viewed philosophy from the standpoint of mathematics, and together they wrote the monumental *Principia Mathematica* (1910–1913), in which the deduction of mathematics from formal logic was achieved. Whitehead's idealistic philosophy, which he called the philosophy of organism, was concerned with "the becoming, the being, and the relatedness of actual entities."

His writings include *A Treatise on Universal Algebra* (1898); *The Principle of Relativity* (1922); *Religion in the Making* (1926); *The Function of Reason* (1929); *Nature and Life* (1934); and *Essays in Science and Philosophy* (1946).

WHITEHEAD, Charles, English poet: b. London, 1804; d. Melbourne, Australia, July 5 1862. He was engaged in a London mercantile house until 1857 when he went to Australia and entered journalism. He was the author of numerous poems, plays and sketches, among which are *The Solitary* (1831); *The Autobiography of Jack Ketch* (1834); *The Cavalier,* drama (1836); *Richard Savage* (1842), subsequently dramatized; *Smiles and Tears,* or *the Romance of Life* (3 vols. 1847); *Life and Times of Sir Walter Raleigh* (1854) Consult Bell, Mackenzie, *Charles Whitehead, a Forgotten Genius* (1884).

WHITEHEAD, Cortlandt, American Protestant Episcopal bishop: b. New York, Oct. 30, 1842; d. Niagara Falls, Sept. 18, 1922. He was graduated from Yale in 1863 and from the Philadelphia Divinity School in 1867. Ordained to the priesthood in 1868 he was engaged in pastoral work in Colorado for three years and was rector of the Church of the Nativity, South Bethlehem, Pa., 1870–1882. In January 1882 he was consecrated bishop of Pittsburgh.

WHITEHEAD, William, English poet: b. Cambridge, Feb. 12, 1715; d. London, April 14, 1785. He was educated at Winchester and Clare Hall, Cambridge, was appointed secretary and registrar of the order of the Bath in 1755, and in 1757 was appointed poet laureate, in succession to Colley Cibber (q.v.). His identity is frequently confused with that of the satirist Paul Whitehead. He was the author of the tragedies: *The Roman Father* (1750); and *Creusa, Queen of Athens* (1754); the comedy, *The School for Lovers* (1762); a farce, *The Trip to Scotland* (1770); and numerous minor poems. His collected works were edited and published with a memoir by William Mason (1788).

WHITEHILL, Clarence Eugene, opera singer: b. Marengo, Iowa, Nov. 5, 1871; d. New York City, Dec. 1932. He studied under L. A. Phelps and was engaged as a church singer until, following the advice of Madame Melba, he went to Paris to study for the operatic stage. He studied under Giraudet and Sbriglia in Paris and in 1900 made his debut successfully at Brussels. In 1901 he made his first appearance at the Opéra Comique in Paris. He studied the great Wagnerian rôles with Cosima Wagner and was highly successful in them. He appeared at Bayreuth, and at Covent Garden, London; after 1909 with the Chicago Opera Company; after 1920 a member of the Metropolitan Opera Company.

WHITEING, Richard, English novelist: b. London, July 27, 1840; d. London, June 29, 1928. He was educated privately and began his career in journalism in 1866 with a series of satirical sketches on social and political topics afterward republished as *Mr. Sprouts—His Opinions* (1867). He became leader writer on the *Morning Star* and later Paris correspondent for various New York, London and Manchester papers and then joined the editorial staff of the London *Daily News,* a position he resigned in 1899. Among his writings are *The Democracy* (1876); *The Island* (1888); *No. 5 John Street* (1899); *The Life of Paris* (1900); *The Yellow Van* (1903); *All Moonshine* (1907); *My Harvest* (1915); *Both Sides of the Curtain* (with Dame Geneviève Ward 1918); Film *No. 5 John Street* (1921).

WHITELOCKE, hwīt'lŏk, **Bulstrode,** English statesman: b. London, Aug. 2, 1605; d. Chilton Park, Wiltshire, July 28, 1675. Educated at Oxford he studied law at the Middle Temple, was called to the bar in 1626, and entered Parliament as member for Stafford. He was elected to the Long Parliament of 1640 from Great Marlow, was chairman of the committee for drawing up Stafford's charges of impeachment, and one of the commissioners appointed to treat with the king at Oxford. As a member of the Westminster Assembly (1643) he opposed the adoption of Presbyterianism, and as a commissioner of the Great Seal (1649) withheld consent to the king's death. In 1623 he was ambassador to Sweden, where he concluded a treaty with Queen Christina, and on his return was speaker of the House of Commons (1656), and one of Cromwell's lords (1657). From his manuscripts have been published *Memorials of the English Affairs from the Beginning of the Reign of Charles I to the Restoration* (1682; new ed. 1852); *Memorials of English Affairs from Bruce to the End of the Reign of James I* (1709), and other works.

WHITESTONE, N. Y., a community in the Borough of Queens, New York City; on the East River (north shore of Long Island). It is connected with the Borough of The Bronx by the Bronx-Whitestone Bridge, opened 1939 and owned and operated by the Triborough Bridge Authority.

WHITETHROAT, a bird, either of two species of Old World warblers—*Curruca cinerea,* the greater, and *C. sylviella,* the lesser whitethroat; or a hummingbird (*Leucochloris albicollis*) of Brazil; or a whitethroated sparrow (*Zonotrichia albicollis*), commonly known in the eastern United States, where it is a migrant, as Peabody bird.

WHITEWASH, a milky fluid produced by mixing good slaked lime with water: used as a cheap coating for walls, fences, etc. When mixed with a little size and sometimes colored it is used on interior walls under the name of calcimine.

WHITEWATER, Wis., city in Walworth County; altitude 822 feet; on Whitewater Creek;

43 miles southwest of Milwaukee; on the Chicago, Milwaukee, St. Paul and Pacific Railroad. The surrounding region is agricultural, and the city has canning and food processing plants. There are some small establishments producing such articles as clothing and hardware. In the city are a state teachers' college (coeducational: founded 1866). First settlement of the site was made in 1839. Pop. (1940) 3,689; (1950) 5,101.

WHITFIELD, hwĭt'fēld, or **WHITFELD, Henry,** English clergyman: b. 1597; d. Winchester, England, 1657?. Of the date of his birth and his early life nothing is definitely known. He appears to have been appointed to the living of Ockley, Surrey, in 1616, but having protected several Puritan clergymen during the Laudian persecution incurred the displeasure of Archbishop William Laud, which was further increased by his refusal to read to his parishioners from the *Book of Sports.* He, therefore, emigrated to New England in 1637 with many followers and was one of the founders of Guilford, Conn. In 1650 he returned to England and was minister at Winchester.

His writings include *Some Helpes to Stirre up to Christian Duties* (3d ed., 1636); *The Light Appearing More and More Toward the Perfect Day* (1641); and *Strength out of Weakness* (1652).

WHITFIELD, Robert Parr, American geologist: b. New Hartford, N. Y., May 27, 1828; d. 1910. He studied natural history and geology almost unaided, was assistant on the New York State geological survey in 1856–1876, and in 1872 was attached to the United States Geological Survey. He was instructor in geology at the Rensselaer Polytechnic Institute in 1872–1875, professor in 1875–1878 and for many years after 1887 was curator of the American Museum of Natural History in New York.

WHITGIFT, hwĭt'gĭft, **John,** English prelate: b. Great Grimsby, Lincolnshire, 1530?; d. Lambeth, Feb. 29, 1604. He was educated at Pembroke Hall, Cambridge, and after the accession of Elizabeth took holy orders (1560) and was made chaplain to Cox, bishop of Ely. In 1563 he was appointed Lady Margaret professor of divinity at Cambridge, in which office he gained a high reputation by his lectures on the book of Revelations and the Epistle to the Hebrews, and in 1567 was elected master of Pembroke Hall. Soon after, the queen made him her chaplain and master of Trinity College, Cambridge, and the same year he also became regius professor of divinity. He was made dean of Lincoln in 1571, and in 1576 bishop of Worcester, and, being also vice president of the marches of Wales, made constant use of both the temporal and spiritual powers to put down Roman Catholicism and Puritanism within the limits of his jurisdiction. In 1583 he became archbishop of Canterbury, and soon exacted from every clergyman in the church a subscription to the three points of the queen's supremacy, the lawfulness of the common prayer and ordination service, and the truth of the whole 39 articles. Making use of the court of high commission he removed from positions in the church all nonconformists. In 1585 the star chamber, at his instigation, passed ordinances for the regulation of the press, by which no one was allowed to print except in London, Oxford, and Cambridge; the number of printers was to be determined by the ecclesiastical commissioners; and none but a few special printers were to be suffered to print any book, matter or thing whatsoever until it should be perused and allowed by the archbishop of Canterbury and the bishop of London; and every one selling books contrary to the intent of the ordinance was to be imprisoned for three months. In 1586 he was sworn of the Privy Council and framed the statutes of cathedral churches. The hospital and grammar school at Croydon were founded by Whitgift.

WHITING, hwī'tĭng, **Arthur,** American musician: b. Cambridge, Mass., June 20, 1861; d. Beverly, Mass., July 20, 1936. He studied music in Munich at the Royal Music School with Josef Rheinberger. He was a pianist and composed orchestral and chamber music, as well as numerous songs, pianoforte pieces, concertos and sacred music. His series "University Concerts" were well received at Harvard, Yale and Princeton and other colleges.

WHITING, George Elbridge, American musician and composer: b. Holliston, Mass., Sept. 14, 1842; d. Cambridge, Mass., Oct. 14, 1923. He early displayed musical talent and was engaged as an organist successively at Hartford, Conn., Boston, and at Albany. He studied in Europe in 1863 and in 1872, was organist at the church of the Immaculate Conception, Boston, in 1876–1878 and occupied that position after 1883. In 1878–1883 he was organist at the Cincinnati Music Hall and professor of organ and composition at the Cincinnati College of Music. He was engaged as a teacher in the New England Conservatory of Music for several years but resigned in 1897. His compositions include *Grand Sonata; Tale of the Viking; Dream Pictures,* cantata; *Midnight,* cantata; a one-act opera in Italian, *Lenora* (1893); and numerous preludes and symphonies.

WHITING, Lilian, American author: b. Niagara Falls, N. Y., Oct. 3, 1859; d. April 30, 1942. She engaged in journalism in St. Louis, Mo., in 1876, in 1880–1890 was literary editor of the Boston *Traveler* and was editor of the Boston *Budget* in 1890–1893. Her published books are characterized by familiarity with occult subjects and a disposition to lead her readers unconsciously to recognize the genuineness of mysticism and spiritualistic teaching. They include *From Dreamland Sent,* verse; *The World Beautiful,* 3 vols. (1894, 1896, 1898); *Kate Field: a Record* (1899); *The World Beautiful in Books* (1901); *Boston Days* (1902); *The Outlook Beautiful* (1905); *Life Transfigured* (1910); *The Brownings—Their Life and Art* (1911); *Athens the Violet Crowned* (1913); *The Lure of London* (1914); *The Adventure Beautiful* (1917); *Canada the Spellbinder* (1917); *The Golden Road* (1918); *They Who Understand* (1919).

WHITING, William Henry Chase, American soldier: b. Mississippi about 1825; d. Governor's Island, New York Harbor, March 10, 1865. He was graduated first in his class at the United States Military Academy in 1845. He entered

the engineering corps and was engaged in military construction work, reaching the rank of captain in 1858. He resigned from the army Feb. 20, 1861 and entered the service of the Southern Confederacy. He was chief engineer of the Army of the Shenandoah under Gen. J. E. Johnston in June and July 1862, holding the rank of major; and was promoted brigadier general Aug. 27, 1861. He saw service at the first battle of Bull Run and at the Battle of West Point, Va. He was promoted major general in 1863, built Fort Fisher, N. C., and in 1864 was placed in command there. He was wounded and taken prisoner when Fort Fisher fell, Jan. 15, 1865, later dying from his wounds.

WHITING, city, Indiana, in Lake County; altitude 587 feet; on Lake Michigan; 17 miles southeast of Chicago; on the Pennsylvania, and the New York Central railroads, with freight service via several other lines. Its environment is industrial; its own products include oils, chemicals, roofing, steel, and soap. It has a public library, public and parochial schools, a community center, and a National Guard armory. Settled in 1852, it was incorporated as a town in 1895; as a city in 1903. It has mayor and council. Pop. (1950) 9,669.

WHITING, a name applied to several quite unrelated fishes probably in allusion to the noteworthy whiteness of their flesh, or, in some cases, of the skin of the lower parts. In the United States, and more especially in the South, several species of *Menticirrhus,* a genus of Sciaenidae, are known as whiting, but more commonly as kingfish (q.v.). The common whiting (*M. americanus*) reaches a length of about a foot; the body is elongated and slender with a high spinous dorsal and a long low soft dorsal fin, an undulate caudal fin, and is completely covered with ctenoid scales; the outer row of teeth of the upper jaw are enlarged and strong and the color silvery gray with faint oblique dusky bars. It is very common along sandy shores of the entire Gulf coast and on the Atlantic coast northward to about the mouth of Chesapeake Bay and southward to Brazil. Though remaining on these coasts throughout the year they are most plentiful in summer when they frequent the bays and estuaries, but prefer strong currents and the deeper waters. They feed upon crabs, shrimps and other crustaceans, and being vigorous biters and gamy fighters afford splendid angling. Great numbers are caught on lines for the market and the flesh is unusually firm, delicate and well-flavored. Spawning is said to occur in May. The surf whiting (*M. littoralis*) is so called because, unlike the last, it frequents shallow waters along sandy shores and is captured in large quantities by means of seines. The outer teeth of the upper jaw are not enlarged; the gill-rakers are better developed than in the common whiting; and the black tip of the caudal fin is another mark of distinction. The common northern kingfish (*M. saxatilis*) also extends into southern waters and is there confused with the above species under the name of whiting. It may be recognized by its dusky color and the distinct, dark bands which cross the sides obliquely. Other species occur on the Pacific Coast.

By the New England fisherman the name of whiting or silver hake is given to a common species of the cod family (Gadidae), the *Merluccius bilinearis* of American ichthyologists, though many European authorities fail to distinguish it from the Old World *M. vulgaris.* From the great majority of the cods the whiting is distinguished by the total absence of a chin barbel and by the peculiar excavated area of the top of the skull; the second dorsal and the anal fin are long and each divided nearly in two by a deep notch. The body is elongated and covered with small scales; the color grayish silvery white below. This whiting is common in waters of moderate depth along the shores of New England and somewhat northward, and extends southward in deep water to Virginia and even to the Bahamas. Unlike most of the Gadidae, which are essentially bottom feeders, it is an active, roving species, which comes to the surface to pursue and feed upon herring and other fishes. Sometimes large schools appear on our coasts and many are captured in purse seines and pound nets. Spawning takes place at the bottom on the edge of the continental slope. Owing to its comparatively small size and the softness of its flesh it is one of the least important economically of the family.

The European whiting (*M. vulgaris*) is scarcely distinguishable from the American, but has much smaller scales, fewer spines in the first dorsal fin and larger teeth. It frequents shallower water and is very abundant along the northern coasts of Europe. It makes its appearance in vast shoals, keeping at a short distance from the shore, and is taken by the line in great numbers. It is considered the most delicate and most wholesome of all the species of cod; but it does not attain a large size, usually not exceeding a foot in length and under two pounds in weight. The food of the adults consists chiefly of fishes and of the young of shrimps and other crustaceans. Spawning occurs in, and the young frequent, the shore waters. As long as the young feed chiefly on the bottom they retain a chin barbel, but as their habits change this degenerates and finally disappears. Other fishes sometimes called whiting are the hogfish, harvest fish and a whitefish.

WHITING, a preparation of white chalk from which the grosser impurities have been removed. It is extensively used in the arts, also for cleaning silver and making putty.

WHITINSVILLE, village, Massachusetts, in Worcester County, town of Northbridge (q.v.); 17 miles southeast of Worcester; altitude 302 feet. Products include mill machinery, textiles and paper. Pop. (1950) 5,662.

WHITLOCK, Brand, American diplomat: b. Urbana, Ohio, March 4, 1869; d. Cannes, France, May 24, 1934. He first engaged in journalism, then served as a clerk in the office of the Illinois secretary of state, after which he studied law and was admitted to the bar of Illinois in 1894 and to that of Ohio in 1897, then establishing himself in law practice at Toledo. He was elected mayor of Toledo in 1905 and served four successive terms, declining a fifth nomination. He succeeded in securing a new city charter providing for the initiative, referendum, recall and direct nominations. He was by this time a well-established magazine writer, producing both verse and prose, the latter dealing in the

main with politics and economics in an uncompromising fashion. He was appointed Minister to Belgium by President Wilson in 1913 and was in office at the outbreak of the European War. He was entrusted with the representation of seven of the warring nations, remaining at his post after the German invasion. His skill in dealing with the difficulties of the situation under the German occupation earned for him a worldwide reputation; and he won scarcely less praise for his handling of the Belgian relief work. The necessity for his leaving invaded Belgium when the United States declared war upon Germany in April 1917 was viewed with deep regret in Belgium. He refused to leave Brussels unless accompanied by the other Americans there, and crossed into Switzerland 4 April 1917. He later visited King Albert of Belgium at the battle front, and after the signing of the armistice in November 1918 he resumed his duties at Brussels. He returned to the United States for a visit in 1919, and while at home the country's representation in Belgium was raised to rank of an embassy. He was ambassador from 1919–22. He is author of 'The Thirteenth District' (1902); 'Her Infinite Variety' (1904); 'The Turn of the Balance' (1907); 'Abraham Lincoln' (1908); 'The Gold Brick' (1910); 'On the Enforcement of Law in Cities' (1910–13); 'Forty Years of It: An Autobiography' (1914); 'Memoirs of Belgium Under the German Occupation' (1918); 'Belgium: A Personal Narrative' (1919); 'J. Hardin and Son' (1923); 'La Fayette' (1929).

WHITLOCK, hwĭt'lŏk, Elizabeth Kemble, English actress, fifth child of Roger Kemble (q.v.): b. Warrington, Lancashire, 2 April 1761; d. 27 Feb. 1836. She first appeared at Drury Lane theatre in February 1783, as Portia. In 1785 she was married to Charles Edward Whitlock, a provincial manager and actor, and seven years later accompanied her husband to this country, where they performed for many years in the principal cities. Mrs. Whitlock became the most popular actress of the day in America, and in Philadelphia frequently performed before President Washington and other distinguished persons. She returned to England in 1807 with a competency and thenceforth retired from the stage. In personal appearance and voice she was said to have strongly resembled her sister, Mrs. Siddons.

WHITMAN, Charles Otis, American zoologist: b. Woodstock, Me., 14 Dec. 1842; d. 6 Dec. 1910. He was graduated from Bowdoin in 1868, studied at Leipzig, and in 1880–81 was professor of zoology at the Imperial University, Tokio, Japan. He was engaged in further studies at the Naples Zoological Station in 1882, and in 1883–85 was assistant in zoology at Harvard. He was director of the Allis Lake Laboratory, Milwaukee, in 1886–89, and in 1889–92 professor of zoology at Clark University, Worcester, Mass. He became director of the Marine Biological Laboratory at Woods Hole, Mass., upon its foundation in 1888, and from 1892 until his death was at the head of the department of zoology at the University of Chicago. He was elected to the National Academy of Sciences in 1895. He founded the *Journal of Morphology* in 1887, and after 1883 was editor of the microscopical department of the *American Naturalist*. He has made a specialty of the development of the vertebrates and of the structure and development of worms. His writings include 'Methods of Research in Microscopical Anatomy and Embryology' (1885); 'Biological Lectures' (1890–95); 'The Inadequacy of the Cell Theory of Development' (1893); 'Animal Behavior' (1898), etc.

WHITMAN, Charles Seymour, American lawyer: b. Hanover, Conn., 28 Aug. 1868. He studied at Amherst College and then studied law at New York University, and was admitted to the bar in 1894. In 1901 he was appointed assistant corporation counsel of New York City where his effective work won for him the post of city magistrate. In this capacity he founded the Night Court in that city for the immediate trial of all offenders arrested at night. In 1907 Governor Hughes appointed him a judge of the Court of Sessions, and in the following year deputy attorney-general in the investigation of election frauds in the northern part of the State. In 1909 he was elected district-attorney of New York City on a Fusion ticket. In this capacity he secured representation of the district-attorney's staff in the city magistrate's office, and was active in suppressing arson offenders. The noted Becker trial came up during his tenancy of office, and Whitman's mastery of the case was most effective in unearthing and reforming the relations between certain members of the New York City police and professional criminals. The handling of the Schmidt murder case, the prosecution of the poultry trust and of election frauds won for Mr. Whitman the highest commendation. He was renominated in 1913 and elected almost unanimously. In 1914 Whitman was elected to the governorship of New York State. His principal plank was the reformation of the State finances, which he proceeded to institute vigorously by a reorganization of State departments and a thorough investigation of the salaries of Civil Service employees. In 1916 he was elected chairman of the Republican National Convention, where he urged the nomination of Charles E. Hughes for President. In September of the same year he was re-elected to the governorship and established a precedent by sending to every enrolled voter a report of his first term as governor, containing also reports of the heads of other State departments. In connection with the European War, the governor ably supported the Federal administration in war policies and effectively mobilized the State's resources. He also inaugurated a State Constabulary, and a new State Guard to replace the National Guard on service in France. In 1918 he was defeated for re-election to the State Governorship by Alfred E. Smith, the Democratic candidate. He resumed the practice of law in New York in 1919.

WHITMAN, Frank Perkins, American physicist: b. Troy, N. Y., 29 July 1853; d. 15 June 1919. He was graduated at Brown University in 1874 and took his A.M. there in 1877, later studying at Johns Hopkins University. He was professor of physics at Rensselaer Polytechnic Institute, Troy, in 1880–86; and thereafter occupied that chair at Western Reserve University.

WHITMAN, Marcus, American missionary and pioneer: b. Rushville, N. Y., Sept. 4, 1802; d. near Walla Walla, Ore. (now Wash.), Nov. 29, 1847. He studied medicine, took his degree in New York State in 1832, and practised first in Canada and then in western New York. In 1834 he offered his services to the American Board of Commissioners for Foreign Missions, and in 1835 went with Samuel Parker to explore the region of the Oregon, but did not go beyond Green River. In 1836, having married, with his wife and three fellow missionaries he set out to work among the Indians of the upper Columbia. The party crossed the plains by wagon, being the first persons to reach the Pacific Coast by this means. On May 1st they reached the Columbia River, and located themselves near the site of the present Walla Walla, Wash. They were soon followed by a large number of emigrants, who settled in what was then known as Oregon, and now forms the States of Oregon, Washington and Idaho. At this time the Hudson Bay Company was using every possible means to secure this territory to the English. When this plan became evident to Whitman he decided to take every precaution to forestall it. The Ashburton Treaty was then before Congress, and was expected to settle the Oregon question. In 1842–43 Whitman traveled over 3,000 miles to the East on horseback, enduring all the hardships of a Western winter in the mountains, and according to the statement of H. H. Spalding, one of his missionary companions, he reached Washington (March 3, 1843) only to find that the treaty had been signed, but that the Oregon question had not been included. Whitman, as Spalding's version represents, at once went to work to show the government the value of the land it had deemed worthless, demonstrated to the people the fertility of the soil of Oregon, and the fact that it could be reached by wagon, and then returned at the head of a large body of emigrants. By his daring ride and earnest endeavors Whitman, in this view of the matter, won this great section for the United States and the results of his work were secured by the treaty of 1846. This claim has been a subject of controversy, some history students favoring that of Jason Lee (q.v.). Whatever the verdict on the political phase, there is no doubt that Whitman's ride (he reached Boston March 30, 1843) resulted in the reversal of the missionary board's purpose to discontinue the southern branch of the mission in which he was engaged; and his work and that of his companions has a historical relation to the American settlement of the Oregon country. Whitman, his wife, and 12 of their companions were massacred by the Cayuse Indians. Consult Nixon, 'Life of Marcus Whitman' (1895); Mowry, 'Marcus Whitman' (1901); and Bourne, 'Essays in Historical Criticism' (1901); Hulbert, A. B., and D. P., eds., 'Marcus Whitman, Crusader' (1936–38); and Marshall, W. J., 'The Acquisition of Oregon and the Long Suppressed Evidence about Marcus Whitman' (Seattle 1911). See Oregon; Oregon Question, The.

WHITMAN, Sarah Helen Power, American poet: b. Providence, R. I., 1803; d. there, June 27, 1878. She was married to John W. Whitman, a Boston lawyer, was once engaged to Edgar Allan Poe, afterward writing a defense of him entitled 'Edgar A. Poe and His Critics' (1860); contributed numerous critical articles and poems to periodicals, and was noted for her conversational powers. Her verse was in part collected in the volume 'Hours of Life, and Other Poems' (1853), and fully in the posthumous 'Poems' (1879). 'Fairy Ballads' and some other works were written with her sister, Anna M. Power. Her finest poem, 'A Still Day in Autumn,' has much melody and beauty of expression and retains an honored place in anthologies.

WHITMAN, Walt (originally Walter), American poet: b. West Hills, Long Island, N. Y., May 31, 1819; d. Camden, N. J., March 26, 1892. He was educated in the public schools of Brooklyn, and learned the printer's trade, after which he taught in country schools in Long Island. For a brief period he did editorial and reportorial work on newspapers, and in 1847–48 he made an extensive pedestrian tour as a workman through the United States and Canada, subsequently employing himself as a carpenter and builder. His first and chief work, 'Leaves of Grass,' was published by himself in New York in 1855. This thin volume of 94 pages was received, for the most part, with abuse, mainly because of its unconventional metrical style and the freedom with which the poet dealt with moral and social subjects. During the American Civil War, Whitman's brother was wounded on the battlefield, and the poet, who hastened to his aid, remained afterward as a volunteer army nurse at Washington and in Virginia for the years 1862–65. One result of this experience was the small volume 'Drum Taps' (1865), subsequently included with 'Leaves of Grass.' After the war he held a government clerkship in Washington, but the fatigue and mental strain of his labors in the hospitals brought about a severe attack of paralysis in 1873. He was recovering from this when the sudden death of his mother in his presence caused a serious relapse. From this time he resided at Camden, N. J., never securing robust health. During all these years Whitman wrote with the old vigor and freedom of rhythm, but with less of the early crudeness of expression. Though Whitman, like Carlyle and Browning, may be a dangerous and dangerously easy model for imitation, he undoubtedly worked out for himself a style of distinction as notable as theirs. This in itself is a title of fame, or at least a charm against oblivion, even though his literary style ran to extremes and vices. His evolved style was a rhythmic recitative or irregular chant, precursors of which may be found in the English translation of the Psalms and other Biblical poems, in Macpherson's 'Ossian,' and in the later poems of William Blake. These chants vary in movement and seem governed by laws rhythmic rather than metric, which (like the grammar of an unwritten tongue) have never been formulated even by the inventors themselves. They have a peculiar, wild, stirring charm, which is apt, for a time, to make regular verses seem tame and insipid. As to subject, Whitman set himself the Atlantean task of uplifting into the sphere or dominion of poetry the whole of modern life and man, omitting nothing, con-

cealing nothing. His thesis is that of St. Peter's vision: "There is nothing common or unclean." Hence the logical necessity with Whitman to include the treatment of subjects which in modern society are tabooed as obscene and unmentionable; hence, too, the accusations of indecency, so evident and pertinent from the accuser's point of view, but so futile and irrelevant from that of the accused. Whitman was an idealist who bound himself by a solemn vow to be a thorough-going realist; and his resolute and often successful endeavor to secure this union gave his work its exceptional artistic quality. He was a prince of impressionists in literature. But so hard and high was the task that he set himself, that it is no matter of surprise that he sometimes, if not often, fails, and from heights where he was approaching the sublime falls perilously near the ridiculous. This is the fate of all artists who strive for the highest things, that their failures—often only apparent—are more easily detected than their solid achievements; hence the contumely and ridicule that a Turner or a Wordsworth, Keats or Shelley suffers at the hands of a clever but uninitiated critic. So it was largely with Whitman; but it is better to approach him in the same spirit that he has shown toward man and nature, that of forever seeking for what was great and good, while outfacing steadily and bravely every stern and refractory reality. As the years roll on, Whitman's work is more highly esteemed. He had the true poetic fire, and was one of those who "talked with angels," and had glimpses of the life beyond. Several writers have contended that he was "illuminated" like Moses and Swedenborg.

Besides the two books already mentioned, he published *Drum-Taps* (1865); *Democratic Vistas* (1871); *Passage to India* (1871); *After All, Not to Create Only* (1871); *As Strong as a Bird on Pinions Free* (1872); *Memoranda During the War* (1875); *Two Rivulets* (1876); *Specimen Days and Collect* (1883); *November Boughs* (1888); *Sands at Seventy* (1888); and *Goodbye, My Fancy* (1891).

The *Conservator*, of Philadelphia, Penn., is the organ of Whitman study. Consult Burroughs, J., *Notes on Walt Whitman as Poet and Person* (New York 1867); Bucke, R. M., *Walt Whitman* (New York 1883); *The Complete Writings of Walt Whitman*, ed. by R. M. Bucke, T. B. Harned, and H. L. Traubel, 10 vols. (1902); Harned, Thomas B., ed., *Letters of Anne Gilchrist and Walt Whitman* (New York 1918); Phelps, W. L., *The Poetry of Walt Whitman* (New York 1924); Bailey, John C., *Walt Whitman* (New York 1926); Holloway, E., *Whitman, An Interpretation in Narrative* (New York 1926); Arvin, N., *Whitman* (New York 1938); Fausset, H. l'Anson, *Walt Whitman, Poet of Democracy* (New Haven 1942); Canby, H. S., *Walt Whitman, an American* (New York 1943).

WHITMAN, town, Massachusetts, in Plymouth County; altitude 76 feet; about 4 miles east east of Brockton, and 21 miles southeast of Boston; on the New York, New Haven and Hartford Railroad. The chief manufacturing establishments are concerned with shoes and findings, tacks and nails, steel shanks, electric appliances, braid, burial vaults, and shoe machinery.

Whitman has several churches, public schools, and a public library. It is the birthplace of Francis Cardinal Spellman. The town was originally a part of Abington, was settled about 1670, and was known as Little Comfort or South Abington. It was set off in 1875 and incorporated as South Abington. In 1886 the present name was adopted in honor of Augustus Whitman. The government is administered by annual town meetings. Pop. (1940) 7,759; (1950) 8,413.

WHITMAN COLLEGE, located at Walla Walla, Washington, was founded by Cushing Eells as a memorial to Marcus Whitman (q.v.); it was chartered in 1859 as Whitman Seminary, but was not open to students until 1866; in 1882 the courses were extended and the standard raised. A new charter was obtained in 1883 by which the name was changed to Whitman College.

The college is coeducational. In 1951–1952 there were 49 on its teaching staff, 699 students; the value of grounds, buildings, and equipment was $2,055,000; total endowment was $2,462,913.

The curriculum is administered in three divisions: social sciences, letters and arts, and basic sciences. The college confers the degree of bachelor of arts, and the degree of master of arts. The Conservatory of Music has its own fully equipped three-story building and offers extensive courses in theoretical and applied music. Whitman is a residence college and maintains dormitories in which all women and all freshman men whose homes are not in Walla Walla are required to live.

WHITMAN NATIONAL MONUMENT, Washington, located 6 miles west of Walla Walla. Established in 1940, it contains 45.8 acres. It was named in honor of Marcus Whitman to commemorate his devotion to the welfare and needs of the Indians.

WHITMER, hwĭt'mẽr, **David**, American Mormon leader: b. near Harrisburg, Pa., Jan. 7, 1805; d. Richmond, Mo., Jan. 25, 1888. He brought Joseph Smith (q.v.) to his father's farmhouse near Palmyra, N. Y., where the "Golden Plates" were translated in June 1829. After being baptized by Smith he was one of three men privileged to examine the "Golden Plates" to testify to their supernatural source yet material character. In 1834 he was president of the "High Council of Zion," organized by Smith to manage Mormon interests in Missouri, and was one of the leading men of the denomination. However, Smith excommunicated him in 1838. In 1867 Whitmer and his family revived the "Church of Christ," but had made only 150 proselytes at his death.

WHITMER, hwĭt'mẽr, **Thomas Carl**, American composer: b. Altoona, Pa., June 24, 1873. He was educated at Franklin and Marshall College, and studied music in Philadelphia, Pa., and New York, N. Y. From 1916 to 1932 he was organist of the Sixth Presbyterian Church, Pittsburgh, Pa. He was composer in residence at Pennsylvania College for Women, 1948–1949. He composed a series of six music-dramas, works for piano and stringed instruments, choral works and many organ pieces. He is the author of *The Way of My Mind* (1917); *The Way of My Heart and Mind* (1920); *Song for Free Men* (chorus for massed groups, 1940); *I Am the Resurrection* (anthem, 1942); *The Arm of God* (a church cantata, 1945); *I Walk by the Three Rivers* (1946).

WHITMIRE, town, South Carolina, in Newberry County, on the Enoree River, 22 miles east of Laurens. It has cotton mills, and is in an agricultural community. Pop. (1950) 3,006.

WHITNEY, hwĭt'nĭ, **Adeline Dutton Train**, American author: b. Boston, Mass., Sept. 15, 1824; d. Milton, Mass., March 21, 1906.

She was married to Seth D. Whitney of Milton, Mass., in 1843. Although a frequent contributor to different periodicals during her earlier years, her real literary career did not begin until 1859, and her best work was done in the two following decades. Her writings, which are chiefly for young people, are wholesome in tone and entertaining in style, and include, among many others, *Hitherto: A Story of Yesterdays* (1869); *Real Folks* (1871); *Sights and Insights* (1876); *Bonnyborough* (1885); *A Golden Gossip* (1890).

WHITNEY, Alexander Fell, American labor leader: b. Cedar Falls, Iowa, April 12, 1873; d. Cleveland, Ohio, July 16, 1949. As president of the Brotherhood of Railroad Trainmen, he was recognized as one of the most powerful union spokesmen in the United States. Militant and outspoken, he was one of the key figures in the railroad wage controversy of May 1946, precipitating a nationwide rail strike which paralyzed transportation from May 23 to May 26, 1946.

Leaving high school in Cherokee, Iowa at 15 years of age, Mr. Whitney began his career by selling newspapers and candy aboard trains of the Illinois Central Railroad running between Dubuque and Sioux City, Iowa. His self-assurance won the favor of a railroad superintendent who hired him as a brakeman, and from 1890 to 1901 he worked in this capacity for the Illinois Central and other railroads throughout the Midwestern states.

In 1896 he joined the G. E. Boynton Lodge 138 of the Brotherhood of Railroad Trainmen at Eagle Grove, Iowa. The almost religious fervor with which he advocated the principles of unionism caused his fellow workers to elect him chairman of the local lodge, a post which led him into a lifetime of service with the brotherhood, of which he became president in 1928. As chairman of the Railway Labor Executive Association, 1932–1934, he served as spokesman for 21 railway labor organizations. It was largely through his efforts that the Railway Retirement Act of 1935 and the Omnibus Transportation Act of 1940 became law.

WHITNEY, Anne, American sculptor: b. Watertown, Mass., Sept. 2, 1821; d. Boston, Jan. 23, 1915. For several years before beginning work as a sculptor she contributed verse of high quality to magazines and newspapers. Her poems were collected and published in one volume in 1859. She opened her first studio as a professional sculptor in Watertown in 1860. In 1872, after four years of study abroad, she established her studio in Boston. Among her works are the statue of Samuel Adams for the Capitol at Washington, a bronze replica of which stands in Adams Square, Boston; one of Lief Erikson in Boston (replica in Milwaukee, Wis.); the statue of Charles Sumner in Cambridge, Mass., and portrait busts of many notables.

WHITNEY, Asa, American inventor: b. Townsend, Mass., Dec. 1, 1791; d. Philadelphia, Pa., June 4, 1874. As a boy he worked in his father's blacksmith shop, then became a machinist, and later manufactured machinery in Vermont and at Brownsville, N. Y. In 1830 he was appointed master machinist of the Mohawk and Hudson railroad shops, and three years later became superintendent of the road. In 1839–1841 he was state canal commissioner of New York. He settled in Philadelphia in 1842 after forming a partnership with Matthias W. Baldwin for the building of locomotives. In May 1847 he obtained a patent for a cast iron car wheel with a corrugated center web, and a patent for his method of manufacturing it; and in April 1848 he obtained a patent for an improved process of annealing and cooling cast iron wheels. With these three patents he developed his own firm into the largest car wheel works in the country. He left $50,000 to the University of Pennsylvania for a chair of dynamic engineering.

WHITNEY, Asa, American merchant: b. North Groton, Conn., March 14, 1797; d. Washington, D.C., Sept. 17, 1872. He began his business career about 1817 as buyer for a New York drygoods merchant and traveled abroad extensively. In 1836 he formed his own firm, but failed in the panic of 1837. He went to China where he made another fortune in a little over a year, and upon his return to America worked tirelessly to get Congress to authorize the building of a transcontinental railroad in order to expand trade with the Orient. Before his death one railroad to the Pacific coast had been completed and three others were begun.

WHITNEY, Caspar, American editor: b. Boston, Mass., Sept. 2, 1864; d. Irvington-on-Hudson, N. Y., Jan. 18, 1929. After graduation from St. Matthew's College, Calif., he spent several years in hunting and exploration. In 1888 he became sports writer for *Harper's Weekly,* and in 1898 went to Cuba as war correspondent for *Harper's.* He was editor of *Outing Magazine,* 1900–1909; *Outdoor America,* 1909; *Recreation,* 1913. He was a war correspondent in Mexico in 1914, and was correspondent in Europe for the New York *Tribune* in 1917–1919. He was editor of the *American Sportsman's Library,* and was author of several books, including *Hawaiian America* (1899); *Jungle Trails and Jungle People* (1911); *What's the Matter with Mexico?* (1916); *The Critical Year* (1918).

WHITNEY, Eli, American inventor: b. Westboro, Mass., Dec. 8, 1765; d. New Haven, Conn., Jan. 8, 1825. He worked his way through Yale, and in 1792 went to Georgia as a teacher. Finding a patron in the widow of Gen. Nathanael Greene, of the Revolutionary army, he resided on her estate and studied law. Cotton culture in the South at this period was hampered by the slow and difficult work of separating the cotton from the seed by hand. Whitney set to work to remedy this by inventing a machine, and by April 1793 he had succeeded in building one that could turn out 50 pounds of cleaned cotton in a day. He formed a partnership with Phineas Miller in 1793 to patent and make cotton gins, and returned to New Haven to begin manufacturing them; but before he could obtain his patents a number of imitations of his gin had been put into operation. Lawsuits in defense of his rights carried off his profits and $50,000 voted him by the state of South Carolina. Not until 1807 did he receive a clear title to his patent, and in 1812 Congress refused its renewal. In 1798, however, he obtained a government contract for the manufacture of firearms, and was probably the first to introduce the system of interchangeable parts.

He established his factory at Whitneyville near New Haven, and made a fortune by this manufacture. See also COTTON GIN.

WHITNEY, Gertrude Vanderbilt, American sculptor: b. New York City, April 19, 1877; d. there, April 18, 1942. She was the daughter of Cornelius Vanderbilt (1843–1899), and in 1896 was married to Harry Payne Whitney, son of William C. Whitney (q.v.). She studied sculpture in New York and Paris, and executed many notable commissions such as the *Aztec Fountain* in the Pan American building, and the *Titanic Memorial,* both in Washington, D.C.; the *St. Nazaire War Memorial,* France; the *Columbus Memorial,* Palos, Spain. In 1931 she established the Whitney Museum of American Art in New York, which was consolidated with the Metropolitan Museum of Art in January 1943.

WHITNEY, Henry Howard, American soldier: b. Glen Hope, Pa., Dec. 25, 1866; d. Madison, N. J., April 3, 1949. He graduated from West Point in 1892. In 1898, under orders from the secretary of war, and disguised as an English sailor, he made a military reconnaissance of the island of Porto Rico and obtained information which enabled Gen. Nelson Miles to take the island. He served throughout the Spanish-American war as captain and assistant adjutant general on the staff of General Miles, and accompanied him on his world tour in 1902–1903. He served as chief of staff, District of Paris, 1918–1919, and was retired by his own request in 1920.

WHITNEY, SIR James Pliny, Canadian statesman: b. Williamsburg, Ontario, Can., Oct. 2, 1843; d. Toronto, Sept. 25, 1914. He was called to the bar of Ontario in 1876, and practiced law at Morrisburg. He was elected to the Ontario legislature in 1888, where he became the leader of the Conservative Opposition. From 1905 until his death he was prime minister of Ontario. He was knighted in 1908.

WHITNEY, Josiah Dwight, American geologist: b. Northampton, Mass., Nov. 23, 1819; d. Lake Sunapee, N. H., Aug. 19, 1896. He was the brother of William D. Whitney (q.v.) After graduating from Yale in 1839, he spent the years 1842–1847 in study in Europe, then, with J. W. Foster, explored the Lake Superior region. They published a synopsis of the explorations in 1849, and a report on the geology in 1850–1851. Whitney was appointed state chemist and professor at Iowa State University in 1855, and was made state geologist of California in 1860. He labored on the survey of that state until 1874, publishing his *Geological Survey of California,* 1864–1870. Mount Whitney, the highest peak of the Sierra Nevada, was named in his honor. In 1875 he was appointed to the chair of geology at Harvard. He was the author of *The Metallic Wealth of the United States* (1854); *Yosemite Guidebook* (1869); and other works on geology.

WHITNEY, William Collins, American public official: b. Conway, Mass., July 5, 1841; d. New York City, Feb. 2, 1904. He graduated from Yale in 1863, attended Harvard Law School in 1863–1864, and was admitted to the New York bar in 1865. He took an active part in the proceedings against the Tweed ring, and as corporation counsel of the city, 1875–1882, thoroughly reorganized the law department. As secretary of the navy in the Cabinet of Grover Cleveland from 1885 to 1889, he accomplished much in the development of plans for strengthening the naval service. He did effective work for the election of Cleveland as governor of New York in 1882, and as president in 1884, and again in 1892, when he was manager of the Democratic campaign.

Whitney declined to enter the Cabinet again, however, preferring to pursue his business career. One of his largest enterprises was the consolidation of the various street railway lines in New York City The Metropolitan Street Railway system was mainly organized by him, and he was a director in many corporations and societies. He was especially interested in the breeding and training of horses, and as the leader of the American turf he worked for its elevation to higher levels of sportsmanship. At the time of his death he was one of the largest landowners in the East, with holdings in several states, including a game preserve of 16,000 acres in the Adirondacks. While his main residence was in New York, he maintained others in his various estates, as well as a house in London. He left two sons, Harry Payne Whitney and Payne Whitney.

WHITNEY, William Dwight, American philologist: b. Northampton, Mass., Feb. 9, 1827; d. New Haven, Conn., June 9, 1894. He was the brother of Josiah D. Whitney (q.v.). After graduating from Williams College in 1845 he studied at Yale, 1849–1850, and then went to Germany, where he continued his philological and Sanskrit studies under Franz Bopp at Berlin and Rudolf von Roth at Tübingen. He was appointed professor of Sanskrit at Yale in 1854, and in 1870 professor of comparative philology, retaining both posts until his death. In 1856 he published, with Roth, an edition of the *Atharva-Veda Sanhita,* and in 1862 issued at New Haven an edition, with translation and notes, of the *Atharva-Veda Prâtiçâkhya.* His *Language and the Study of Language* (1867) was an admirable exposition of the main principles of comparative philology. His other published works include a number of language text books; an edition of the *Taittiriya-Prâtiçâkhya* (1872), for which he was awarded the Bopp medal of the Berlin Academy; *Oriental and Linguistic Studies* (1872); *The Life and Growth of Language* (1875); *A Sanskrit Grammar* (1879); *The Roots, Verb Forms, and Primary Derivatives of the Sanskrit Language* (1885), a supplement to the grammar. He was a contributor to Otto von Böhtlingk's and Roth's great Sanskrit Dictionary (1853–1875), and was editor in chief of *The Century Dictionary of the English Language* (1889–1891). He was elected a member of the American Oriental Society in 1850 and wrote more than half of the contents of volumes 6-12 of the *Journal* of that society. He was one of the founders and was first president (1869) of the American Philological Association. The 19th volume of the *Journal* of the American Oriental Society (1897) contains a complete bibliography of his works.

WHITNEY, Willis Rodney, American chemical engineer: b. Jamestown, N. Y., Aug. 22, 1868. He graduated from the Massachusetts Institute of Technology in 1890, and took his Ph.D. at the University of Leipzig in 1894. In 1904 he was appointed nonresident assistant professor of theoretical chemistry at the Massachusetts Institute of Technology and nonresident professor in

1908. He was director 1900–1928 of the research laboratory of the General Electric Company, Schenectady, N. Y., and after 1928 vice president in charge of research. The perfecting of metallic electric lamp filaments and the development of wrought tungsten are among the results of his research. He was president of the American Chemical Society in 1910, and received its Willard Gibbs Medal in 1916. He was appointed to the Naval Consulting Board in 1915 and to the advisory committee of the United States Bureau of Standards, 1925–1930. He translated M. Le Blanc's *Electrochemistry* in 1896, and has been the recipient of many academic and scientific honors.

WHITNEY, Mount, a peak of the Sierra Nevada, California, Tulare and Inyo Counties, in the southeastern part of the state; altitude 14,495 feet, the highest elevation in the United States outside of Alaska. The slope is precipitous on the east, rising abruptly for about 11,000 feet from Owens Valley. The peak was named for Josiah D. Whitney (q.v.), who first measured its height in 1864.

WHITNEYITE, a metallic mineral, containing 88.4 per cent of copper and 11.6 per cent of arsenic and having the formula Cu_9As. It is known only massive, its structure being very fine-granular. It is malleable, has a hardness of 3.5 and specific gravity of about 8.5. Its color is pale reddish-white, tarnishing quickly to a bronze or nearly black. It was regarded as a rare mineral until discovery of large quantities in the Mohawk mine, Michigan, where it proved a valuable ore of copper.

WHITON, James Morris, American clergyman: b. Boston, Mass., April 11, 1833; d. New York, N. Y., Jan. 25, 1920. He was educated at Yale, and was rector of the Hopkins Grammar School in New Haven, Conn. (1854–1864). Ordained to the Congregational ministry in 1865, he held pastorates at Lynn, Mass. (1865–1875); Newark, N. J. (1879–1885); New York City (1886–1891); Haworth, N. J. (1898–1901). After 1896 he was on the editorial staff of the *Outlook*. Among his published works are several school textbooks in Greek and Latin, several volumes of sermons preached in Great Britain (1887–1889), and a number of books on religious subjects.

WHITRIDGE, Frederick Wallingford, American lawyer: b. New Bedford, Mass., Aug. 8, 1852; d. New York City, Dec. 30, 1916. He graduated from Amherst College in 1874, from Columbia University Law School in 1878, and was admitted to the New York bar in 1879. He became president of several electric railway lines in New York and its suburbs. In 1888 he was lecturer on administrative law at Columbia University, and in 1888–1894 on constitutional and political history. In 1906 he was special United States ambassador to Spain to attend the coronation of King Alphonso XIII.

WHITSIDE, hwĭt'sīd, **Samuel Marmaduke,** American soldier: b. Toronto, Can., Jan. 9, 1839; d. Bethesda, Md., 1904. He entered the United States Army in 1858, served through the Civil War, was brevetted major in 1865, and made captain in 1866. For more than 25 years he fought in the Indian wars on the Western frontier, where he captured Big Foot and his 400 Sioux warriors in December 1890, and on the following day commanded his regiment in the Battle of Wounded Knee. He was promoted lieutenant colonel in 1895; was in command of the 5th United States Cavalry during the Spanish-American War; and was in command of the Department of Santiago and Puerto Principe, Cuba, 1900–1902. He retired from active service in 1902.

WHITSITT, hwĭt'sĭt, **William Heth,** American clergyman: b. Nashville, Tenn., Nov. 25, 1841; d. Richmond, Va., Jan. 20, 1911. He graduated from Union University, Murfreesboro, Tenn., in 1861, was ordained to the Baptist ministry in 1862, served in the Confederate Army, 1862–1865, and was pastor of Mill Creek Church, Nashville, 1865–1866. After further study in America and abroad he became professor of church history at Southern Baptist Theological Seminary, 1872–1895, and president of that institution, 1895–1899. From 1901 until his death he was professor of philosophy at Richmond College, Va. He published *Origin of the Disciples of Christ* (1888), *Genealogy of Jefferson Davis* (1908), and other works.

WHITSON, hwĭt's'n, **John Harvey,** American novelist: b. Seymour, Ind., Dec. 28, 1854; d. Rowley, Mass., May 2, 1936. He was ordained to the Baptist ministry in 1898, taught Bible history and literature at Ward-Belmont College, Nashville, Tenn. (1920–1923), and was head of the department of religious education at Hardin College in Missouri, after 1923. Among his novels were *Barbara, a Woman of the West* (1903); *The Rainbow Chasers* (1904); *Justin Wingate, Ranchman* (1905); *Filibusters* (1910); *Edgewood Enigma* (1912); *Wings of Mars* (1914); *Mystery of Greenacres* (1916).

WHITSTABLE, hwĭt'stà-b'l, urban district, England, Kent County, is located 6 miles north of Canterbury, on the south shore of Thames estuary, near the mouth of the Swale. It has noted oyster fisheries. As early as 1830 it was the terminus of a railway from Canterbury. Pop. (1951) 17,467.

WHITSUNDAY, the seventh Sunday after Easter; a religious festival in commemoration of the descent of the Holy Spirit on the day of Pentecost. The name was derived from the white garments worn on that day by candidates for ordination and children presented for baptism. The older name was Pentecost. See also Pentecost.

WHITTEMORE, hwĭt'ê-mōr, **Amos,** American inventor: b. Cambridge, Mass., April 19, 1759; d. West Cambridge (now Arlington), March 27, 1828. He worked for some years as a gunsmith, and about 1795 formed a copartnership with one of his brothers and several other persons for the manufacture of brushes for carding cotton and wool. He had not been long in this business before he invented a machine for puncturing the leather and setting the wires of the cards, a work previously performed by hand. The invention was patented in the United States in 1797. In 1799 Whittemore went to England to secure his rights there, but was unsuccessful. In the United States the patent was sold for $150,000; but afterward his brother Samuel Whittemore repurchased it, and carried on the business. Amos Whitte-

more devoted his last years to the invention of an orrery, in which every planet was to describe its own orbit, but did not live to complete it.

WHITTEMORE, Thomas, American clergyman: b. Boston, Mass., Jan. 1, 1800; d. Cambridge, March 21, 1861. He studied for the Universalist ministry under the Rev. Hosea Ballou, and in June 1821 became minister of a church at Milford, Mass. The next year he became minister of a church in Cambridgeport until 1833. In 1828, with Russell Streeter, he bought the semimonthly *Universalist Magazine* and published it as a weekly under the title *Trumpet and Universalist Magazine.* Streeter shortly sold his interest to Whittemore, who remained as editor for 33 years. He was also president of the Cambridge bank and of the Vermont and Massachusetts Railroad, and represented Cambridge repeatedly in the state legislature. He published *A History of Universalism* (1830; enlarged 1860), *Songs of Zion* (1836), *Life of Hosea Ballou* (1854–1855), and other works.

WHITTIER, hwĭt'ĭ-ẽr, **John Greenleaf,** American poet: b. Haverhill, Mass., Dec. 17, 1807; d. Hampton Falls, N. H., Sept. 7, 1892. He was a Quaker, and was called "the Quaker poet." In his boyhood he worked on the farm he later described in his poem, *Snowbound.* He received but little formal education, though he contrived by working at shoemaking and teaching to pay for two periods of six months at Haverhill Academy in 1827–1828. When the Newburyport *Free Press* accepted a poem from him in 1826, it led to a lifelong friendship with the editor, William Lloyd Garrison (q.v.).

Whittier's fame has become so firmly established as a poet that most people forget his long career as an editor and reformer. He edited the *American Manufacturer,* a weekly concerned chiefly with mechanics, the industries and agriculture, in Boston in 1829, and in the following year the Haverhill *Gazette.* During 1830–1832 he conducted the *New England Review,* which George Dennison Prentice had brought into some prominence, at Hartford, Conn. To this time belong his first independent publications, *Legends of New England* (1831), and *Moll Pitcher* (1832). In 1833 he issued *Justice and Expediency,* an antislavery pamphlet, and acted as a secretary of the antislavery convention at Philadelphia, and was a member of the committee which drafted the declaration of principles. He sat in the Massachusetts legislature in 1835, and in the following year sold his farm and removed to Amesbury, some eight miles northeast of Haverhill, where he chiefly resided for the rest of his life. In 1836 he became secretary of the Anti-Slavery Society, and in 1837 published *Poems Written During the Progress of the Abolition Cause in the United States.* With that cause he was now thoroughly identified. At Concord, N. H., he, with George Thompson (q.v.), was mobbed during the latter's lecturing tour.

Whittier edited the *Pennsylvania Freeman* in Philadelphia during 1838–1840, and in the first of these years his office was sacked and burned by a mob. In 1844–1845 he edited the *Middlesex Standard* in Lowell, Mass., and during 1847–1860 was corresponding editor of the *National Era,* a Washington paper, sometimes writing half a dozen columns weekly of general articles and reviews. He also contributed to the *Atlantic Monthly* from its foundation in 1857. His poem, *A Word for the Hour* (January 1861), shows that he shrank from the Civil War and was prepared to let the Southern states secede. He hailed the end of the war and of slavery with delight, and did his utmost to induce the North to welcome back the South in the most generous spirit.

Besides those mentioned above, Whittier's publications include the following: *Mogg Megone* (1836); *Poems* (1838); *Lays of My Home and Other Poems* (1843); *The Stranger in Lowell* (1845); *Supernaturalism in New England* (1847); *Leaves from Margaret Smith's Journal* (1849), an imaginative description of early New England, and *Old Portraits and Modern Sketches* (1850), all four collected from the *Era; Voices of Freedom* (1846); *Songs of Labor, and Other Poems* (1850); *The Chapel of the Hermits, and Other Poems* (1853); *Literary Recreations and Miscellanies,* also gathered from the *Era* (1854); *The Panorama, and Other Poems* (1856); *Home Ballads and Poems* (1860); *In War Time, and Other Poems* (1864); *National Lyrics* (1865); *Snowbound: a Winter Idyl* (1866); *The Tent on the Beach, and Other Poems* (1867); *Among the Hills, and Other Poems* (1869); *Miriam, and Other Poems* (1871); *The Pennsylvania Pilgrim, and Other Poems* (1872); *Hazel Blossoms* (1875); *Mabel Martin: a Harvest Idyl* (1875); *The Vision of Echard, and Other Poems* (1878); *The King's Missive, and Other Poems* (1881); *The Bay of Seven Islands, and Other Poems* (1883); *Saint Gregory's Guest, and Recent Poems* (1886), and *At Sundown* (1892), a posthumous volume. The Riverside edition of his works, both in prose and in verse, carefully revised and annotated by himself, appeared at Boston in 1888–1889. The most complete edition of the poems is the one-volume Cambridge edition (1895).

Whittier was long interested in politics, though his active participation largely ceased with the development of antislavery opinion in the North. His services to the cause of antislavery were important. He wrote numerous occasional poems celebrating or denouncing incidents and events of the conflict, the best known being the *Ichabod* verses, "the most powerful that he ever wrote," rebuking the defection of Daniel Webster from antislavery principles in the *Seventh of March* speech. Opposed to the Civil War, Whittier insisted, when it was begun, that slavery was the vital question, and during its progress contributed largely to the small quantity of valuable poetry that it evoked. Subsequently he devoted himself to presenting in narrative and ballad poem the legends, traditions and history of colonial America, particularly New England; to describing, as he did notably in *Snowbound,* rural scenes and conditions, many of which have passed into history, and to writing several hymns which appear in the collections of many denominations. His work has been criticized for its inequality and faulty rhymes, and also somewhat for its moralizing tendency. Much of his verse does reveal a certain want of compression and verbal selections, due principally to the fact that it was written with a readiness approaching improvisation. To object to his moralizing tendency is simply to object to the point of view of one who was originally and strongly, a reformer. His leading characteristics are a fine simplicity, a convincing quality and what Lowell styled as his "genial piety."

He was less cosmopolitan than Longfellow, but by many critics has been ranked as not greatly inferior to that poet.

Consult Pickard, S. T., *Life and Letters of John Greenleaf Whittier,* 2 vols. (1894); Pickard, S. T., *Whittier as Politician; illustrated by his Letters to Professor Elizur Wright, Jr.* (1900); and Pickard, S. T., *Whittier-Land* (1904); Albree, J., *Whittier Correspondence from the Oak Knoll Collections* (1911); Denervaud, M. V., *Whittier's Unknown Romance; Letters to Elizabeth Lloyd* (1922); Sparhawk, F. C., *Whittier at Close Range* (1925); Mordell, A., *Quaker Militant, John Greenleaf Whittier* (1933); Currier, T. F., *Elizabeth Lloyd and the Whittiers* (1939); Bennett, W., *Whittier, Bard of Freedom* (Chapel Hill, N. C., 1941); Rowntree, A., *Whittier: Crusader and Prophet* (London 1946).

WHITTIER, city, California, in Los Angeles County; altitude 246 feet; 14 miles southeast of Los Angeles; on the Southern Pacific, and the Union Pacific railroads. The surrounding country is predominantly agricultural, producing fruits, especially avocados, walnuts, oranges, and lemons. A residential suburb, Whittier has little mechanical industry, but there are some foundries and oil well supplies. The city is the seat of Whittier College, a non-sectarian, coeducational institution founded by the Society of Friends in 1901; it possesses the world's largest Quaker church. A colony of Friends established the city in 1887, naming it in honor of the poet John Greenleaf Whittier; it was incorporated in 1898. Pop. (1940) 16,115; (1950) 23,820.

WHITTINGHAM, hwĭt'ĭng-ăm, **Charles,** English printer: b. Caludon, Warwickshire, June 16, 1767; d. Chiswick, near London, Jan. 15, 1840. He served his printing apprenticeship at Coventry, and in 1789 he established his own printery in London. In 1809 he removed to Chiswick, at that period still outside London, and there, in 1811, he founded the Chiswick Press, which became distinguished for excellence and beauty of workmanship. He was one of the first to issue cheap reprints of the classics, and he pioneered in bringing out India-paper editions.

Soon after Whittingham took his nephew, Charles Whittingham (1795–1876), into partnership, in 1824, the Chiswick Press issued Washington Irving's *Knickerbocker's History of New York* (1824) and Pierce Egan's *Life of an Actor* (1825). The younger Whittingham began block-color printing in 1840, and in 1844 reintroduced William Caslon's old-style type. In 1852 the Chiswick Press was moved back to London, where it continued to print many fine books for the publisher William Pickering (1796–1854), including the "Aldine" edition of the English poets.

WHITTINGHAM, William Rollinson, American Protestant bishop: b. New York, N. Y., Dec. 2, 1805; d. Boston, Mass., Oct. 17, 1879. He was graduated at the General Theological Seminary, New York, in 1825, ordained deacon in 1827, and priest 1829, and was in charge of Saint Mark's Church, Orange, N. J., until 1831. He then became rector of Saint Luke's, New York, and in 1835 was professor of ecclesiastical history in the General Seminary, which position he held until his consecration as bishop of Maryland in 1840. The written evidence of his learning is preserved in the pages of various periodical publications, such as *The Churchman,* of which one time he was editor. During the Civil War, in opposition to many of the people in Maryland, he was unflinching in his advocacy of loyalty to the Federal government.

WHITTINGTON, hwĭt'ĭng-tŭn, **Richard,** English merchant and mayor of London: b. Pauntley, Gloucestershire, England, 1358?; d. London, England, March 1423. He became a mercer in London, a member of the common council in 1385 and 1387, subsequently alderman and sheriff, and mayor in 1397–1398, 1406–1407 and 1419–1420. He was very liberal in charitable gifts. The legend which represents him as making his fortune by sending a cat in an outgoing ship to Barbary, where it was sold for a large sum, and as returning to London, which he had just quitted on hearing Bow bells sounding what seemed to be

"Turn again, Whittington,
Lord Mayor of London."

is without foundation.

WHITTREDGE, hwĭt'rĭj, **Worthington,** American artist: b. Springfield, Ohio, May 22, 1820; d. Feb. 25, 1910. He studied art in Cincinnati, worked there as a portrait painter 1842–1849, later went to Europe and studied under Andreas Achenbach at Düsseldorf, also in Paris, Belgium, Holland and Rome, returning to the United States in 1859, to become noted as a landscape painter of the Hudson River school. Accompanying Gen. John Pope on his western tour of inspection in 1874, he sketched many Rocky Mountain views. He was elected a National Academician in 1861, and he was president of the Academy in 1875–1876.

His chief works include *House on the Hudson River* (1863, in the New York Public Library); *Old Hunting Ground* (1864); *View of the Rocky Mountains from the River Platte* (1868); *Trout Brook* (1875); *Camp Meeting* (1906, in the Metropolitan Museum). The best known of his early paintings is *The Poachers,* which is often reproduced as a lithograph.

WHITWORTH, hwĭt'wûrth, Sir **Joseph,** English mechanical engineer: b. Stockport, Dec. 21, 1803; d. Monte Carlo, Jan. 22, 1887. He worked as a mechanic in Manchester and London, discovered the method of making a truly plane surface, and in 1833 established himself as a tool-maker at Manchester. Between 1840 and 1850 he developed his measuring-machine, by means of which he elaborated his standard system of uniform measures and gauges which was found by engineers to be of great usefulness. One of his devices which proved to be of much immediate service was that of a uniform system of screw-threads. He made many experiments in connection with rifles, and, in 1857, perfected a hexagonal-barreled rifle of great range, accuracy and penetrative power, highly excelling the Enfield, then largely in use. It was not accepted at the time by the War Department, as being of a caliber too small for a military weapon; though in 1869 the War Office declared that a weapon of such caliber would appear to be the most suitable. He was equally successful in the building of cannon, but his rifled gun with a 250-pound shell and a six-mile range was rejected by the ordnance board in 1865, greatly to the detriment of British ordnance. His invention of compressed cast steel for ordnance was an important one, and came into general use. His works at Manchester were converted into a limited liability company in 1874, and in 1897 united with the Elswick works, established by Sir William Armstrong (q.v.). His fortune was devoted

to the endowment of 30 scholarships in mechanics and to the furthering of charitable and educational work. He was made a baronet in 1869.

WHITWORTH GUN. See ORDNANCE.

WHOLE FAMILY PROTECTION. See INSURANCE, FRATERNAL.

WHOOPER, the whooping swan. See SWAN.

WHOOPING COUGH, an infectious disease which most commonly attacks children, generally but once in their lives. It is characterized by a series of coughs ending in a long-drawn breath, during which a shrill whistling sound—the whoop—is produced. Several fits of coughing succeed one another until some phlegm or mucus is expelled. Vomiting not infrequently follows a fit of coughing. The first symptoms, usually five or six days after exposture to infection, are those of a common cold or sore throat; a difficulty of breathing and other slight febrile affections are succeeded by horseness, cough and difficulty of expectoration. After 10 to 14 days the cough becomes convulsive and is attended by the whoop, which is caused by the inspiration of air through the contracted cleft of the glottis. These spasms occur at uncertain intervals, but usually about every two hours, and between them the child returns to play, takes food with good appetite, and exhibits little sign of illness. In four or five weeks the disease reaches its height, after which the expectoration becomes loose and the fits of coughing gradually diminish in frequency and duration. This second stage may last from two to eight weeks and is succeeded by convalescence, the duration of which is variable. Whooping cough is seldom fatal to adults, but is most fatal in the first year of childhood. Bronchitis and pneumonia are the most serious complications. Patients should not come in contact with other children. Vaccines are said to have prophylactic as well as curative properties.

WHOOPING CRANE. See CRANE.

WHORTLE-BERRY. See VACCINIACEAE.

WHYDAH, whĭd'ŭ, a French West African seaport, known also as Ouidah (q.v.).

WHYDAH-BIRD, WHIDAH-BIRD, or **WIDOW-BIRD,** a weaver-bird (q.v.) of the West African subfamily *Viduinae;* in which the tail-feathers are greatly prolonged and modified. The paradise whydah-bird is brownish-black, the head, chin and throat being black and the neck encircled by a brown collar. The under parts are pale brown. The tail is long and the two central feathers are elongated and possess broad webs at the tip and a slender shaft, while the two next feathers are about 11 inches long and are broadly webbed. The other tail feathers are set vertically. This species attains a length of five or six inches, exclusive of the tail feathers. The nest is said to be ingeniously made of cotton fibres and to be divided into two compartments, in one of which the female sits on the eggs, but the other being occupied by the male bird. The shaft-tailed whydah-bird (*V. regia*) is colored a rusty red on the head and neck, the back of the head and crown being black. The average length of this species is eight or nine inches, and the four central feathers are elongated, but consist each of the bare shaft or quill only, a slight web existing at their tips.

WHYMPER, hwĭm'pĕr, **Edward,** English mountain climber, artist and author: b. London, April 27, 1840; d. Chamonix, France, Sept. 16, 1911. He was trained as a wood-engraver, and in 1860 he was sent by a London firm to make sketches of Alpine peaks. He ascended Mount Pelvoux, in the French Alps, in 1861, and three years later the Pointe des Écrins, his party being the first to accomplish the latter feat. In 1865, at his seventh attempt, he reached the summit of the Matterhorn, hitherto unscaled, but four of his party of seven lost their lives during the descent. In 1867 and 1872 he visited northern Greenland, where he discovered magnolia cones which gave evidence of a previous abundant vegetation there; his valuable collection of rare fossils, trees and shrubs was acquired by the British Museum. In 1879–80 he explored the Andes in Ecuador with the prime objectives of studying mountain-sickness and the effects of diminished pressure on the human body. During this journey he discovered the Andean glaciers, collected specimens of fossils, plants and animals, and, in 1880, was the first to reach the summit of Chimborazo, a feat which Friedrich Heinrich Alexander Humboldt (q.v.) attempted and failed to accomplish; he also ascended Cotopaxi, and was the first man to climb six other lofty peaks. In 1901–05 he made exploring tours of Canada, ascending mountains and making investigations in the Great Divide region of the Rockies. His books include: *Scrambles amongst the Alps in the Years 1860–69* (1871); *Travels amongst the Great Andes of the Equator* (1892); *Chamonix and Mont Blanc* (1896; 15th ed., 1910); *Zermatt and the Matterhorn* (1897; 14th ed., 1910).

WHYTE, Alexander, clergyman of the Free Church of Scotland: b. Kirriemuir, Forfarshire, Scotland, Jan. 13, 1837; d. London, Jan. 6, 1921. He was educated at the University of Aberdeen and at the New College, Edinburgh. He was assistant minister of Free Saint John's, Glasgow, 1866–70; assistant minister, 1870–73 and minister, 1873–1909 of Free Saint George's, Edinburgh. He was professor of New Testament Literature and also principal of New College, Edinburgh, from 1909 to 1918. He published *A Commentary on the Shorter Catechism* (1882); *Bunyan Characters* (4 series, 1893–1908); *Samuel Rutherford and some of his Correspondents* (1894); *Jacob Behmen; An Appreciation* (1894); *Lancelot Andrewes and His Private Devotions* (1895); *Four Temperaments* (1895; later ed. 1910); *Bible Characters,* 6 vols. (1896–1902); *Saint Teresa: an Appreciation* (1897, 1910); *Father John of the Greek Church* (1898); *Sir Thomas Browne: an Appreciation* (1898); *Characters and Characteristics of William Law* (1898); *Newman: an Appreciation* (1901); *Bishop Butler: an Appreciation* (1903); *The Apostle Paul* (1903); *Walk, Conversation, Character of Jesus Christ Our Lord* (1905); *Thomas Shepherd, Pilgrim Father and Founder of Harvard* (1909); *Thirteen Appreciations of Old Time Divines, Mystics, and Churchmen* (1914).

WHYTE-MELVILLE, hwĭt'mĕl'vĭl, **George John,** British novelist: b. Fifeshire, Scotland, June 19, 1821; d. Vale of Aylesbury

Berkshire, Dec. 5, 1878. He was educated at Eton, and at 18 joined the 93rd Highlanders, from which he transferred in 1846 into the Coldstream Guards. In 1849 he retired, but with outbreak of the Crimean War in 1854 he volunteered for service and was appointed major of Turkish irregular cavalry. The rest of his life was chiefly devoted to fox-hunting and the writing of novels of sporting and country-house life. Although an excellent horseman, he was killed by the fall of his horse while hunting. His sporting novels included *Captain Digby Grand* (1853), *Kate Coventry* (1856), *Tilbury Nogo* (1861), and *Black but Comely* (1879). *The Gladiators* (1863) was the best of several historical novels. His *Songs and Verses* (1869) contained some lyrics of considerable charm. Valuable notes on horsemanship are found in his *Riding Recollections* (1875).

WIARTON, lake port, Ontario, Canada, in Bruce County, on an inlet of Georgian Bay, 125 miles northwest of Toronto, served by the Canadian National Railway. Pop. (1951) 1,955.

WIBERT. See GUIBERT.

WIBORG, alternate name for the Russian seaport of Viipuri (q.v.) and for the Danish town of Viborg (q.v.).

WICHERN, vĭk'ĕrn, **Johann Hinrich,** German evangelical theologian: b. Hamburg, April 21, 1808; d. there, April 7, 1881. He studied theology at Göttingen and Berlin, and then, returning to his native town, gave himself up to endeavors to improve the condition of the poor and suffering. In the Rauhes Haus (founded Nov. 1, 1833) he established an institution for neglected children, with a training seminary for teachers connected with it, and similar institutions were shortly afterward formed throughout Germany. In 1856, he was appointed councilor of the Prussian Ministry of the Interior, and, in 1858, superintendent of all penal and reformatory institutions in the kingdom. His writings include *Die Innere Mission der Deutschen Evangelischen Kirche* (1849); *Die Behandlung der Verbrecher und Entlassenen Sträflinge* (1853); *Der Dienst der Frauen in der Kirche* (1858).

WICHITA, wĭch'ĭ-tô, **city,** Kansas, seat of Sedgwick County, situated at an elevation of 1,400 feet above sea level, on a broad plain in the south central part of the state at the junction of the Arkansas and Little Arkansas rivers; it lies 146 miles southwest of Topeka and 230 miles southwest of Kansas City, and is served by the Santa Fe, Rock Island, St. Louis-San Francisco, Midland Valley, and Missouri Pacific railroads. The city is the commercial and industrial center of a rich agricultural and oil and gas producing district. Leading agricultural products of the vicinity are wheat, cattle, and other livestock, dairy products, and poultry. Wichita is an important grain and livestock market and shipping center. It has an extensive wholesale and retail trade, railroad shops, and large-scale flour milling, meat packing, and oil refining concerns; manufactures include aircraft, stoves, furnaces, and household appliances, machinery, oil field equipment, refrigerator cars, building supplies, and dairy, food, and other products.

Besides a modern school system, educational facilities include the Municipal University of Wichita (q.v.), Friends University, Sacred Heart Junior College (Catholic) for women, a city library, an art museum, the Public Museum, the Wichita Art Association, daily newspapers, and the Pioneer Society of Sedgwick County, which maintains local history exhibits. The city has a number of parks, playgrounds, and recreation centers. In Riverside Park is the city zoo. Lawrence Stadium, built in 1934, provides seating accommodations for 6,000, while the Municipal Forum seats 4,800. Wichita is the scene of the annual Kansas National Livestock Show. The United States government maintains here a federal district court, a veterans' hospital, and other agencies.

History.—In 1864, a trading post was established at the juncture of the Arkansas and the Little Arkansas rivers by James R. Mead, with the assistance of Jesse Chisholm (q.v.). In the vicinity was a temporary Wichita Indian village. With the removal of the Wichita tribe to Oklahoma Territory (see OKLAHOMA) following the treaties of the United States with the Indians there in 1867, a white settlement soon grew up at the trading post. The trail followed by Chisholm on a trading expedition in 1865, later known as the Chisholm Trail, quickly became an important overland cattle route, and the settlement at Wichita, whose name is derived from the Wichita village, a stopping point for cattle drivers. Wichita was laid out in 1869, incorporated as a town in 1870, as a city of the third class in 1871, second class 1872, and first class 1886. In 1872, the Santa Fe Railway arrived, a United States land office was opened here, and the Wichita *Eagle* and Wichita *Beacon* were founded. Development of the rich agricultural lands and other natural resources of the vicinity, and of city commerce and industries brought prosperity to Wichita, whose population rose from 4,911 in 1880 to 23,853 by 1890. Since the turn of the century, the city has continued to make notable progress along many lines. It has the commission-manager type of government. Pop. (1940) 114,966; (1950) 168,279.

WICHITA, Municipal University of, a coeducational institution at Wichita, Kans. With assistance from the Boston Education Society, it was established in 1892 under the auspices of the Congregational Church. A collegiate department was formed in 1895, and the following year the name of the institution became Fairmount College. In 1926, the name was changed to Municipal University of Wichita. It offers courses in liberal arts, business administration, home economics, and public school music; and also offers pre-law, pre-medicine, pre-theology, and pre-engineering courses. In 1951–1952, it employed a teaching staff of 140 members and had a student enrollment of 3,700; the value of the plant was $2,600,861, and endowments totaled $91,812.

WICHITA FALLS, city, Texas, seat of Wichita County, at an altitude of 946 above sea level, on the Big Wichita River 120 miles west-northwest of Fort Worth. It is 12 miles from the Oklahoma state line, and is served by the Fort Worth and Denver City, the Missouri, Kansas and Texas, the Wichita Valley, and the Wichita Falls and Southern railroads. The city, which has an area of 10.83 square miles, is in a rich farming and stock-raising country, intensively de-

veloped by irrigation. Cotton, sorghums, wheat, oats, barley, alfalfa, vegetables, fruits (peaches, plums, prunes, grapes), melons, poultry, beef and dairy cattle, and sheep are produced here. Even more important for the city is its nearness to the principal developed oil fields of north central Texas: only 15 miles from the Burkburnett field, 11 miles from Iowa Park, and 26 miles from Electra. The Wichita Falls oil district includes ten north Texas counties. Much of the development here has been by independents, and the city is the headquarters of most of the operators. There are three refineries in the city, and five more within a 50-mile radius, with six pipe lines. Wichita Falls has oil-field supply houses, and is the jobbing and wholesale center for this rich north Texas and south Oklahoma district; manufactures include oil-field equipment and tanks. Other factory products include flour, glass fruit jars, gas engines, air-conditioning equipment, brick and tile, dried egg products, cheese and creamery products, cottonseed oil, ginned and compressed cotton, work clothing, boots and shoes, foundry and machine-shop products.

Among the city's outstanding features are the federal building, a county courthouse, a memorial auditorium (built in 1928), the Kemp Public Library (opened in 1918), the Coyote Stadium, Hardin Junior College, and the Academy of Mary Immaculata. Lake Wichita, five miles to the southwest, Diversion Reservoir, 34 miles distant, and Lake Kemp, 45 miles to the southwest, are fine for fishing, boating, and duck shooting. Twenty-one city parks have a total area of 436 acres; Weeks Park, 260 acres in extent, is the largest.

A favorite camping site in the 1850's was this land near the falls of the Big Wichita. A townsite in 1876, it was reached by the first railroad (the Fort Worth and Denver City) in 1882, becoming the county seat in 1883, was incorporated as a city in 1889. In 1886 the five-foot-high falls in the river were wrecked when a dam washed out. Irrigation began in 1900. The first oil well came in, in 1901. The Burkburnett boom began in 1919, and a second boom in oil came in 1937. By the charter of 1924 a city manager is chosen by a board of six aldermen. Pop. (1920) 40,079; (1930) 43,690; (1940) 45,112; (1950) 68,042.

WICHITA INDIANS, one of the southern tribes of the Caddoan linguistic stock of North American Indians; their traditional home was the Wichita Mountains of Oklahoma, near which their reservation now lies. In the first half of the 19th century their principal village was on the north fork of Red River, a short distance below the mouth of Elm Creek, in Oklahoma, but four centuries ago (in 1541) Coronado found them in Kansas, between the Arkansas and Kansas rivers, in what the Spaniards designated the province of Quivira (q.v.). The typical house of the Wichitas is the grass lodge; they were always agriculturists, and formerly practised tattooing, from which custom and from their resemblance to their congeners, the Pawnees, they are called by the French *Pani Piqués.* They are now under the Kiowa agency in Oklahoma, with their subtribes, the Tawakoni and Waco.

WICK, Frances Gertrude, American physicist: b. Butler, Pa., Oct. 2, 1875; d. Poughkeepsie, N. Y., June 15, 1941. After graduating at Wilson College, Chambersburg, Pa., she taught for six years at Butler High School. Following four years of study at Cornell University she spent two years teaching physics at Simmons College. In 1910, she joined the faculty of the department of physics at Vassar College, and she occupied several posts there before becoming professor in 1922; she was elected chairman of the department of physics in 1939. During several leaves of absence from Vassar, she did research work in the laboratories of Cornell and Harvard universities, the laboratory of the General Electric Company, Cambridge University, in England, and the Institute for Radium Research, at Vienna. She achieved an international reputation for her work in the field of luminescence or cold light. Many articles by her in this field were published in the *Physical Review,* the *Journal* of the Optical Society of America, and the *Proceedings* of the National Academy of Arts and Sciences.

WICK, seaport and county town, Scotland, in Caithness, at the mouth of Wick River, which empties into Wick Bay, an inlet of the North Sea; it is situated 327 miles north of Edinburgh. Wick is the center of the Scottish herring fishery and kindred industries. An extensive breakwater gives protection to the two harbors. Pop. (1951) 7,161.

WICKARD, wĭk'ĕrd, **Claude Raymond,** American administrator: b. near Camden, Carroll County, Ind., Feb. 28, 1893. He graduated at Purdue University with a B.S. degree in agriculture in 1915, and for several years thereafter farmed his own large acreage in the vicinity of Camden. In 1933, he resigned his seat in the Indiana state senate and relinquished many local activities in order to go to Washington, D.C., to join the staff of the United States Department of Agriculture. At first assistant chief of the corn and hogs section of the Agricultural Adjustment Administration, in February 1940 he became undersecretary of agriculture. In August 1940, he succeeded Henry Agard Wallace (q.v.) as President Franklin D. Roosevelt's secretary of agriculture; in addition to the duties of this post, during World War II he was also administrator of food production and distribution. When President Harry S. Truman reorganized his Cabinet in May 1945, Wickard resigned the secretaryship of agriculture, and the following July he was appointed head of the Rural Electrification Administration.

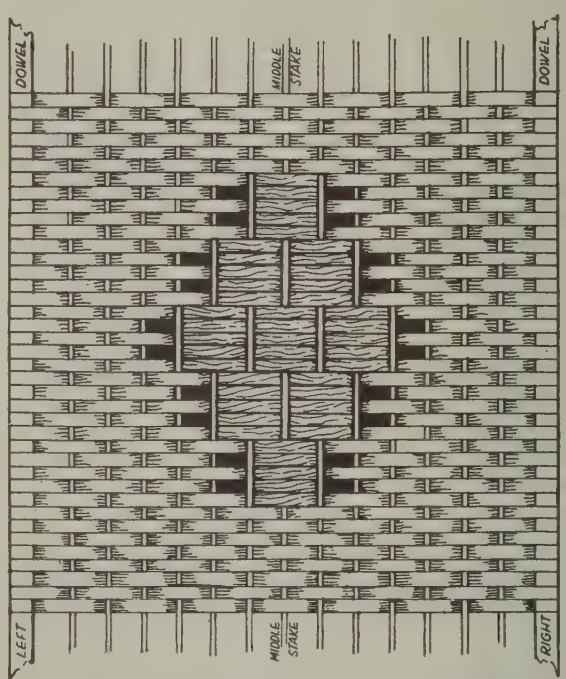
WICKER WEAVING AND PRODUCTS. The predecessor of all arts, the most universal art and the least changing art in the realms of history is wicker weaving. True, there have been changes in the commodities used for weaving and changes in the articles made by weaving, but the actual method of weaving wicker strands has passed down from the very earliest days of mankind with marked uniformity. Weaving in its general sense—including that of textiles as well as wicker—is considered by historians and Biblical students as the oldest of arts. Just when it was born and by whom created is impossible to say. Some Biblical students contend that Eve, following her great sin, wove a skirt of twigs and leaves through an endowed art. Other equally studious students assert that

Eve and her fellow Bib'ical personages learned the art of weaving by viewing the interlacing growths of tree limbs and noting the protection resulting therefrom. Still more assert that the art became known by persons through watching and adopting methods used by birds in weaving their nests, or spiders and other insects in weaving their webs. Whatever caused human intelligence to grasp the art of weaving may never be known, but that it is the earliest art is taken as an established or accepted fact. Actual Biblical evidences showing an early knowledge of weaving are found in Exodus 28:32, where it relates that bindings were made of woven work. The same book, 39:22, says that robes were made by weaving. Exodus 2:2 tells of an ark (basket) being woven of papyrus reed and Moses set adrift in it on the river Nile. Biblical commentaries also add that boats, sails, mats and ropes were made by weaving. There are other Bible references to weaving, thus indicating that the art, so far as wickerwork is concerned, was well known in those days. Historians, here and there, speak further of wicker weaving although they do not specifically use the word "wicker." The word has long been understood, however, as perfectly proper in classifying all materials used in the weaving of furniture, baskets and baby carriages. Modern dictionaries define "wicker" as (1) "a pliant young shoot or rod; twig; osier; withe; as, a willow wicker; (2) ware made of wickerwork; (3) a wike; mark." "Wickerwork" is defined as "a fabric or texture, as a basket, of woven or platted osiers, withes or twigs; basket work, as a chair of wickerwork." Since the accepted meaning is so broad it is quite easy to trace wicker weaving down through the many ages to the present day although there is a surprising lack of written information on the entire subject. It is known that practically every race of human beings has been familiar with the art of wicker weaving, for in the history of all races there are references to woven bags, baskets, roofs, floors, and furniture. And yet with all this great age and universal use we find that wicker weaving (not textile weaving) has remained as it began—a slow hand vocation in which the strands have been woven about a frame. That is, the development remained unchanged until 1916, when Marshall B. Lloyd of Menominee, Mich., invented and put into practical use a new method for weaving wicker and a loom which weaves the strands into shapes desired.

Commodities.—Biblical data shows that the first wicker weaving was done by using natural leaves and twigs, interlacing them at right angles in just the same manner as modern hand weavers work with their more modern commodities. Then came heavier pieces of wood as is indicated in II Kings 23:7, which says, "women weave hangings from the grove." Whether this means limbs of trees, or vines hanging from trees, is unknown although the latter is the accepted version. Exodus 2:2 specifically states the ark (basket) of Moses was woven of papyrus reed just as were boats, sails and other articles. Medieval days find the willow branch popular for wicker weaving. It has remained so to the present day although the scarcity of it and the growing demand for woven work in general has made it necessary, as well as wise, for manufacturers to turn to other forms of wicker. Rattan has been most generally used in making wicker articles during recent years. It is a vine growing in India, China, South Africa and elsewhere in the Orient. It was first used as ballast for vessels returning from the Orient. When the rattan reached America it was burned as firewood or waste. It was discovered, during the days of the hoopskirt, that rattan would lend itself to the manufacture of hoops. This led to its becoming prominent in the manufacture of woven furniture and bodies for baby carriages. Rattan is usually known as reed when used for these purposes. The rattan vine is harvested by natives, then cured and classified as to size and texture. The bark is removed and treated, thus becoming "cane" and used most extensively as seats for chairs, davenports and the like. The wood part of the rattan vine inside the bark is also treated, and the finished product is known as "reed." While being woven, reed is kept in water so as to make it pliable. If it is not soaked the reed will not bend without breaking, and despite its extensive use the article gives only limited satisfaction owing to its brittleness. The most recent form of wicker is a fiber made from paper. Just whether it should be classified as a textile or wicker has not been established. It is manufactured much like a textile (see TEXTILE INDUSTRY) and is used very extensively as a wicker and a textile. It, however, quite naturally fits in under the wicker classification. The lack of willow and the dissatisfaction over reed has long caused baby carriage, furniture and basket makers to seek a new article. World War I, perhaps, had most to do with the discovery of paper and its adaptability to textile and wickerwork. During the war there arose an amazing lack of clothing, bags, cordage, and other articles of this nature. The strength of paper, which has long been used in railway car wheels, its pliability and other abilities to be treated chemically, so that when completed it can resist weather conditions without injury, evidently turned the human mind to paper. Tests have proven that a piece of twisted paper gauging $\frac{1}{1000}$ of an inch is stronger than any known steel of the same weight. Experiments have proven that certain hard or tightly-twisted paper $\frac{80}{1000}$ of an inch in diameter will not break unless the tension is more than 50 pounds, while the same thickness of reed will not stand a strain of 13 pounds. G. L. Brownell made the first real paper-twine machinery Dec. 17, 1895. Gradually the use of twisted paper as a textile became general in the manufacture of clothing, bags, cordage, belts, caps, hats, braces and leather substitutes. Then it spread to wickerwork, where it finds its most adaptable place. In recent years we have made tremendous strides in the paper trade. Special machinery for making textile and wicker fiber from reels of paper are now manufactured. The Scandinavian countries are producing large amounts of paper fibers, while the British government has for some time been interested and busy in the manufacture of paper fiber articles. The evenness of strength, freedom from odor, absence of loose ends, flexibility, elasticity, strength, as well as weather and water-proofing qualities make paper fiber today the most important strand in the manufacture of wicker woven articles. In addition to the above advantages it is much cheaper and more abundant than any other form of wicker. The ability of paper to permit itself to be manufactured into wicker fiber, either alone or with cotton, wool and even wire centers, and its ability to accept modern chemical and other treatments for purposes of strength and elasticity, adds to its importance and

growing popularity. All other forms of wicker are used in a more or less natural state and do not require or lend themselves to chemical or other advanced treatments of mankind. Wicker fiber, however, overcomes these objections. Since all other wickers except wicker fiber are used practically in their natural state it is necessary to weave the strands in large sizes. This does not make possible for them the beautiful finishes of the wicker-fiber articles. Owing to the smallness of the best hard wicker fibers, the article manufactured usually has from two to four times as many feet of fabric as the natural wicker woven articles, therefore making the wicker fiber article stronger. The shortness of natural wickers, like willow and reed, make it necessary for ends to occur frequently in furniture, baskets or baby carriage bodies. Wicker fiber can be made in endless strands, thus doing away with unsightly ends. Wicker fiber originates, like paper, from the forest with fir and pine proving the most satisfactory wood, although almost any kind can be used. After the trees have been cut and the logs sent to the paper mills a pulp is formed. (See PAPER.) This pulp becomes paper and is cut into ribbons of various widths. These reels of paper ribbon are run through baths of resin glue for purposes of preservation and toughening. Then the ribbons enter twisting devices running 5,000 to 20,000 revolutions per minute. Sometimes wire centers are used but usually pure paper fiber is manufactured. The twisted paper ribbon is dried and is then ready for weaving. After being woven the shaped article is dried and painted from two to four times with enamel or shellac. These various treatments make the fiber absolutely impervious to water, sunshine and other weather conditions.

Methods of Weaving.—Hand weaving must have been the only method used in Biblical days, so far as wicker weaving is concerned, for there is no mention of any machine being used. The Biblical method consisted of weaving two strands at right angles to each other, considerably or exactly like textile weaving. (See TEXTILE INDUSTRY.) When wicker was to be woven a frame was made and the upright strands or weft attached to it. Then the warp was interlaced through the weft. This method has been handed down through all ages and through all peoples until today. Many men have tried to change the method of the biblical days but failed. More tried to use the same method and weave wicker on machines like textiles are woven. But all of these inventors, save one, were doomed to failure. Marshall B. Lloyd of Menominee, Mich., spanned the gap of centuries by changing the method of weaving before trying to make a machine loom which would do the weaving. Instead of attaching either the weft or warp to the frame of the article desired, he found a way of weaving the wicker independent of the frame and then attaching the wickerwork to the frame. Any of the modern wickers lend themselves to his method. Later he produced a machine known as the Lloyd Loom, which weaves the wicker 30 times faster than the most expert hand weaver can, and with far greater superiority. The loom also lends itself to weaving any kind of wicker strand. The Lloyd Loom requires that the weft be attached to a drum. The warp is fed through a stationary shuttle after being made more or less continuous by connecting the ends of various pieces of wicker or by making continuous wicker fiber. The average baby carriage body of years ago of endless wicker fiber was usually woven on the loom in 18 minutes, while a hand weaver required an entire day of nine working hours to accomplish the same results. And even then the work would not be nearly as smooth and beautiful. This is due to mechanical exactness in weaving as compared with human lack of exactness, as is very evident when the old homespun textiles are compared with modern machine-woven products. The weaving of cane for chair seats, etc., has been in vogue for many years. This kind of weaving is called flat weaving and requires no shaping as does furniture, baby carriages and baskets. Hence, the early solution of its mechanical weaving problems.



From *Fiber Furniture Weaving* by Emil Gandre; Bruce Publishing Co.

A diamond weave.

Wicker-Woven Baby Carriages.—The development of the baby carriage has been slow. The first baby carriages were merely baskets like that in which Moses was found. The American Indian mother with her papoose strapped on her back, either in skins or in woven articles, according to weather conditions, originated another form of the baby carriage. While there is no authentic data to show the development of the baby carriage, it is taken for granted that when man put wheels under a sledge, thus making a wagon, he conceived the idea which led to the modern wagon, baby carriage, train, and even the automobile. The first form of a baby carriage was a basket with a wheel on either side. Then came the elaborate chariotlike carriage, but still with only two wheels. The latter came into prominence in the 18th century. Early in the 19th century the baby carriage took the shape of the average toy express wagon with four solid wood wheels. Then came the collapsible carts which could be folded up into a small article. Wicker-woven carriages regained prominence in the 20th century, and were popular until 1935. Most of them were made of beautifully woven bodies or baskets. The finer the strand, the more even the weaving, and the greater the

cost to the ultimate purchaser. The bodies were set on steel springs which were either air or oil tempered, the latter producing more resiliency and solidity. Four wheels, two on either side, made of wood or wire and with rubber tires, a woven hood or top, a storm shield, smooth and soft upholstering, and wheel brakes complete the carriage.

Wicker-Woven Baskets. — These articles have been made ever since Biblical days, as shown in the above Bible references. There has been little advancement in the art. The usual wickers described above have been and are being used.

Wicker-Woven Furniture.—The Bible gives very little information on what sort of furniture was used at that time. It is said that the early Egyptians wove bedsteads of wickerwork, but what the make-up of the wicker was is not known. In 1650 a few chairs were made of wicker, while in 1711 wicker and cane chairs seem to have secured considerable general usage. In the 16th century the Hollanders made heavy wooden chairs and used woven cane or rush seats. The 19th century found chairs made of wicker willow and wicker reed. Tables, davenports, desks and bedroom furniture later were made of various kinds of wicker. The high cost of weaving, great waste of material, numerous short unsightly ends, combined with the lack of wearing and weather-proofing qualities kept the quantity of wicker-woven furniture to a very low ebb when compared with the vast volume of furniture made and used in the world.

GEORGE W. ROWELL, JR.

WICKERSHAM, George Woodward, American Cabinet officer and lawyer: b. Pittsburgh, Pa., Sept. 19, 1858; d. Jan. 25, 1936. He studied at Lehigh University and took his degree in law at the University of Pennsylvania in 1881. He first engaged in practice in Philadelphia, but after 1882 he practiced in New York. He was for many years a member of the law firm of Strong and Cadwalader; was counsel for the companies reorganizing the Chicago traction lines; for the Interborough Rapid Transit Company in the construction of the New York subway; and for the builders of the Pennsylvania tunnels in New York. He was connected with the reorganization of the Mexican railway system; and had a wide experience in railway litigation in the United States. He was attorney general of the United States during the Taft administration and handled successfully the anti-trust litigation, especially the cases against the Standard Oil Company and the Tobacco Trust. He was in 1924 American member of the Committee on Progressive Codification of International Law under the League of Nations; in 1929 President Hoover appointed him chairman of the National Commission on Law Observance and Law Enforcement, popularly known as the Wickersham Commission.

During a two-year period the commission delved deeply into the twin problems of observance and enforcement. One of its major conclusions was that the machinery for criminal law enforcement in the United States was entirely inadequate, and that the annual cost of crime amounted to the staggering total of $1,000,000,000. It was, however, the 80,000-word report on prohibition, released Jan. 13, 1930, that attracted widest attention. A majority of the commission disapproved the "noble experiment"; but the chairman and three colleagues favored further trial of the provisions of the Eighteenth Amendment and the national prohibition act. Less than two years later Mr. Wickersham conceded that prohibition had been a failure and urged that it be replaced by regulation of the sale of alcoholic beverages.

After 1932 he was president of the International Arbitral Tribunal until his death. He published a volume of essays and addresses, *Changing Order* (1914), and *Spring in Morocco* (1923).

WICKFORD, village, Rhode Island, in the township of North Kingston, Washington County; on Narragansett Bay, about eight miles northeast of Kingston. Founded in 1709 when Lodowick Updike, a real estate developer, began selling lots, its first house was probably erected in 1711. Wickford prides itself on possessing more 18th century houses than any other village of its size in New England; no less than 20, built between 1728 and 1804, are on its short Main Street. They include the gambrel-roofed Stephen Cooper House (1728), Immanual Case House (1786), and Ye Old Narragansett Bank House (1768), once used as a bakery, then as a bank, but residential since 1853. Rhode Island's first academy, Washington Academy, was established here in 1800. The South County Barn Museum has a fine collection of ancient implements used by farmers, mechanics, and housewives. Pop. (1950) 2,437.

WICKHAM, Edward Charles, English educator and dean of Lincoln: b. Hammersmith, London, Dec. 7, 1834; d. Sierre, Switzerland, Aug. 18, 1910. He received his early education at a private school in Hammersmith kept by his father, and at 13 entered Winchester College. Succeeding to a fellowship at New College, Oxford (William of Wykeham's other foundation), he began his undergraduate career at 17, won the chancellor's prize for Latin verse in 1856, and the Latin essay in 1857. Graduating B.A. the latter year, he was ordained deacon. Ordained priest in 1858, he taught at Winchester two years, then, having accepted a tutorship, returned to Oxford. He was one of the leaders in the reforms of New College which opened it to scholars and commoners who had not been educated at Winchester. He also helped to amend the statutes so that tutors and other college officials could retain fellowships after marriage. With a Balliol friend he initiated the system of intercollegiate lectures. In September 1873, he succeeded Edward White Benson as headmaster of Wellington College, and two months later was married to Agnes, eldest daughter of William Ewart Gladstone, the prime minister. Resigning his post in 1893, he was appointed dean of Lincoln Cathedral in January 1894. Devoted to the liberal principles of his famous father-in-law, he worked to improve the system of primary and secondary education in his diocese. His works include *Horace* (vol. 1, 1874; vol. 2, 1893); *Notes and Questions on the Church Catechism* (1892); *The Prayer-Book* (1895).

WICKHAM, William of. See WILLIAM OF WYKEHAM.

WICKING, *in curling,* an ingenious master stroke by which a stone is sent in an oblique

direction so as to hit the winner's stone and drive it from the tee, the former often replacing the latter and so becoming the winner in turn; also called "inringing."

WICKLOW, Irish Free State, a maritime county of Leinster Province, on the Irish Sea, with an area of 782 square miles. Chief town, Wicklow. The county generally is mountainous, but has fertile lowlands where oats and potatoes are cultivated, and much pasture land devoted to stock-raising. Iron and lead are mined, and a little copper. Pop. about 57,600.

WICLIF, wĭk'lĭf, **WYCLIFFE, WYCLIF, WICLIFFE,** or **WICKLIFFE, John,** English reformer: b. Spreswell, Yorkshire, probably about 1330; d. Lutterworth, 31 Dec. 1384. He studied at Balliol College, Oxford, of which he became master between 1356 and 1361, in which later year he was appointed by his college to the living of Fillingham, in Lincolnshire. About the same time the Pope bestowed upon him a prebend in the collegiate church of Westbury-on-Trym, near Bristol, in which he was confirmed by the king. In 1368 he gave up Fillingham and accepted the living of Ludgershall, in Buckinghamshire, and four years later qualified as doctor of theology. He was presented by the Crown in 1374 to the benefice of Lutterworth, in the south of Leicestershire, which he held till his death. A Latin tract 'Determinatio quædam Magistri Johnannis Wyclyff de Dominio contra unum Monachum,' has been regarded as belonging to the controversy raised by the refusal of the Parliament of 1366 to pay a tribute demanded by the Pope Urban V, in virtue of the homage paid by King John to Innocent III, but some authorities refer it to a date about 10 years later, when similar circumstances arose. At the time of writing the tract, Wiclif was regarded as royal chaplain, for he calls himself *peculiaris regis clericus,* and in 1374 was named second on a commission which went to Bruges to try to settle disputes concerning ecclesiastical jurisdiction with the representatives of the Pope Gregory XI. He had shortly before been appointed a canon of Lincoln, but never actually obtained a prebend in that cathedral. The development of his views on the relation between the ecclesiastical hierarchy and the secular authorities brought him into close association with John of Gaunt, duke of Lancaster, and his party, and in 1377 the anti-Lancastrians sought to strike at their political opponents through Wiclif. He was summoned in that year before Archbishop Sudbury and his suffragans at Saint Paul's, and attended, accompanied by Lancaster, Lord Percy, and other powerful Lancastrians. A violent altercation between the duke and William Courtenay, bishop of London, caused the break-up of the meeting, and the infuriated populace plundered Gaunt's palace and attacked Percy's house. Soon afterward Pope Gregory sent several bulls to the University of Oxford, the archbishop of Canterbury, and the bishop of London, in which he accused Wiclif of teaching the condemned doctrines of Marsilius of Padua and John of Jandun, and ordered him to be arrested and examined. The parties were reluctant to move in view of Wiclif's great popularity and influence, and even after the bulls had arrived he was consulted by the government as to whether they might legally prevent money from going abroad to absentee holders of benefices. He eventually appeared before the prelates at Lambeth in 1378, but the king's mother sent a message forbidding them to interfere with him, and a popular demonstration in his favor put an end to the proceedings. In the Gloucester Parliament of 1378 he made a defense of John of Gaunt, who had grossly violated the Westminster right of sanctuary.

This year, 1378, was an important date in Wiclif's religious career. While continuing to inveigh against certain abuses, he began to question the whole basis of sacerdotalism and its authority, and by 1381 had attained to a substantially Lutheran position in regard to transsubstantiation and the mass. About this time also he commenced his appeal to the common people and presented religion as a popular force rather than a dogmatic system or an organized institution. This appeal assumed two forms, the sending out of his "poor preachers" and the translation of the Bible from the Vulgate into the English of his day. His itinerant evangelists spread his doctrines throughout the land and soon made the Lollard movement one of great strength and importance. In his translation of the Bible he had the assistance of Nicholas Hereford, who was responsible for most of the Old Testament, and the whole work was revised by his assistant, John Purvey, who finished it soon after Wiclif's death. Wiclif's views on the eucharist were promptly condemned at Oxford and forbidden to be taught there, and in 1382 Courtenay, archbishop of Canterbury, summoned a council in the Blackfriars' convent hall, at which Wiclif's teaching was condemned and some of his followers excommunicated. This council known as the "earthquake council" because a violent earthquake occurred during the meeting, ordered the Carmelite, Dr. Stokes, to publish the condemnation at Oxford. The chancellor of Oxford University at that time, Robert Rygge, was a supporter of Wiclif and evaded the duty of carrying out the council's mandate until absolutely compelled to do so. Wiclif himself remained untouched, but he retired to Lutterworth, where he occupied himself in preaching and writing. It is said that Urban VI summoned him to Rome in 1384, but this is doubtful. He had a paralytic stroke in 1382 or 1383, and again in 1384, from which he died. He was buried at Lutterworth, but in 1428, in accordance with a decree of the council of Constance in 1415, his body was exhumed and burned, and his ashes thrown into the river Swift.

Of the 24 Wiclifite propositions condemned by the earthquake council, 10 were described as heretical and 14 as erroneous. The most important of the 10 were: that transsubstantiation is philosophically false, since the substance cannot be changed while the accidents remain; that transsubstantiation is not taught in the Gospels; that confession is not necessary to salvation; that no one after Urban VI should be recognized as Pope; and that it is unscriptural for ecclesiastics to hold temporal possessions. Of the erroneous doctrines, several seriously limited the right of excommunication in a distinctly

Protestant sense, one asserted the right of unlicensed preaching, another declared that dominion, whether civil or ecclesiastical, could not belong to one in mortal sin, and another distinctly asserted the authority of the temporal power over the ecclesiastical in temporal affairs. Wiclif unmistakably made his appeal to Scripture as of higher authority than Church tradition or decrees, and had a strong sense of the individualistic basis of religion. He never reached the Lutheran doctrine of justification by faith, but from denunciation of abuses in the Church rapidly advanced to his three main positions: that all dominion was of divine origin and was forfeited by anyone in mortal sin; that transsubstantiation was a doctrine both unphilosophical and unscriptural; and that monasticism in every form was a corrupt institution.

At first he attacked only the luxurious and corrupt orders of monks and was on friendly terms with the friars, but from about 1379 the friars were also included in his condemnation. He was one of the last of the realists in philosophy, and he tried to reconcile predestination with the freedom of the human will. Not only was Wiclif one of the chief forerunners of the Reformation, but he was also a pioneer in English prose literature. He wrote many learned works in Latin, but the nature of his message and the necessities of his position led him to appeal to the people in works in their own tongue. His chief Latin works are 'De Dominio Divino'; 'De Dominio Civili'; 'De Officio Pastorali,' and 'Trialogus.' All, except the 'Trialogus' and the 'De Officio Pastorali,' and also volumes of Latin sermons and a volume of Polemical Works, have been edited by English and foreign scholars for the Wiclif Society. The excepted words were edited by Lechler (1869 and 1863 respectively). His translation of the Bible was edited by Forshall and Madden (1850); and his English works are to be found in the three collections 'Three Treatises of John Wycliffe' (1851), by Todd; 'Select English Works of Wyclif' (1869–71), by T. Arnold; and 'The English Works of Wyclif' hitherto unprinted (1880, Early English Text Society), by F. D. Matthew.

Bibliography.—Lechler, 'Johann von Wiclif und die Vorgeschichte der Reformation' (1873); Poole, 'Wycliffe and Movements for Reform' (1889), and 'History of Mediæval Thought' (1884); Buddensieg, 'Johann Wiclif und seine Zeit' (1885); Stevenson, Jos., 'The Truth About John Wiclif'; Gasquet, F. A., 'The Eve of the Reformation'; and Cadman's article on Wycliffe in 'Three Religious Leaders of Oxford' (New York 1916); Workman, H. B., 'John Wyclif, a Study of the English Mediæval Church' (2 vols. Oxford 1926); and 'Summa de ente,' etc., ed. by S. Harrison Thomson (1930).

WIDDIN, vĭd'ĭn, or **VIDIN,** Bulgaria, a town on the right bank of the Danube, near the Serbian frontier, consisting of three parts, the town on the Danube, the walled city and the citadel. The principal buildings are the palace, several mosques with lofty minarets and a range of bazaars lining the main street. Ships can reach the town at high-water. There is a considerable trade, chiefly in corn, wine and salt, and the chief manufactures are gold and silver filigree work and jewelry. Widdin was formerly strongly fortified and during Russo-Turkish wars was important strategically, but the Treaty of Berlin (1878), which erected Bulgaria into a hereditary principality tributary to the Porte, decreed that its fortifications should be dismantled. Pop. (1926) 18,611.

WIDE AWAKES, in American political history, a name adopted by numerous Republican campaign clubs organized for the purpose of aiding in the election of Abraham Lincoln during the Presidential campaign of 1860. The first club was organized in Hartford, Conn. It is stated that in New York City there were on one occasion 20,000 Wide Awakes marching in procession.

WIDE, WIDE WORLD, The, a tale by Susan Warner, published in 1851 under the pen name of "Elizabeth Wetherell." It reached a sale of over 300,000 copies. The life of the heroine, Ellen Montgomery, is followed from early childhood to her marriage with a fullness of particulars which leaves nothing to the reader's imagination. The scenes and episodes are those of a homely, every-day existence, described with close fidelity to detail. Ellen's spiritual experience is minutely unfolded, and the book was long regarded as one of those which are "good for the young." The criticism of a later generation pronounces it mawkish in sentiment and unreal in conduct. It stands among the fading fancies of an earlier and less exacting literary taste.

WIDENER, Peter A. Brown, American capitalist: b. Philadelphia, Pa., 13 Nov. 1834; d. 6 Nov. 1915. He acquired a large fortune in the meat business, entered politics, was appointed city treasurer of Philadelphia in 1873 and in 1874 was re-elected to that office. He became largely interested in street railway corporations, and was associated with both the tobacco and Standard oil groups of capitalists. In 1897 he presented to the city of Philadelphia his private residence, valued at $600,000, for a branch of the Free Lending Library, and in the following year gave to the library a collection of 500 rare books valued at $28,000. In 1899 he endowed at Philadelphia the Widener Memorial Training School for Crippled Children, a combined home, hospital and school. The school site consists of a tract of 36 acres at Logan, a Philadelphia suburb.

WIDGEON, or **WIGEON,** a river-duck of the genus *Mareca.* Widgeons have a short bill, rounded at the tip, with a strong, broad nail, and the upper lamellæ prominent; wings long and pointed; tail, moderate and wedge-shaped. There are about 10 species in various parts of the world. They are found on the seashore and on the margins of lakes and rivers, feeding chiefly on vegetable substances, and performing periodical migrations at night in vast flocks. The American widgeon or baldpate (*M. americana*) is about 18 inches long; the bill is blue, black at the base and tip; upper parts finely waved transversely with dark lines; lower parts mostly white; top of head nearly white, with a broad green patch around and behind the eyes; the rest of the head and neck grayish, spotted and banded with black; the wing-covers are white, the greater part tipped

with black; the speculum is green, encircled by black. The baldpate is found throughout North America, breeding chiefly north of the United States and wintering in Central America. It is an active bird, with a swift and well sustained flight, in ranks of various and irregular forms, and it associates during the winter with teals and other ducks. The flesh is highly esteemed, especially when they have fed in the rice fields of the South, or along with the canvas-back on the water-celery of the Chesapeake. They do not dive, but feed with the head and neck immersed, swimming very near together. Their food consists of aquatic seeds, roots, insects, worms, small fry, leeches, nuts and grain, especially rice in the rainy season; being very fond of the tender aquatic plants on which the canvas-back feeds, and no diver itself, it watches the latter and snatches the morsels as it emerges and before it has had time to open its eyes. They are among the most difficult ducks to shoot, owing to their shyness and swift, irregular flight. The nest is built on the ground, often far from water and usually of leaves lined with down. The eggs number eight or 10, are pure ivory white and about two inches long by nearly one and one-half in diameter. The European widgeon (*M. penelope*) is rather smaller, and not uncommon all along the Atlantic Coast of the United States, as well as on the Pacific. It differs chiefly in having the head and neck reddish brown or cinnamon, the top of the head cream-colored. Consult Phillips, J. C., 'Natural History of the Ducks' (4 vols. 1922–26).

WIDNES, England, a manufacturing town in Lancashire, on the Mersey, opposite Runcorn, 13 miles east-southeast of Liverpool. There are extensive chemical, alkali and soda works; soap, candle, grease and manure works; copper-smelting works and rolling-mills, and iron-foundries. The town has a considerable carrying trade, which has been further developed by the construction of large docks in 1866, extended in 1884. Pop. 38,879.

WIDNMANN, vĭd'n-män, **Max,** German sculptor: b. Eichstätt, Bavaria, 13 Oct. 1812; d. Munich, Bavaria, 3 March 1895. He was educated at Munich and at Rome, executing while at the latter city his "Shield of Hercules," considered one of his masterpieces, and in 1849 became professor of sculpture at the Academy of Art at Munich. Several of the public monuments in that city are by him, but his best work is considered to be shown in his busts and statuettes, which, however, are fewer in number. His statues include those of Orlando de Lasso (1848); Schiller (1863); Goethe (1868); Castor and Pollux (1877). Specimens of his workmanship are to be found at Bamberg, Ratisbon, Würzburg and other cities.

WIDOW, one who has lost her husband by death and remains unmarried. A "grass-widow" is a divorced woman. Among the ancients was practised a form of funeral sacrifice, in which the widow was slain or induced to commit suicide so that she might be buried with her husband and accompany him to the world of spirits. This practice is mentioned as existing among the Greeks by Euripides and Pausanias, and from Cæsar it may be inferred that it existed also in Gaul. Widow sacrifice is still the custom in some African tribes; traces of it may be found in China; it lingered till late in the first half of the 19th century in Fiji, and though abolished by law in British India in 1829, was not wholly stamped out until late in the 19th century.

WIDOW BEDOTT (bĕ-dŏt') **PAPERS, The,** a collection of broadly humorous sketches by Frances Miriam Whitcher, which appeared first in Neal's *Saturday Gazette* of Philadelphia, about 1847, and in book form in 1855. They were extremely popular in their day and are still read and quoted from, though they have been followed by many works in a similar vein.

WIDOW-BIRD. See WHYDAH-BIRD.

WIELAND, vē'länt, **Christoph Martin,** German author: b. in the Swabian village of Oberholzheim, near Biberach, 5 Sept. 1733; d. Weimar, 20 Jan. 1813. The son of a country clergyman, after thorough preparation, he went in 1750 to the University of Tübingen to study law, but most of his time was devoted to *belles-lettres.* In 1751 appeared his 'Zwölf Moralische Briefe,' which met with very favorable reception. He also wrote at this time the didactic poem, 'Anti Ovid.' In 1752 he went to Zurich as a literary companion to J. J. Bodmer (q.v.). Inspired by the deeds of Frederick the Great to write a poem exhibiting the ideal of a hero, he chose the story of Cyrus. The first five cantos appeared in 1759, but the poem remained unfinished. About this time he published 'Araspes and Panthea,' an episode from the 'Cyropædia' of Xenophon. After a brief residence he left Bodmer's house, became a tutor, and in 1760 returned to Biberach. In 1762 he went to live with Count Stadion, an accomplished scholar, but a thorough man of the world, averse to all religious enthusiasm. Wieland had been prone to religious mysticism; but the gay pleasure-seeking life of the society with which he now came in contact, and the sceptical and cynical kind of literature now most at his command, produced an entire change of sentiment. The first indication of this new philosophy of life appears in the tale of 'Nadine,' which he styles a composition in Prior's manner. This was followed in 1764 by 'Die Abenteuer des Don Sylvio de Rosalva' ('The Adventures of Don Sylvio de Rosalva'), a work for which Don Quixote serves as model. In 1766–67 appeared his 'Agathon,' which established his reputation. The 'Musarion' (1768), a production distinguished for grace, ease and harmony, advocates a rational unity of the sensual and spiritual. In 1770 he wrote 'Die Grazien' ('The Graces'); and the 'New Amadis' in 1771, a poem which celebrates the triumph of intellectual over mere physical beauty. In 1769 he was appointed *professor primarius* of philosophy at the University of Erfurt. In his 'Verklagter Amor' ('Cupid Accused') he defended amatory poetry; and in the 'Dialogen des Diogenes von Sinope' (1770) gave a general vindication of his philosophical views. In 1772 he was invited to Weimar by the Duchess Anna Amalia as tutor to her two sons. Turning his attention to dramatic poetry, he wrote the 'Wahl des Hercules' ('Choice of Hercules'), and the 'Al-

ceste.' He also edited the 'Deutscher Mercur,' a monthly, which he conducted till near the close of his life. His views, as exhibited therein, however, showed so much of the narrow conventional spirit of French criticism, that he was attacked by Goethe in the satire 'Götter, Helden und Wieland' ('Gods, Heroes and Wieland'). This Wieland answered with great good nature, recommending it to all who were fond of wit and sarcasm. Goethe and Herder were soon drawn to Weimar, where the Duchess Anna Amalia formed a circle of talent and genius, later also joined by Schiller. In 1774 appeared the 'Geschichte der Abderiten,' in which Wieland sought with an engaging wit to correct the provincialism of his time. 'Oberon' (1780), a romantic epic, is the most finished of his works. Wieland also prepared translations of Horace, Lucian and the 'Letters' of Cicero. His translations of Shakespeare (1762–66), made the English poet «an open book for Germans.» He superintended (1794–1802) an edition of his 'Works' in 45 volumes. These were also edited by Gruber (1818–28 and 1867–75), and there are many editions of selections, some of which have been translated into English. Wieland's place in literature in a sense falls within the group headed by Goethe, Schiller and Lessing, not so stellar as these, he was yet singularly attuned to his time. A veritable German Voltaire, his influence, exerted especially through the 'Deutscher Mercur,' was immense. Of facile and incessant wit, no other writer had more to do with shaping the German language to elegant expression. This explains the delight with which the work of Wieland was met in his day. Consult Loebell, 'Entwickelung der Deutschen Poesie' (1858); Ranke, 'Zur Beurtheilung Wielands' (1885); Hirzel, 'Wieland's Beziehungen zu den deutscher Romantikern'; Lenz, W., 'Wieland's Verhältniss zu Spenser, Pope, und Swift'; and Gruber's biography, with his editions.

WIENER, vē'nèr, **Leo,** Jewish-American author: b. Russia, 26 July 1862; d. Belmont, Mass., 13 Dec. 1939. He was educated at Minsk, at the University of Warsaw and the Polytechnic of Berlin. From the latter city he went to New Orleans, worked in a cotton factory, and later sold fruit in Kansas City, Mo. He then obtained a position as teacher in Odessa, Mo., and afterward a professorship in the University of Missouri. He was appointed assistant professor of Slavonic languages at Harvard in 1901; professor in 1911. He contributed many etymologies to Webster's New International Dictionary, but his greatest editorial production is the 24-volume compilation of Count Tolstoy's works. Among his other publications are 'History of Yiddish Literature in the 19th Century'; 'Contributions Toward a History of Arabico-Gothic Culture' (4 vols. 1917); 'Africa and the Discovery of America' (3 vols. 1919); 'Mayan and Mexican Origins' (1926).

WIENER-NEUSTADT, vē'nĕr-noi'stät, Austria. See NEUSTADT.

WIERTZ, vērts, **Anton Joseph,** Belgian painter: b. Dinant, 22 Feb. 1806; d. Brussels, 18 June 1865. He studied art in the Antwerp Academy, where he gained, in 1832, a prize which enabled him to continue his studies in Rome. On his return to Belgium he lived at Liège for a time, and from 1848 at Brussels, where the Belgian government erected a large studio for him in 1850. Wiertz was a painter of great, though eccentric, genius, with a strange predilection for horrible and fantastic subjects, and invented a method of painting, called by himself *peinture mate,* in which the characteristics of fresco and oil painting are combined. His principal pictures are 'Greeks and Trojans contending for the Body of Patroclus'; 'The Flight into Egypt'; 'Death of Dionysius'; 'The Triumph of Christ' (1848), his masterpiece; 'The Things of To-day in the Eyes of the Men of the Future'; 'The Beacon of Golgotha'; 'The Last Cannon'; 'Napoleon in Hell'; 'A Second after Death.' He did not sell any of his chief paintings, which he bequeathed to the state, but supported himself by painting portraits. His Brussels studio, fitted up after his death as the Musée Wiertz, contains his large pictures. He wrote 'Eloge de Rubens' (1840); and 'Caractères Constitutifs de la Peinture Flamande' (1863). Consult Labarre, 'Antoine Wiertz' (1866).

WIESBADEN, vēs'bä-dĕn, Prussia. A town in the province of Hesse-Nassau, formerly capital of the government of Wiesbaden, and capital of the Duchy of Nassau, beautifully situated among vineyards and orchards on the southern slopes of the Taunus range, about three miles north of the Rhine and 20 miles west of Frankfort. For many years it attracted about 80,000 visitors from all parts of Europe by its baths. Among notable buildings are the royal palace, the ducal palace, the town-house, the government buildings, the courthouse, the museum and picture-gallery, the library (100,000 vols.), the royal court theatre, the Trinkhalle, and the Kurhaus, consisting chiefly of a large and splendid saloon, forming the east side of a square, while the north and south sides are lined by colonnades, filled with gay shops, and uniting a promenade and a bazaar. The springs, all of which except one are alkaline and among the most powerful of their class, are very numerous, and have temperatures varying from 100° to 153° F. The springs of Wiesbaden are spoken of by Pliny as the «Fontes Mattiaci,» and on the Heidenberg, north of the town, traces of a Roman fortress were discovered in 1838, which seems to have been connected with the town by a wall, the Heidenmauer («heathen's wall»), in the ruins of which votive tablets and inscriptions have been discovered. Wiesbaden thrives principally on its popularity as a winter and summer watering-place, but also does a large business in wine and has manufacturing establishments for chocolate, surgical instruments, etc. The population is 151,961.

WIFE. See HUSBAND AND WIFE.

WIG, an artificial hair covering for the head to conceal baldness, or to alter the appearance. They are usually made of human hair woven into a cap that fits the head tightly. Those worn for baldness are politely termed toupees. The use of wigs is traced back to the ancients. They were used especially by the women. The fashion is said to have been copied by the Greek

ladies from those of Egypt. Under the Roman emperors it became common even for men to wear wigs, and several of the emperors themselves used this ornament. In the latter half of the 16th century the fashion became much in vogue in France, Italy and England. In 1560 no lady appeared at the French court without a blonde wig. Louis XIII set the fashion, wearing a wig of long curls, being himself bald. The courtiers naturally followed. Louis XIV was at first averse to wigs; but in the latter part of his reign, when he began to lose his own hair, he reintroduced the fashion, which went to a greater extreme than ever. About 1660 they began to be worn by the clergy, who had at first shown themselves hostile to the practice. The practice of powdering these wigs was adopted about the year 1700. About 1720 the great wig began to give place to the queue, which remained the fashion till early in the 19th century. Modern refinement has abolished the wig as an ornament except in Great Britain for the lord-chancellor, judges and barristers. They are still worn by actors and actresses as a part of the make-up or dress suitable to a particular character.

WIGAN, England, a town of Lancashire, on the Douglas, 21 miles northeast of Liverpool. Wigan stands in the centre of an extensive coal field, and its manufactures, which are important, consist chiefly of calicoes, fustians and other cotton goods, linens, checks, cotton twist, etc., besides iron foundries, iron forges, railway car works, iron rolling mills, large breweries, chemical works and corn and paper mills. It has a Mining and Technical College. Pop. 84,000.

WIGGIN, Kate Douglas Smith, American author: b. Philadelphia, Pa., 28 Sept. 1859; d. London, England, 24 Aug. 1923. She was educated at Abbott Academy, Andover, Mass., and in 1876 went to Los Angeles, studying the kindergarten system there, and later at San Francisco organized the first free kindergarten in the West. In 1880 she married S. B. Wiggin, a lawyer (d. 1889), and removed to New York. In 1895 Mrs. Wiggin was married to George C. Riggs. In 1906 Bowdoin College gave her the Litt.D. degree. She published, with her sister, Nora A. Smith, 'Froebel's Gifts' (1895); 'Kindergarten Principles and Practice' (1896), etc. Her other works, several of which have attained great favor in this country and England, include 'The Bird's Christmas Carol' (1888); 'The Story of Patsy' (1889); 'A Cathedral Courtship' (1893); 'Mann Lisa' (1896); 'Penelope's Progress' (1898); 'Penelope's Experience in Ireland' (1901); 'Diary of a Goose-girl' (1902); 'Rebecca of Sunnybrook Farm' (1903); 'New Chronicles of Rebecca' (1907); 'Susanna and Sue' (1909); 'Mother Carey's Chickens' (1911; dramatized 1915), etc.

WIGGINS, Benjamin Lawton, educator: b. Sand Ridge, S. C., 11 Sept. 1861; d. Sewanee, Tenn., 1909. His education was received at the University of the South from which he was graduated in 1880. He afterward (1883–84) pursued graduate work at Johns Hopkins University. In 1882 he returned to the University of the South as professor of Greek, which position he held until his death, with the added duties (after 1893) of vice-chancellor or president. Under his supervision the University of the South became one of the leading institutions in the Southern States.

WIGGINS, (John) Carleton, American artist: b. Turners, N. Y., 4 March 1848. He studied at the National Academy of Design in New York and under George Inness and H. Carmiencke and later in Paris. He first exhibited at the National Academy in 1870, and at the Paris Salon in 1881. He painted landscapes, and was especially successful in his paintings of cows. He was elected to the National Academy in 1906. His works are well represented in both public and private collections. Among them are 'A Holstein Bull' (Metropolitan Museum of Art, New York); 'Morning on the Hills' (Brooklyn Museum); 'October' (Corcoran Art Gallery, Washington); 'Lake and Mountains' (Chicago Art Institute); 'Evening after a Shower' (National Gallery, Washington); 'The Wanderers' (Hamilton Club, Brooklyn); 'Ploughing in France'; 'Plough Horse' (Lotus Club, New York). D. 12 June 1932.

WIGGINS, Guy Carleton, American artist, son of (J.) C. Wiggins (q.v.): b. Brooklyn, N. Y., 23 Feb. 1883. He studied under his father and at the Polytechnic Institute, Brooklyn, and the National Academy of Design, New York. He is notably successful in his portrayal of scenes in New York, and is also known for his landscapes. Among his works are 'Metropolitan Tower' (Metropolitan Museum, New York); 'Columbus Circle, Winter' (National Gallery, Washington); 'Berkshire Hills, June' (Brooklyn Museum), etc. He was made full member of the National Academy in 1935.

WIGGINS, Joseph, English sea captain and explorer: b. Norwich, 3 Sept. 1832; d. Harrogate, 13 Sept. 1905. He was apprenticed to his uncle, a shipowner, at the age of 14 and at 21 rose to be master of a ship. He afterward became owner of several cargo vessels and developed a keen interest in the project of developing a trade route between the countries of northern Europe and Siberia by means of the Northeast Passage through the Arctic seas. His first voyages, in 1874, 1875, 1876 and 1886–87 were less successful for the actual cargo delivery than for their awakening of interest in the matter and for his brilliant achievements as a navigator, demonstrating the possibility of taking ships far beyond any point hitherto reached. In 1887 he sailed up the Yenisei River to Yeniseisk. His first notable achievement in the delivery of a cargo was that of a shipment of rails for the Trans-Siberian Railway, in 1893, for which feat he was honored by the tsar. He made another successful visit to Yeniseisk in 1895. He was selected to take charge of a relief expedition into Siberia at the time of the famine in 1905 but died while preparations were under way. He received in 1894 the Murchison Medal of the Royal Geographical Society. Consult Johnson, H., 'Life and Voyages of Joseph Wiggins' (London 1907).

WIGGLESWORTH, wĭg'lz-wĕrth, **Michael,** American Puritan clergyman: b. Yorkshire, England, 1631; d. Malden, Mass., 10 June

1705. In 1638 he was brought to Charlestown, Mass., by his father and accompanied him in the same year to New Haven, Conn. He was graduated from Harvard in 1651, subsequently becoming a tutor there. He then studied theology and was settled as pastor of the Church of Malden in 1656. He was accounted skilful in medicine, and was offered the presidency of Harvard in 1684, but on account of ill health declined the honor. His best-known work, 'The Day of Doom' (1662), was a popular poem in New England for a long period. Two editions were printed in England and the sixth edition in New England appeared in 1715. The savage Calvinism of the poem is unsurpassed in literature save perhaps in Jonathan Edwards' sermon, 'Sinners in the Hands of an Angry God,' but the work contains not a little dramatic force and here and there passages of dignity and beauty. He also wrote 'God's Controversy with New England' and 'Meat out of the Eater,' in verse; and 'A Discourse on Eternity.' Consult Tyler's 'History of American Literature' (1878); and Dean, 'Memoir of Michael Wigglesworth' (1863; new ed., 1871).

WIGHT, wīt, **Orlando Williams,** American physician and translator: b. Centreville, N. Y., 19 Feb. 1824; d. Detroit, Mich., 19 Oct. 1888. He was educated at the Rochester Collegiate Institute, removed to New York in 1847, studied theology and was ordained to the Universalist ministry. He subsequently studied medicine, being graduated from the Long Island College Hospital in 1865. He engaged as a medical practitioner in Wisconsin, and was appointed State geologist and surgeon-general in 1874. He was health commissioner of Milwaukee in 1878–80, and health officer of Detroit in 1882–88. He was a noted translator and throughout his life devoted a large share of his time to literary work. He wrote 'Maxims of Public Health' (1884); 'Peoples and Countries Visited' (1888), etc. His translations include 'History of Modern Philosophy,' with F. W. Ricord (1852); 'Lives and Letters of Abélard and Héloïse' (new ed., 1861); Martin's 'History of France,' with Mary L. Booth (1863), etc. He also edited 'Standard French Classics' (14 vols., 1858–60); 'The Household Library' (18 vols., 1859, et seq.), etc.

WIGHT, William Ward, American lawyer: b. Troy, N. Y., 14 Jan. 1849. He was graduated at Williams College in 1869, and the Albany Law School in 1873. He began law practice in Milwaukee in 1875. Among his services were Fire and Police Commissioner, president of the board of Milwaukee-Downer College (1907–24), and president of the State Historical Society of Wisconsin. He wrote 'Life of Henry Clay Payne,' etc. Died 2 Jan. 1931.

WIGHT, Isle of, England, off the south coast, in the county and opposite to the mainland portion of Hants, is separated from the mainland by the roadstead or channel of Spithead on the east, and by the Solent or continuation of this on the west. It is about 23 miles in length from east to west, by 15 miles broad; circuit about 70 miles; area, 146 square miles. The land is rolling, affording agreeable scenery; the air is remarkably healthful. Only a small portion of the surface is waste. The downs, which cross the island from east to west and form excellent sheep-walks, separate it into two districts, which in their general character contrast with each other, the soil on the north side being generally a stiff, cold clay, and on the south side a fertile sandy loam. On the promontory that forms the western extremity of the island are three notable chalk cliffs locally called the "Needles." Celtic tumuli occur on a number of the chalk downs, and there are monoliths of geologic interest. Excellent cement is manufactured at the works on the west side of the Medina, and largely exported. The chief imports are cattle, coal, timber and building material. The island is well defended, being protected on the east side by Sandown Fort, Bembridge Fort and Battery, and by other forts which lie between the island and the mainland. The western approach is guarded by Hurst Castle and other forts. The chief towns are Newport (the capital), Ryde, Cowes, Ventnor, Brading, Yarmouth and the fashionable health resorts of Sandown and Shanklin on the southeast coast. Osborne, near Cowes, was a residence of Queen Victoria, and with its beautiful grounds is now a national memorial, the gift of Edward VII. Its most recent use is as a college for naval cadets. Among the antiquities of the Isle of Wight the most interesting is Carisbrooke Castle, which stands a little southwest of Newport, and consists of extensive and well-preserved picturesque ruins. It has many historical associations: it is supposed to have originally been a fortress of the Britons, was afterward repaired and enlarged by the Romans, was considerably strengthened under Cerdic, who founded the kingdom of Wessex, and rebuilt in the reign of Henry I. During the Parliamentary War it became the asylum of King Charles I on his escape from Hampton Court, and afterward his prison. Another interesting remain is Quarr Abbey, about two and one-half miles from Ryde, which was built in 1132, and is now a farmhouse. Pop. 88,454. Consult Thomas's 'Isle of Wight' (Boston 1912).

WIGMORE, John Henry, American lawyer and university dean: b. San Francisco, 4 March 1863; d. Chicago, Ill., 20 April 1943. One of America's great authorities on the law of evidence, he was graduated from Harvard; practiced law at Boston, 1887–89; thereafter was professor of Anglo-American law at Keio University, Tokyo, Japan, for three years, and from 1893 was professor of law at Northwestern University (dean of the law faculty, 1901–29). He published 'Digest of the Decisions of the Massachusetts Railroad Commission' (1888); 'The Australian Ballot System' (1889); 'Notes on Land Tenure and Local Institutions in Old Japan' (1890); 'Materials for the Study of Private Law in Old Japan' (1892); 'Treatise on Evidence' (4 vols., 1904–05; 5 vols., 1923); 'Pocket Code of Evidence' (1909); 'Principles of Judicial Proof' (1913). He edited the 16th edition of 'Greenleaf on Evidence' (1899); Compiled 'Examinations in Law' (1900); 'Cases on Torts' (2 vols. 1911); 'Cases on Evidence' (1913), and coeditor of 'Select Essays in Anglo-American Legal History' (1907); 'Evolution of Law Series' (1915); 'Panorama of the World's Legal Systems' (1929). Mr. Wigmore was president of the American Institute of Criminal Law and Crim-

inology 1909–1910, and 1916–1919, served on the staff of the judge advocate general of the United States. In February 1917 he was appointed a member of the United States High Commission.

WIGNER, Eugene Paul, mathematical physicist: b. Budapest, Hungary, November 17, 1902. Educated as a chemical engineer at the Technische Hochschule, Berlin, he taught there until 1930. Coming to the United States he became professor of mathematical physics at Princeton University, held the same position at the University of Wisconsin during 1937–1938, returning to Princeton in the latter year. Associated at an early date with the preliminary organization of nuclear research in the United States, he was one of a group of foreign-born scientists who helped to secure government sponsorship for it. During the period of the Manhattan Project he did research at the University of Chicago Metallurgical Laboratory and other atomic bomb installations. After the war, on leave of absence from Princeton, he became director of research at the Clinton Laboratories, Oak Ridge, Tenn. He returned to his university duties in 1947. In addition to many papers on nuclear theory, he has applied the mathematical methods of group theory to quantum mechanics, and molecular structure, has been interested in theories of reaction rates and has developed theories of the solid state. His book *Gruppentheorie und ihre Anwendung auf die Quantenmechanik der Atomspektren,* written in 1931 is widely used as an advanced text in quantum mechanics.

WIGTOWN, or **WIGTON,** county forming the southwest corner of Scotland; bounded west by the North Channel, north by Ayrshire, east by the Stewartry of Kirkcudbright and the Solway Firth, and south by the Irish Sea. The extent from east to west is about 33 miles, from north to south about 26 miles; area, 487 square miles, of which about 46 per cent is arable. This county which constitutes West Galloway was formed about 1341. It lies between latitude 54° 38′ and 55° 4′ N., and longitude 4° 16′ and 5° 6′ W. Wigtown is somewhat irregular in form, being deeply intersected by two arms of the sea. The western part of Wigtown, known as the "Rhins of Galloway," forms a peninsula; its northern extremity is Corsewall Point, and its southern the Mull of Galloway. The southeastern half of Wigtown extends south in a blunt triangular form, terminating in Burrow Head. The soil is varied, and except a portion along the seashore, especially in the southeastern part which consists of a rich loam—the quality is inferior. The climate is mild but moist, the rainfall being comparatively great. There are many dairy establishments. Wigtown contains three rivers of considerable size, the Cree, the Bladnoch, and the Luce—the Cree and Bladnoch being navigable for a few miles. Small freshwater lochs are numerous. There were at an early period many religious houses in the county and the church, believed to be the oldest in Scotland, founded by Saint Ninian, was built near the site of the present village of Whithorn. The principal towns are Wigtown, Newton-Stewart, Stranraer, and Whithorn. Pop. (1931) 29,299; (1951) 31,625.

WIGWAGGING, a system of visual signaling by means of hand flags. See SIGNALS AND SIGNALING.

WIGWAM, wĭg′wŏm, among the American Indians a lodge, cabin, hut or tent, generally of a conical shape, formed of bark or mats laid over stakes planted in the ground, and converging toward the top, where there is an opening for the escape of the smoke. The most common form is the tepee, which is portable, being usually a framework of roughly trimmed poles, lashed together with split wood, or thongs, and covered with hides, bark, or matting. Those designed to be more permanent, approached the log house or bark shack in construction. The word has also been applied to a large temporary structure for public gatherings.

WILBER, wĭl′bĕr, city, Nebraska, and Saline County seat; altitude 1,325 feet; on the Blue River; 31 miles southwest of Lincoln; on the Burlington Railroad. It is in a region growing wheat and corn abundantly. Settled in 1873, it was named for C. D. Wilber of the University of Nebraska, who platted it. It has a library, and municipal water, power, and light systems. A city of the second class, its government is administered by mayor and council. Pop. (1940) 1,355; (1950) 1,358.

WILBERFORCE, Henry William, English journalist and author: b. Clapham, England, Sept. 22, 1807; d. Stroud, Gloucestershire, April 23, 1873. He was the youngest son of William Wilberforce (q.v.). Educated at Oriel College, Oxford, during his holidays he read with John Henry (later Cardinal) Newman. He entered Lincoln's Inn but abandoned law for theology, and was ordained in the Church of England in 1834. He held several vicarages between 1841 and 1850 at which time he entered the Catholic Church. He wrote *The Parochial System* (1838); *Proselytism in Ireland* (1852); *The Church and the Empires: Historical Periods* (1874). He was the proprietor and editor of the *Catholic Standard,* a London newspaper, from 1854 to 1863.

WILBERFORCE, wĭl′bĕr-fôrs, **Robert Isaac,** English clergyman, 2d son of William Wilberforce (q.v.): b. Clapham, Surrey, England, Dec. 19, 1802; d. Albano, Italy, Feb. 4, 1857. He was graduated from Oriel College, Oxford, in 1823, and was subsequently chosen fellow of his college, associating in that capacity with Edward Bouverie Pusey and John Henry Newman, Hurrell Froude and other leaders of the High Church party. In 1830 he left Oxford to take charge of a parish, and became vicar in 1840 of Burton Agnes, Yorkshire.

WILBERFORCE, Samuel, English prelate, 3d son of William Wilberforce (q.v.): b. Clapham, Surrey, England, Sept. 7, 1805; d. near Dorking, Surrey, July 19, 1873. He was graduated from Oriel College, Oxford, in 1826, ordained deacon in 1828, and appointed curate of Checkendon, Oxfordshire, the same year. He was rector of Brightstone, in the Isle of Wight, 1830–1840, in 1839 became archdeacon of Surrey, and in 1840 a canon of Westminster. In the last-named year also he became rector of Alverstoke, Hampshire. He received the deanery of Westminster in March 1845, but before the close of that year was promoted to the bishopric of Winchester. He was the leader of the High Church party, though much opposed to ritualism, and was both witty and eloquent as well as a skillful debater in the

House of Lords. His readiness in argument and his versatile qualities gained him the title of "Soapy Sam." He published *Notebook of a Country Clergyman* (1833); *Eucharistica* (1839); *A History of the Protestant Episcopal Church in America* (1844); *University Sermons.*

Consult the *Life* by his son, R. G. Wilberforce (1888); Daniell, G. W., *Bishop Wilberforce* (1891).

WILBERFORCE, William, English philanthropist: b. Hull, Yorkshire, England, Aug. 24, 1759; d. London, July 29, 1833. Educated at Cambridge, he was in 1780 elected member of Parliament for his native town; and in 1784 was returned both by his former constituency and by the County of York. He chose to represent the latter. In 1786 he made the acquaintance of T. Clarkson, who gained his sympathies on behalf of the agitation against the slave trade, to which he henceforth devoted all his energies in Parliament until the agitation proved successful. He first called the attention of the house to the subject in 1787, and in 1791 moved for leave to bring in a bill to prevent further importation of African Negroes into the British colonies. Year after year he pressed this measure, but was defeated until 1807, when it was passed during the short administration of H. Fox. Having secured the abolition of the slave trade in the British colonies, he addressed himself to the task of obtaining emancipation for those already reduced to or born in slavery. In 1812, after having sat for Yorkshire in six Parliaments, he withdrew from the representation, and until 1825, when he retired from Parliament, sat for the borough of Bramber. He died shortly after the government plan for the total abolition of slavery in the British colonies had passed in the House of Commons. His remains were interred in Westminster Abbey, and his funeral was attended by distinguished men of all parties. Wilberforce was the author of a treatise entitled *A Practical View of the Prevailing Religious Systems of Professed Christians in the Higher and Middle Classes contrasted with Real Christianity* (1797).

Consult *Life of William Wilberforce* by his sons (1838); his *Correspondence* (edited 1840); and *Private Papers of William Wilberforce* (edited 1897).

WILBERFORCE UNIVERSITY, an institution of higher learning, is located at Wilberforce, Ohio. It was founded in 1856 by the Methodist Episcopal Church, and in 1863 was purchased by the African Methodist Episcopal Church under whose auspices it has since operated. It includes a college of liberal arts, a college of education, a theological seminary, and a school of vocations. The liberal arts college offers courses leading to the A.B. and B.S. degrees with majors in social administration, journalism, and music, in addition to the regular classical and scientific courses. It also offers preprofessional training for law, medicine, dentistry, and engineering. The college of education offers the degree B.S. in education and trains teachers for the elementary and high school grades as well as teachers for agriculture, commerce, industrial arts, health and physical education, home economics, and public school music. The theological seminary offers a three-year course leading to the degree B.D. The school of vocations offers courses in automotive service, electricity, building construction, printing, and food administration. The grounds and buildings are valued at $2,200,000 and there is a yearly income of $400,000. The approximate annual enrollment is 406.

WILBOUR, Charlotte Beebe, American woman-suffrage worker: b. East Hartford, Conn., March 2, 1833; d. New York, Dec. 25, 1914. She was educated at the Wilbraham (Mass.) Academy, and was married to Charles E. Wilbour, an Egyptologist, in 1858. She was associated with Susan B. Anthony and Elizabeth Cady Stanton as a worker for suffrage for women, and became known as a public speaker of much force and eloquence. She was one of the founders of the Sorosis Club in New York in 1868, which in 1869 became the first incorporated women's club in the United States.

WILBUR, wĭl'bẽr, **Curtis Dwight,** American public official: b. Boonesboro (now Boone), Iowa, May 10, 1867; d. Palo Alto, Calif., Sept. 8, 1954. A graduate of the United States Naval Academy (1888), he practiced law in Los Angeles, was elected judge of the superior court (1903–1918), and then associate justice of the state supreme court, serving as chief justice from 1922. He was secretary of the navy (1924–1929) and judge of the 9th United States Circuit Court of Appeals (1929–1945).

WILBUR, John, American preacher of the Society of Friends: b. Hopkinton, R. I., July 17, 1774; d. there, May 1, 1856. He was a teacher and surveyor, who was a strongly conservative member of the Society of Friends. For his alleged statements reflecting on J. J. Gurney (q.v.), the English Quaker, he was denounced by several members of the Rhode Island yearly meeting of 1838. Wilbur's adherents later withdrew from the orthodox society and formed an independent conservative yearly meeting whose members were styled Wilburites (q.v.). Among Wilbur's writings, largely polemical, was *A Narrative and Exposition* (1845).

WILBUR, Ray Lyman, American educator and statesman: b. Boonesboro, Iowa, April 13, 1875; d. Palo Alto, Calif., June 26, 1949. He was educated at Leland Stanford (now Stanford) University, Cooper Medical College, and in Germany and England. He was appointed to the chair of medicine at Stanford in 1909, became dean of the Medical School in 1911, president of the university in 1916, and chancellor for life in 1943. On leave of absence from the university, he was secretary of the interior in the Hoover cabinet (1929–1933). Dr. Wilbur was a member of many local and national organizations interested in public affairs, the advancement of education, health and welfare. From 1923 to 1940, he was a trustee of the Rockefeller Foundation; in 1925, chairman of the Institute of Pacific Relations in Honolulu, and from 1943 until his death, he was chairman of the advisory committee of the Army Specialized Training Program.

WILBURITES, a branch of the Society of Friends or Quakers, who adopted the principles of the Rev. John Wilbur (q.v.) in 1827, and maintained an independent yearly meeting. Having become a preacher of the Society of Friends, Wilbur took a strongly conservative stand against what he regarded as innovations antagonistic to the original doctrines of the society. Wilbur's followers, the Conservative Friends, in 1949 had 12

churches, and about 4,000 communicants. See FRIENDS, THE RELIGIOUS SOCIETY OF.

WILCOX, wĭl'kŏks, **Cadmus Marcellus,** American army officer: b. Wayne County, North Carolina, May 29, 1824; d. Washington, D.C., Dec. 2, 1890. He was graduated from the United States Military Academy in 1846, served in the Mexican War, and in 1860 was commissioned captain. In 1861 he resigned from the army and entered the service of the Confederacy. He participated in the first Battle of Bull Run, was promoted brigadier general in October, and in 1864 became major general. He was engaged in the second Battle of Bull Run, at Fredericksburg, Chancellorsville, Salem Heights, Gettysburg, and other important battles, and was present at the surrender at Appomattox Court House. He was offered a commission as brigadier general in the Egyptian Army after the close of the Civil War, but declined it. In 1886–1890 he was chief of the division of railroads at the General Land Office in Washington. He wrote *Rifles and Rifle Practice* (1859); translated from the French a work, *Austrian Infantry Evolutions of the Line* (1860); and an excellent *History of the Mexican War*, edited by his niece, Mary Rachel Wilcox (1892).

WILCOX, Delos Franklin, American public utility expert: b. near Ida, Michigan, April 2, 1873; d. New York, N.Y., April 4, 1928. He was graduated at the University of Michigan in 1894 and received his Ph.D. at Columbia University in 1896. He edited the Detroit *Civic News* in 1905–1907; was chief of the bureau of franchises of the public service commission in the first district of New York, 1907–1913; deputy commissioner of the New York City department of water supply, gas and electricity 1913–1917; adviser to the Federal Electric Railway Commission 1919–1920; and consultant on utility rates and problems for New York City from 1917.

He was author of *The Study of City Government* (1897); *City Problems* (1899); *The American City* (1904); *Municipal Franchises* (2 vols., 1910–11); *Great Cities in America* (1910); *Analysis of the Electric Railway Problem* (1921); *Depreciation in Public Utilities* (1925); *The Indeterminate Permit in Relation to Home Rule and Public Ownership* (1926).

WILCOX, Ella Wheeler, American journalist and poet: b. Johnstown Center, Wisconsin, Nov. 5, 1850; d. Sound Beach, Conn., Oct. 30, 1919. She was educated at the University of Wisconsin and in 1884 began her literary career by contributing to the periodical press. *Poems of Passion* (1883) gave her a national reputation. Her verse was widely published in daily newspapers. In later life she dealt more and more with subjects pertaining to the higher life, the brotherhood of man, faith in a future life, and reincarnation. Among her other publications, in verse, are *Drops of Water* (1872); *Shells* (1873); *Maurine* (1876); *Sweet Danger* (1902); and *The Art of Being Alive* (1914). She also wrote the novels *Mal Moulée* (1885); *A Double Life* (1890); *An Erring Woman's Love* (1892); *A Woman of the World* (1904); *The Story of a Literary Career* (1905); *Poems of Sentiment* (1906); *Historical Mother Goose* (1914); *Poems of Problems* (1914); *Lest We Forget* (1915); *The Worlds and I*, an autobiography (1918).

WILCOX, Marrion, American author: b. Augusta, Georgia, April 3, 1858; d. New York, N.Y., Dec. 26, 1926. A graduate of Yale (1878), two years later he was admitted to the New York bar, having studied law at Hamilton College. He made special studies at Oxford, Heidelberg, Jena, and Berlin universities from 1881 to 1883. From 1884 to 1886 he served as an instructor at Yale and was associate editor of the *New Englander and Yale Review*, and from 1893 was engaged in editorial and other literary work in New York. In 1902 he became noted as an advocate of fair play to Cuba, defending the principle of reciprocity in the United States and urging concessions from the political leaders and economic associations of Cuba. His principles were approximately those embodied in the treaty submitted to Congress and accepted in 1903. In 1906–1907 he visited South America and Mexico, and on his 1907 visit, at the request of Yale University, he suggested the interchange of professors between the United States and Latin American countries, stressing particularly the need for such interchange with Mexico, Brazil, and Argentina. He published *A Short History of the War with Spain* (1898); *Harper's History of the War in the Philippines* (1900); *Sketches in Spain, England and Italy*, and a novel, *For Labour*. He contributed many articles on Central and South American topics to the *Encyclopedia Americana*, and edited, in collaboration with George E. Rines, *The Encyclopedia of Latin-America* (1917).

WILCZYNSKI, wĭl-zĭn'skĭ, **Ernest Julius,** American mathematician and educator: b. Hamburg, Germany, Nov. 13, 1876; d. Denver, Colorado, Sept. 14, 1932. After attending elementary and high schools in Chicago, he returned to Germany and entered the University of Berlin where he received his doctorate in 1897. He returned to the United States and in 1898 was appointed instructor in mathematics at the University of California. Here he remained until 1907 as assistant and associate professor, except for two years (1903–1905) which he spent in Europe as research associate for the Carnegie Institution at Washington, D.C. He became known as an authority on projective differential geometry and as a leader of a new school of geometers. Many scientific honors were bestowed upon him.

WILD, vĭlt, **Heinrich von,** Swiss meteorologist: b. Uster, Switzerland, Dec. 17, 1833; d. Zurich, Sept. 5, 1902. His education was obtained at Zurich, Königsberg, and Heidelberg, and from 1863 to 1865 he was director of the central meteorological bureau at Bern. He was called to St. Petersburg (now Leningrad) and was director of the Russian meteorological service 1865–1895, when he retired. He invented the polaristrobometer, a polarization plutometer, a magnetic theodolite, and other optical instruments, edited the Russian *Neues Repertorium für Meteorologie*, and published *Temperatur-Verhaltnisse des russischen Reichs* (1876), and many technical papers.

WILD, Jonathan, English robber and informer: b. Wolverhampton, England, about 1682; d. London, May 24, 1725. He was a Birmingham buckle maker who in 1706 went to London intending to engage in his trade, but becoming involved in debt was imprisoned for

four years, after which he became a receiver of stolen goods and an informer against such criminals as were not in his employ. He was hanged at Tyburn. He was the subject of Fielding's satire, *History of the Life of the Late Mr. Jonathan Wild the Great* (1743), and also appears in Ainsworth's novel, *Jack Shepherd,* as well as in various other tales and pretended biographies.

WILD DUCK, The. Henrik Ibsen, in his ironic play *The Wild Duck* (*Vildanden*), published in 1884 and performed the year following, sought to exhibit the folly of obedience to any mere formula of conduct, a doctrine already propounded in his early poetic drama, *Brand.* Incidentally, he made clear the dangers of a shallow idealism, and challenged his admirers to decide each case of conduct on its own merits, rather than according to some nicely worded law discovered in his plays. In *The Pillars of Society* and *An Enemy of the People* Ibsen had insisted that truth and freedom are essential to social welfare; and in *A Doll's House* he had declared for perfect confidence between husband and wife. Yet in *The Wild Duck,* he lets us understand that there are instances when "the truth, the whole truth, and nothing but the truth," may work more harm than good.

A busy-body reformer, sincere though short-sighted, finds that his former classmate in college has been wedded to a woman with a past. He discovers that it is his own father who has disgraced her, and feels in duty bound to enlighten Hjalmar Ekdal and convince him of the necessity of beginning life afresh with Gina on a basis of mutual understanding. But no sooner does Hjalmar learn from the idealist reformer that his Gina has once been the mistress of another than he rebuffs her and the innocent child he had thought his own, and proposes to forsake them both. The little girl, having been taught by the meddling idealist the doctrine of self-abnegation, accepts it literally, and, instead of sacrificing only her pet duck to win back Hjalmar's love, sacrifices her dearest possession, life itself. Thus the idealist—Gregers Werle—with the best of intentions, has wrought havoc in a family hitherto happy, though in part deluded.

Quite aside from its central meaning, the play is of interest as depicting with minute fidelity a curious group of characters. Of especial note are the Ekdals, all victims of old Werle. There is the lieutenant, once his partner in a dishonest business, serving in prison as his scapegoat, and emerging to find his only pleasure in hunting pretended game in a pretended forest in an attic. There is the lieutenant's son Hjalmar, ostensibly a photographer, but in fact an idle dreamer assuming poses to deceive himself and others, mouthing conventionally when informed that old Werle has married him to Gina to conceal her fault and his. There is little Hedvig, cursed by her inheritance from old Werle with weak eyes, straining them unduly in touching up negatives for the lazy Hjalmar, for whose sake she mistakenly lays down her life. And there is Gina, loyal and industrious, the embodiment of common sense, little troubled by remorse for her past, yet unconsciously atoning for it by devotion to her husband and her child. Not the least enigmatic characters are the minor folk Molvik and Relling, the latter proclaiming the need of every creature for some life-lie, some delusion to make him happy.

Technically, the piece is noteworthy for its decorative and incidental symbolism, an insinuated parallel being drawn between the bird that was shot by old Werle and sunk in the marsh until retrieved and further lamed by his dog; and the Ekdal family, injured by Werle and hurt even more by the efforts of Gregers to redeem it. English versions of *The Wild Duck* have been made by Mrs. E. Marx-Aveling, Mrs. F. E. Archer and R. F. Sharp.

FRANK W. CHANDLER.

WILD FLOWERS are showy flowering plants growing in nature. The number of different kinds on any continent is reckoned in the thousands. Among them are the ancestors of all our garden ornamental plants, as well as countless other forms which have never been cultivated by man.

National Flowers.—Though the variety of wild flowers is very great, there are certain favorites which have been singled out in nearly every land as national emblems. In England the national flower is the rose, while in Scotland it is the thistle, in Ireland the shamrock, in France the iris, in Switzerland the edelweiss, and in Germany the cornflower. A similar position is occupied by the water lily or lotus in Egypt and in India, by the narcissus in China, and by the cherry blossom in Japan.

State Flowers.—The states and territories of the United States are individually symbolized by state flowers. These state flowers are, with the exception of a few cultivated plants, wild flowers characteristic of the native flora of the state in question. (See FLOWERS, SYMBOLISM OF.—*State Flowers.*)

There is no national flower for the United States. A likely candidate, however, is the red columbine. This graceful plant of woodlands, stream borders, and meadows grows wild in all sections of the United States except the Great Plains. It crosses our borders into Canada and Alaska and ranges for a short distance into Mexico, but is unknown in a wild state in the Old World. It is thus a truly all-American wild flower. Its Latin name, Aquilegia, moreover, is derived from the classical word for eagle, our national bird, while its vernacular name, columbine, is suggestive of Columbus and Columbia.

Buttercup Family.—The columbine is placed by botanists in the buttercup family, which is a way of saying that it is related to buttercups, larkspur, monkshood, and clematis. The members of the buttercup family are mostly herbs with numerous, spirally arranged petals, stamens, and carpels. (See FLOWERS for a description of floral organs.) Buttercups with their shiny yellow petals are common plants of open meadows and marshy fields. There are a number of species of larkspur, all of which may be recognized by the single spur produced at the back of the blue, white, or scarlet flower. The columbine, by contrast, has five floral spurs. Besides the red columbine there are a long-spurred yellow columbine in the mountains of the Southwest and a closely related pale blue form in the Rocky Mountains. The monkshood, which gains its name from the blue, cowl-shaped flowers, is found in moist wooded hills. Its roots contain a deadly poison, which formerly was used in various parts

of the world as an arrow poison. The related magnolia family includes the magnolia and tulip tree of eastern and southern woods.

Rose Family.—The rose family contains numerous native trees, shrubs, and herbs. Their flowers are generally similar to those of the buttercup family except that the carpels are more or less buried beneath the other floral parts. The simple pink blossoms of the wild rose are found in thickets and open woods throughout the United States. The shrubby spirea, amelanchier or serviceberry, hawthorn, thimbleberry, blackberry, wild plum, and chokecherry belong in this family. The wild strawberry, with its creeping stems, white flowers, and small fragrant fruits, is found in moist woods.

Pea Family.—The pea family is distinguished by its fruits, which are dry pods, and by its characteristic flowers, which consist of 3 broadly flaring petals plus 2 smaller petals fused around the 10 stamens and single style. The sweet pea, vetch, and clover are common plants of open fields. The blue and purple flowers of the lupines form large masses of color on open plains and along roadsides. The most popular species of lupine is perhaps the bluebonnet, the state flower of Texas. Locoweed is a beautiful, but sometimes poisonous, plant of the western cattle range.

Violet Family.—The blue and yellow violets of woodlands and meadows and their cousin, the yellow pansy of open fields, are common wild flowers in all parts of the United States. Four states have selected the violet as a state flower.

Heath Family.—The heath family, with 5 petals fused into a tube and 10 stamens, includes the rhodondendron or azalea of our moist woods. The Labrador tea, mountain laurel or kalmia, trailing arbutus or mayflower, blueberry, and cranberry are shrubs of boggy or peatty places in the eastern mountains. The manzanita is a gnarled red-barked shrub of arid western brushlands. Indian pipe and pine drops are brown fleshy herbs of dark forest floors, which live as parasites or saprophytes on roots and leafmold. The striking crimson snowplant of pine woods in California is another such humus plant.

Phlox Family.—The phlox family consists of herbs and showy flowers. The flowers are composed of five petals fused into a tube and five stamens adhering to the petals. There are three carpels fused into an ovary with three stigmas, and the fruit is a three-celled capsule. The phloxes themselves are a large and beautiful group of tall leafy perennials in the woodlands, meadows, and sand dunes of the East; the western species are low, matted, cushiony plants of high mountains. Ranging through the West, the Southwest, and into the South is the scarlet gilia, a perennial herb with brilliant red, trumpet-shaped blossoms. The true gilias, which are annuals with mostly blue-violet flowers, are common wildlings of the western desert plains and mountain slopes.

Snapdragon Family.—The snapdragon family includes many of our most beautiful wild flowers. They are herbs with two-lipped tubular flowers, two or four stamens, and two-celled capsular fruits. The snapdragon, a chiefly Mediterranean group, is not the most conspicuous member of the family with us, being relatively uncommon in the West and absent altogether in the eastern flora. Far more characteristic is the pentstemon, a large assemblage of perennials with showy, blue, red, or white flowers. The monkeyflowers, most of which possess handsome golden-yellow flowers, are common herbs of marshes, streams, and springs. In the Indian paintbrush, a common western wild flower, the tips of the erect bunched shoots are brilliant red. The showy parts here are not the flowers, but the leaves and the bracts subtending them. One species of Indian paintbrush is the state flower of Wyoming. Owl's-clover, toadflax, mullein, veronica or speedwell, and collinsia are other wild flowers belonging in this family. The related bignonia family includes the catalpa, a showy tree of the South.

Mint Family.—The mint family, with square stems, aromatic leaves arranged in pairs, and strongly two-lipped flowers, includes the germander, skullcap, dragonhead, hedge nettle, sage, pennyroyal, and mint.

Sunflower Family.—The sunflower is one of our largest families. These plants are herbs or shrubs with small yellow flowers congested into heads. The familiar "flower" of the sunflower is really an inflorescence composed of numerous tiny flowers. Sunflower seeds were eaten by the Indians and are still used to a limited extent for human food. The goldenrod, which is the state flower of Alabama, Kentucky, and Nebraska, comes into bloom in late summer and fall, when other wild flowers have gone to seed. The goldenrod has long been notorious as a hay-fever plant, but recent studies have shown that it does not deserve its unfavorable reputation. Cornflower, aster, fleabane, everlasting, coreopsis, bur marigold, tarweed, groundsel, thistle, dandelion, and sagebrush are other members of the sunflower family.

Lily Family.—The lily family consists of perennial herbs with bulbs or rootstocks, frequently with ribbonlike or lance-shaped leaves, and with handsome flowers composed of six perianth parts, six stamens, and three fused carpels. Many, like the bog asphodel, tiger lily, and false hellebore, are plants of swampy ground or stream courses. Others such as the fawn lily, fritillary, false Solomon's-seal, and trillium are inhabitants of deep woods, while certain kinds of zygadene, wild onion, and Mariposa lily or calochortus have become adapted to dry hillsides. The native blue and yellow irises belong in the related iris family, and the bizarre treelike yuccas and century plants of the Southwest are classified in another related assemblage, the agave family.

Orchid Family.—The large and interesting orchid family is poorly represented with us. The white, pink, and yellow lady's slippers are plants of rich northern and eastern woods. The rein orchis with small greenish-hued flowers arranged in a spike is found in open woods, meadows, and bogs. Coralroot, a brownish or yellowish herb without green foliage, gains its name from the branching coral-like roots which grow parasitically on the roots of other plants in the forest.

Arum Family.—The arum family, with numerous small flowers crowded on a spike and subtended by a large, often showy, bract, includes several interesting herbs of eastern woods and bogs. Among these are the purple and white jack-in-the-pulpit and the foul-smelling skunk cabbage.

Conservation.—The American countryside was formerly carpeted each spring and summer with wild flowers in indescribable abundance. But, since the coming of the white man and his cattle, the wild flowers have been crowded from their original haunts and restricted, in many

cases to small protected areas. The conservation movement has grown in strength since World War I, and many thoughtful citizens now realize that somewhere a line must be drawn beyond which the destruction of our native wildlife shall not pass. The traditional American custom of gathering armloads of wild flowers for bouquets is prohibited in some states and is everywhere out of harmony with modern conditions.

Collections of dried wild flowers are preserved in museums (or herbaria) in colleges, universities, botanical gardens, and experimental stations throughout the country. Here the specimens are consulted and studied by botanists for compiling regional floras (such as those listed below) or revising and improving the natural classification of any given assemblage of species. Living specimens of wild flowers are preserved in botanical gardens, where they may be viewed by the public. Living wild flowers are grown also in various experimental stations, either as a source of germplasm for the breeding of new ornamental plants or as a means of conducting basic research in botany. See also FLOWERS.

Bibliography.—A knowledge of the names and habits of wild flowers, which increases the pleasure of one's excursions, is naturally a gradual acquisition. The beginner has at his disposal a number of well illustrated books, several of which can be mentioned here: Mathews, F. S., *Field Book of American Wild Flowers* (New York 1912); Armstrong, M., *Field Book of Western Wild Flowers* (New York 1915); Clements, E. S., *Flowers of Coast and Sierra* (New York 1928); Clements, F. E., and E. S., *Rocky Mountain Flowers,* 3d ed. (New York 1928–32); Saunders, C. F., *Western Wild Flowers and Their Stories* (Pasadena 1933); House, H. D., *Wild Flowers* (New York 1935); Sharples, A. W., *Alaskan Wild Flowers* (Stanford, Calif., 1938); Moldenke, H. N., *American Wildflowers* (New York 1949); Zim, H. S., and Martin, A. C., *A Guide to Familiar American Wildflowers* (New York 1950).

One may wish to learn something about the natural relationships of our wild flowers to one another and to the flowering plants of other lands. For this purpose see, among others, the following works: Clements, F. E., and E. S., *Flower Families and Ancestors* (New York 1928); Pool, R. J., *Flowers and Flowering Plants* (New York 1929); Hutchinson, J., *British Flowering Plants* (London 1948).

For a complete catalog of the native wild flowers in any part of the United States one must refer to botanical manuals, such as the following: Coulter, J. M., and Nelson, A., *A New Manual of Botany of the Central Rocky Mountains* (New York 1909); Rydberg, P. A., *Flora of the Rocky Mountains and Adjacent Plains* (New York 1922); Jepson, W. L., *A Manual of the Flowering Plants of California* (Berkeley 1923–25); Kearney, T. H., *Arizona Plants* (Washington Academy of Science Journal 1932); Small, J. K., *Manual of the Southeastern Flora* (New York 1933); Hulten, E., *Flora of Alaska and Yukon* (Lund, Sweden, 1941–50); Peck, M. E., *A Manual of the Higher Plants of Oregon* (Portland 1941); Abrams, L., *Illustrated Flora of the Pacific States,* 4 vols. (Stanford, Calif., 1940–); Britton, N. L., and Brown, A., *An Illustrated Flora of the Northern United States, Canada and the British Possessions,* 3 vols. (New York 1913; reprint 1950); Fernald, M. L., *Gray's New Manual of Botany,* 8th ed. (New York 1950); Kearney, T. H., and Peebles, R. H., *Arizona Flora* (Berkeley, Calif., 1951).

VERNE GRANT,
Rancho Santa Ana Botanic Garden, Claremont, California.

WILD IRISH GIRL, The, a novel by Lady Morgan, published in 1806. It instantly became a favorite in England, went through seven editions in less than two years, and in 1807 reached its fourth American edition. The story is in the form of letters and suffers from the consequent limitations; but the sketches of Irish life are curious and picturesque. It describes the adventures of a young English nobleman who has been banished to his father's estate in Ireland to induce him to become less frivolous and more studious. He falls in love with Lady Glorvina, the wild Irish girl, daughter of the prince of Inismore, but conceals his English identity. He is about to declare his love for her, when he learns that she is promised in marriage to a mysterious stranger. The stranger proves to be the young Englishman's own father, who graciously gives up his claim to the lady's hand when he learns that his now repentant son is the favored suitor.

WILDBAD or **WILDBAD IM SCHWARZLAND,** town, Germany, in southern Württemberg until 1945, when it became Württemberg-Hohenzollern. It is on the Enz River, 12 miles southwest of Pforzheim. It is one of the most frequented spas of the Black Forest. It is a rail terminus, and also is noted for its hot mineral springs. Pop. (1946) 4,999.

WILDCAT, any of the smaller species of feline animals (family Felidae, q.v.) in its feral condition; a lynx. The term is a general one applying to all the smaller felines; but locally has usually some specific application. Thus in European books and speech the "wildcat" properly and ordinarily means *Felis catus,* formerly well known in all forested districts from the British Isles to Siberia, and still to be found in the less settled districts of the Continent south of Sweden, though extinct in Great Britain, France and Italy; it is also numerous in northern Scotland. The wildcat is larger, heavier and more strongly built than the domestic cat (to which it has contributed little, if anything: see CAT), has a stouter head and shorter and thicker tail, which does not taper; besides other peculiarities. Its body is yellowish gray, with a dark stripe along the spine, and with numerous darkish stripes descending more or less vertically down the sides, marking the limbs transversely and forming rings around the tail. It is noted for its savagery, and thoroughly tamed examples are very rare, if any ever existed. Like most of the wild felines the female makes her nest in a hollow tree, or cleft of rocks, in an abandoned crow's nest, or some similarly convenient place, and brings forth there in early summer an annual litter of young, which show the ferocity of their native disposition from the start.

Lynxes.—The other European wildcat and the North American wildcats are lynxes, formerly set apart in a separate genus (*Lynx*); but most modern zoologists do not do so. "The lynxes," says Mivart, "are animals which present a markedly different aspect from that of other cats. Their legs are long, and their tail is, with one exception (that of the caracal), very short. Their ears also are tufted at the tip. The pupil is linear when contracted. The orbits are incompletely surrounded by bone. They have no tooth representing the common cat's first upper premolar, while that answering to its second upper premolar is largely developed. The intestines are also very short. . . . Still the above given characters are variable in the cat group. In some cats other than lynxes the tail is short, and some have the ears more or less penciled. Some, as we have seen, have long legs, and in many the upper premolar is wanting. The lynxes, therefore, cannot be separated off as a nominally distinct group of genus. The lynxes are very variable in their color and markings, and the Northern lynx also varies greatly in the abundance of its hair.

according to the season, the animal having a very different aspect in winter from that which it presents in summer. The Northern lynxes are generally reckoned as forming two species, one belonging to the Old World (*F. borealis*), and at least one species belonging to the New (*F. canadensis*). The American forms are often also described as alone constituting three species — namely, *F. canadensis, F. rufa,* and *F. maculata.* After a careful examination . . . I am, however, not only quite unable to regard the American varieties, as anything more than varieties, but I am inclined to the opinion that there can be no real specific distinctness between the Northern lynxes of the two hemispheres, their skulls as well as their skins being so much alike.»

The European lynx is still found in northern Scandinavia, Russia and eastward, and in some of the wilder mountain chains of central Europe. It is reddish gray, as a rule, indistinctly spotted or not at all, most prominently when young. A large one will measure 40 inches from the snout to the root of the short, thick tail. The lynx of northern America is very similar, the color grading from nearly uniform grizzly gray in far northern specimens which are the largest in average size, toward the reddish and yellowish, more or less spotted southern specimens, which run much smaller: these colors are always brighter in summer than in winter. The long hair depending from the cheeks is characteristic of the group, especially in old males, and gives a very grim aspect to the countenance. These variations, which are local in some of their manifestations, have led the more recent school of American zoologists, led by Merriam, to name several species and subspecies. Thus the Canadian lynx (*F. canadensis*) is not regarded as findable south of Canada, and is characterized by its long gray unspotted coat. The lynxes or «bobcats» of the United States generally are *F. rufa,* yellowish brown spotted on the sides, with dark brown, and having other markings; a subspecies (*maculata*), more profusely spotted, extends the range of the cat to the Pacific Coast; and various other subspecies, distinguished by color, are found in the Gulf States and westward to Central America. All have substantially the same rapacious qualities and habits, varying with the character of the country and climate in which each variety lives, and the kind of small animals upon which they must depend for food. They are chiefly solitary and nocturnal; and soon disappear from all well-settled regions.

African and Asiatic Wildcats.— The Egyptian or gloved cat (*F. caligata*) is the most interesting of the Old World wildcats, because it is the source, or main source, of our domestic races. (See CAT). It inhabits northern Africa, and is about a third smaller than the European wildcat; it is yellowish, growing nearly white on the belly, and has obscure stripings on the body, limbs and tail, which is rather long, slender and tipped with black, while the feet are usually blackish. Another well-known African cat is the large, long-legged serval (*F. serval*) found throughout the whole Continent. It becomes as much as 40 inches long from nose to root of tail, and the tail may be 16 inches in length. In color it is tawny, with black spots, forming two irregular bands along the back, and black rings on the tail; its fur is a valuable commodity. Three or four other species dwell along the West African Coast, as the rare red-brown «golden-haired» cat (*F. rutila*), the smaller gray, spotted, *F. neglecta,* and the more yellowish *F. servalina,* but none is well known.

Asia and the Malayan archipelago have a large number of wildcats, some of which when better known may prove to be more local varieties of other species. The most familiar are the common Indian wildcat (*F. torquata*), which has much resemblance to the European one, but is more slender, a brighter fulvous in tint and less striped. Another wide-ranging species in India is the chaus, or jungle cat (*F. chaus*), about 26 inches long to the tail, which measures 9 to 10 inches and drops to the heels. It is yellowish gray, more or less dark and unspotted, more reddish on the sides, where it unites with the lower parts; a dark stripe extends from the muzzle to the eye, and there are faint bars on limbs and tail. A very similar species, restricted to the arid plains of northern India, is the «ornate» jungle-cat (*F. ornata*). Another large East Indian cat, known from Nepal to Borneo, but nowhere numerous, is called the baycat (F. *aurata*), in reference to its bay-red color, which is unspotted and becomes whitish on the under surfaces. India also has several spotted cats, of which the best known is the widely distributed fishing-cat (*F. viverrina*), which may be 30 to 32 inches long in body, with a tail 9 to 10 inches long; it feeds mainly on fish, snails and other mollusks, yet is noted for its fierceness, and has even been known to seize and carry away small native children. This cat is dark gray in general color, profusely spotted and striped with blackish like a civet. Smaller, more yellowish and much spotted, is the Indian leopard-cat (*F. bengalensis*) which occurs in all parts of India and eastward to Java. Resembling it, but smaller, is the rare wagati; but more distinct and richly ornamented is the tiger-cat (*F. marmorata*), whose tawny coat is marbled or clouded with elongate wavy black lines and commingling spots. It is of small size, but has a very long spotted tail. In the jungles of southern India the sportsman encounters about grassy places a small handsome species, with slender body and head, and rather short legs and long tail, called the rusty-spotted cat (*F. rubiginosa*), which is greenish gray with white under parts, and has dark stripes and lines of small spots extending from nose to rump, and pretty white marks about the face. A similar species (*F. chinensis*) belongs to southern China and Formosa; and several others in the Malayan region. It is quite likely that future increase of knowledge and connecting specimens will bring them all under one name. In Borneo, however, lives a very distinct little cat (*F. badia*), tinted bright chestnut, white on the breast and belly, and without markings, except a few on the face, and a streak on the long tapering tail. The flat-headed cat (*F. planiceps*) of Malacca, Sumatra and Borneo, is another distinct form. It is about the size of a domestic cat, but the body is unusually long, the neck short and thick, the head globular and flat on top, the legs remarkably short and the tail short and thick. Its

fur is dark-brown above, each hair tipped with white, and it is spotted white on the lower parts, with yellow lines forming a V on the face. Central Asia has several notable wildcats, as the manul (*F. manul*), the steppe cat (*F. caudatus*), and Tibetan tiger-cat (*F. scripta*), all of which are handsomely striped or spotted, or both.

American Tropical Cats.—South and Central America are the home of a large variety of small felines, as well as of the puma and jaguar. Of these the most notable are the eyra, ocelot, and jaguarondi (qq.v.) elsewhere described. In addition to these are several of much local interest. The margay or chati (*F. tigrina*) is a widespread and variable species, which is met with from Mexico to Paraguay, in warm and well-wooded lowland regions. Its fur may be a grizzly gray, or vary from that to a fox-red, profusely marked with black spots and rings, which extend along the tail, but do not form rings. There are three upright bars upon each cheek. The margay measures about two feet in length of body, and its tail about 11 inches. Geoffroy's cat (*F. guigna*) is a little known species of southern Brazil. The Pampas cat or straw-cat (*F. pajeras*) is a well-marked form. It is much larger and more robust than a house-cat, with short thick legs, a short, club-shaped tail, thick neck and small head, with great round eyes and very small ears. This appearance of weight and size is largely due to the unusual length of the hair, which is yellowish gray, marked with transverse brownish bands on the body, patches on the face and rings around the tail. It inhabits the open plains of Argentina, and with simlar habits has become a curious counterpart of the manul of the Asiatic steppes.

Bibliography.—Blythe, *Monograph of the Species of Lynx* (Calcutta 1846); Blandford, *Zoology of Persia* (London 1876); Elliot, *Monograph of the Felidae* (London 1878–83); Blanford, *Fauna of British India—Mammals* (London 1888); Mivart, *The Cat* (New York 1892); Hamilton, *The Wildcat of Europe* (London 1896); Stone and Cram, *American Animals* (New York 1902).

WILDE, wild, **George Francis Faxon,** American naval officer: b. Braintree, Mass., Feb. 23, 1845; d. Dec. 3, 1911. He was graduated from the United States Naval Academy in 1864, was attached to the Brazil squadron 1864–66 and received promotion to lieutenant commander in 1869, to commander in 1885, and while commanding the dispatch boat *Dolphin* in 1885–88 made a trip around the world, the *Dolphin* being the first steel vessel in the United States Navy to accomplish that feat. He became captain in 1898, commanded the ram *Katahdin* in the Spanish-American War and later, in command of the *Boston,* he landed the first marine troops ever landed in China, sending them to guard the legation at Peking. He captured Iloilo in the Philippine Islands in 1899, and was placed in command of the *Oregon* in that year. In 1900 he captured Vigan in the Philippines, and he was in command of the *Oregon* when she was grounded on an uncharted ledge of rock in the Pechili Gulf. In 1901–02 he was in command of the navy yard at Portsmouth, N. H., after 1902, at the Boston yard; after 1906 chairman Massachusetts Nautical Training School Commission.

WILDE, Lady **Jane Francesca Elgee** (Speranza), Irish poet: b. Wexford, Ireland, 1826; d. Chelsea, England, Feb. 3, 1896. She was married to Sir William Robert Wills Wilde in 1851. Her literary career began in 1845 with her contributions in prose and verse to the *Nation.* The publication of her essay *Jacta alea est,* under her pen-name "Speranza," was made the basis of the unsuccessful prosecution of the editor after the suppression of the *Nation* in 1848. Her writings include *Ugo Bassi* (1857), *Poems by Speranza* (1871), *Ancient Legends, Mystic Charms, and Superstitions of Ireland* (1887), *Notes on Men, Women and Books* (1891), *Social Studies* (1893).

WILDE, Oscar (Fingal O'Flahertie Wills), Irish poet: b. Dublin, Ireland, Oct. 16, 1854; d. Paris, Nov. 30, 1900. His father was Sir William Wilde, a noted surgeon, and his mother was Lady Jane Wilde (q.v.). He was graduated from Oxford in 1878, winning the Newdigate prize for English verse. In 1879 he went to live in London, where he soon became the leader of the so-called aesthetic movement and was satirized by Du Maurier as "Postlethwaith" in *Punch,* and by Gilbert and Sullivan in the opera *Patience.* He visited the United States in 1882, lecturing extensively on art topics, and later lectured similarly in his own country and in Paris. As an orator he was a flat failure, but he had a faculty of keeping himself in the public eye. In 1895 he was convicted of a serious moral offense and imprisoned for two years. In prison he wrote *A Ballad of Reading Gaol,* a poem of great force, and *De Profundis* (1905). Thereafter he lived mainly in Paris, under the name of Sebastian Melmoth. He also wrote *Poems* (1880); *The Happy Prince and Other Tales* (1888); *Lord Arthur Savile's Crime, and Other Stories* (1891); and the plays, *Guido Ferranti, Lady Windermere's Fan, A Woman of No Importance, The Importance of Being Earnest,* and others. His comedies are extremely clever, and his poems are characterized by melody of movement and beauty of thought. Time has gradually tempered the abuse heaped on Wilde at the time of his conviction. Several of his plays were successfully revived on the New York stage in the late 1940's.

Complete editions of his works: 14 vols. (London 1908); 14 vols. (Boston 1910); 4 vols. (Paris 1936). Biographies and criticism: Sherard, R. H., *The Life of Oscar Wilde* (London 1906); Ransome, A., *Oscar Wilde: A Critical Study* (London 1912); Douglas, Lord Alfred, *Oscar Wilde and Myself* (London 1914); Harris, Frank, *Oscar Wilde: His Life and Confessions,* together with *Memories of Oscar Wilde,* by Bernard Shaw, 2 vols. (New York 1918); Symons, A., *Oscar Wilde: A Study* (London 1930). For Wilde's family see Wilson, T. G., *Victorian Doctor* (New York 1946).

WILDE, Richard Henry, American scholar: b. Dublin, Ireland, Sept. 24, 1789; d. New Orleans, La., Sept. 10, 1847. He came with his parents to the United States in 1797 and settled in Georgia, where he studied law, and in 1809 was admitted to the bar. He was elected attorney general of his state, and in 1815–17, 1824–25, and in 1827–35 was a member of Congress. He spent the years 1835–40 in Europe, made a special study of Dante and Tasso, and was instrumental in the discovery of a portrait of Dante by Giotto on the wall of the chapel of Bargello. He subsequently

removed to New Orleans, re-engaged in law practice, and in 1844 accepted the chair of constitutional law at the Louisiana State University. He wrote the widely popular poem, *My Life is Like the Summer Rose,* and also published *Conjectures and Researches Concerning the Love, Madness and Imprisonment of Torquato Dante* (1842). His poem *Hesperia,* edited by his son, was published in 1867.

WILDE, Thomas. See TRURO, THOMAS WILDE, BARON.

WILDER, wĭl'der, **Alexander,** American physician and author: b. Verona, N.Y., May 14, 1823; d. Sept. 19, 1908. He was graduated at Syracuse Medical College in 1850, and in 1852 began an editorial career on the Syracuse *Star* being subsequently connected with the Syracuse *Journal* (1853), New York *Teacher* (1856), and New York *Evening Post* (1858–1871). He was an anti-Tweed alderman in New York in 1872, inspector of schools in 1873, and from 1875 to 1895 secretary of the National Eclectic Medical Association. He was president of the New York School of Philosophy.

WILDER, Burt Green, American scholar and physiologist: b. Boston, Mass., Aug. 11, 1841; d. Jan. 22, 1925. He was graduated from the Lawrence Scientific School at Harvard in 1862, was assistant surgeon in the Union army in 1863–1865, and in 1866 was graduated from the medical department at Harvard. He was assistant in comparative anatomy at the Harvard Museum of Comparative Zoology in 1866–1867, and in 1867 accepted the chair of zoology at Cornell, which he occupied until 1916, when he was made professor emeritus.

WILDER, Marshall Pinckney, American horticulturist: b. Rindge, N.H., Sept. 22, 1798; d. Boston, Mass., Dec. 16, 1886. He was engaged as a merchant in the West India trade at Boston after 1825, in 1839 was chosen to the State legislature, was president of the State senate in 1850, and in 1849 served as member of the executive council. He was prominent in the organization of the Constitutional Union Party, was a delegate to the convention which nominated Bell and Everett in 1860, and throughout the Civil War was a firm supporter of the Union. He founded the Massachusetts Agricultural Society, the Massachusetts Agricultural College, and was active in establishing the Massachusetts Institute of Technology.

WILDER, Marshall Pinckney, American professional entertainer: b. Geneva, N.Y., Sept. 19, 1859; d. Jan. 10, 1915. His occupation was at first a peddler, and later a stenographer, but he abandoned it in order to become a drawing-room entertainer, in which capacity he became widely popular. Though a hunchback he possessed such a pleasing presence with unfailing good humor that he made friends everywhere. At first he entertained for 50 cents an evening, but in 1883 he went to London, was well received by royalty, and his fame was thus established. In 1899 he began to appear in vaudeville. In 1904–1905 he toured around the world. He published *People I've Smiled With; The Sunny Side of the Street* (1905); *Smiling Around the World* (1907).

WILDER, Thornton Niven, American author: b. Madison, Wis., April 17, 1897. He spent part of his childhood in Hongkong and Shanghai, because his father was in the consular service. He later went to school in California and attended Oberlin College from 1915 to 1917. During World War I he served in the coast artillery and then was graduated from Yale University in 1920. After a period of study at the American Academy in Rome, he taught at Lawrenceville Academy for seven years, received a master's degree at Princeton University in 1925, and was a lecturer in English at the University of Chicago.

Mr. Wilder's first published work was a novel, *The Cabala* (1926), followed by *The Bridge of San Luis Rey* (1928) which won the Pulitzer Prize in 1928 as the best novel of the year. His other published fiction includes *The Woman of Andros* (1930) and *Heaven's My Destination* (1935). He had long been interested in playwriting, and as early as 1926 his play *The Trumpet Shall Sound* was produced by the American Laboratory Theatre. His first play to be famous was *Our Town,* which was awarded the Pulitzer Prize in 1938 as the best play of the year, making him the first writer to receive the award in two different literary fields. *Our Town* was an experimental drama, performed on an almost bare stage, with stepladders to indicate the upstairs of a house and a group of folding chairs for a graveyard. In addition to highly successful adaptations that he has made of *A Doll's House* and *Lucrece,* Mr. Wilder has written two other plays, *The Merchant of Yonkers* (1939) and *The Skin of Our Teeth* (1942), the latter winning him a third Pulitzer Prize. See also BRIDGE OF SAN LUIS REY, THE; OUR TOWN; also DRAMA—*Modern* (United States); NOVEL—*Modern* (American).

WILDERNESS, The Battle of the. On March 9, 1864, President Lincoln handed to General Grant his commission as lieutenant general and two days later placed him in command of all the armies of the United States. Grant made immediate preparations for an early campaign to be conducted simultaneously, east and west. He made his headquarters with the Army of the Potomac. Before coming to the East he had expressed himself as favoring a coast movement south of James River, and an advance on Richmond on that line. After his arrival at Washington and a study of the problem he proposed to act with the Army of the Potomac on what was known as the overland route from the Rapidan to the James, while General Butler, with 30,000 men, should ascend James River from Fort Monroe and establish himself in an intrenched position near City Point, whence he could operate against Richmond and its communications with the south, and at a proper time form a junction with the Army of the Potomac, moving down from the north. At the same time General Sigel, commanding troops in West Virginia and the Shenandoah Valley, was instructed to form two columns, one of 10,000 men, under General Crook, to move from the Kanawha and operate against the Virginia and East Tennessee Railroad, the other 7,000 strong, under Sigel, in person, to advance, as far as possible, up the Shenandoah Valley, to draw detachments from Lee. Grant's main reliance, however, was the

Army of the Potomac, which, 30 April 1864, was composed of the Second, Fifth and Sixth corps of infantry and a cavalry corps, commanded respectively by Gens. W. S. Hancock, G. K. Warren, John Sedgwick and P. H. Sheridan. The Ninth corps, Gen. A. E. Burnside, united with the Army of the Potomac on 6 May, but acted under the immediate orders of General Grant, until the 24th, when it became a part of the Army of the Potomac.

The strength of the army, including the Ninth corps, 30 April, was 118,769 officers and men, with 316 guns. The army was commanded by Gen. George G. Meade. Formed in battle line, two ranks deep, with one-third in reserve, it would cover a front of 21 miles. Its train of 4,000 wagons was 65 miles long. The assigned duty of this army was to attack the Army of Northern Virginia, and by constant hammering destroy it and take Richmond. The army of Northern Virginia, commanded by Gen. R. E. Lee, was composed of the First, Second and Third infantry corps, commanded by Gens. J. Longstreet, R. S. Ewell and A. P. Hill. A cavalry corps of two divisions (Wade Hampton's and Fitzhugh Lee's) was commanded by Gen. J. E. B. Stuart. The most reliable estimate gives Lee's strength, present for duty, on 1 May 1864, as 48,700 infantry, 4,854 artillery and 8,399 cavalry, an aggregate of 61,953 officers and men, with 224 guns. On 1 May the Army of the Potomac was encamped in the vicinity of Culpeper Court House, between the Rapidan and the Rappahannock, and the Ninth corps on the railroad from Manassas Junction to the Rappahannock. Lee's army lay south of the Rapidan, Ewell's corps above Mine Run and A. P. Hill's on Ewell's left, higher up the Rapidan. Longstreet's corps was near Gordonsville. Stuart's cavalry lay along the lower Rappahannock. Lee's headquarters were near Orange Court House, 70 miles from Richmond.

Lee's army being the first objective, it was finally determined to cross the Rapidan, turn his right and compel him to fall back toward Richmond or come out of his intrenchments and give battle on open ground. The principal objection to this movement was the difficulty presented by the Wilderness, a forest of unusually dense growth, with an almost impenetrable undergrowth, where infantry could pass with great difficulty and where cavalry and artillery could not be used. It was thought to avoid this difficulty by moving at night, crossing the Rapidan and getting through the Wilderness before Lee could discover the movement and intercept it by moving on the Orange turnpike and Orange plankroad. These two roads lead from Orange Court House down the Rapidan toward Fredericksburg. They follow the general direction of the river and are almost parallel to each other; the turnpike nearest the river and the plank road a short distance south of it. Grant's proposed route lay directly across these two roads along the western borders of the Wilderness. The movement began at midnight of 3 May. Hancock's Second corps, preceded by Gregg's cavalry division, crossed the Rapidan at Ely's Ford and moved to Chancellorsville, where the entire corps with its trains had arrived by noon of the 4th. Warren's corps, preceded by Wilson's cavalry, crossed the river at Germanna Ford and marched to Wilderness Tavern, at the intersection of the Germanna road by the Orange turnpike. It reached its position by 2 P.M. of the 4th.

Wilson's cavalry was thrown forward to Parker's Store on the Orange plankroad. Sedgwick's Sixth corps followed Warren's across the Germanna Ford and halted a short distance beyond it. The crossing of the river was very gratifying to Grant who regarded it as a great success, and it removed from his mind the most serious apprehension he had entertained "that of crossing the river in the face of an active, large, well-appointed and ably commanded army, and how so large a train was to be carried through a hostile country and protected." At noon of the 4th Grant knew that Lee was aware of his movement, upon which he sent a dispatch to Burnside to make a forced march from beyond the Rappahannock to Germanna Ford, and by the morning of the 5th his advance was crossing the Rapidan. The orders for the 5th were for Sheridan, with two divisions of cavalry, to move against the Confederate cavalry, near Hamilton's Crossing, and at 5 A.M. Wilson's cavalry division was to move to Craig's Meeting House and reconnoitre the Orange pike and plankroads and other roads on his right and left. Hancock's Second corps was to march from Chancellorsville to Shady Grove Church and extend its right toward Parker's Store on the Orange plankroad, to which point Warren's corps was ordered to advance from Wilderness Tavern. Warren, in turn, was to extend his right toward Sedgwick's Sixth corps, which was ordered to Wilderness Tavern.

General Lee interfered with the full execution of these orders. He had been expecting Grant to move on his right and when he saw on the morning of the 4th that the movement was being made, determined to attack him before he could get out of the Wilderness and ordered Ewell to march by the Orange pike and A. P. Hill down the plankroad, and that night Ewell bivouacked within five miles of Wilderness Tavern, and Hill's advance division halted for the night at Mine Run, seven miles from Parker's Store on the plankroad, and about 10 from the intersection of the Brock road. Longstreet moved from near Gordonsville at 4 P.M. Stuart's cavalry was drawn in and ordered to cover the Confederate right. On the morning of the 5th Ewell continued his march on the Orange pike, under instructions to regulate his march with that of A. P. Hill, on the plankroad, and both informed that it was not desired to bring on a general engagement before Longstreet came up, who was under orders to follow Hill on the plankroad. When Ewell was two miles from the Wilderness Tavern, he halted, as he was three or four miles farther advanced than Hill. Warren had discovered that the Confederates, under Ewell, were in force two miles beyond Wilderness Tavern and before 7 A.M. had informed Meade of the fact, who ordered Warren to make an attack with his whole force. Sedgwick was directed to move up by a cross road, attack the enemy and connect with Warren on the turnpike, and a dispatch was sent to Hancock, informing him of what had become known and directing him to halt at Todd's Tavern, until further de-

velopments. Warren had started early in the morning for Parker's Store, on the Orange plankroad, and when near it Crawford's division had been ordered to halt in a good position on high ground, and finding that Wilson's cavalry at Parker's Store needed assistance Crawford threw forward a skirmish line that encountered the flankers of A. P. Hill's corps.
